Cellulose derivatives. SOC. POUR L'IND. CHIM. À BÂLE. Fr. 687,301, Dec. 27, 1929. New cellulose derivs. are prepd. by treating active cellulose, such as cellulose treated with caustic alkalies, with heterocyclic compds. contg. one or more NC-halogen groups, and, if desired, causing the products to react with compds. contg. atoms capable of reacting with the products. Thus, active cellulose is treated at 25–40° in a soln. of cyanuric chloride in xylene in the presence of chalk powder. The product may be dyed with basic dyes but not with acid or direct dyes. Examples are also given of the use of cyanuric bromide, the hydrazide of dichloromaleic acid, dichloroquinazoline and piperazine and of the dyeing of these products. Cf. *C. A.* **25**, 591.

Cellulose acetate. SOC. KODAK PATHÉ (SOC. ANON. FRANÇAISE). Fr. 687,084, Dec. 21, 1929. Cellulosic material is treated with a soln. of a lower aliphatic acid satd. with N_2O_4, until the soly. of the product in potash reaches at least 15%, and acetylating in a bath contg. Ac_2O and H_2SO_4 or H_3PO_4. Cf. *C. A.* **24**, 6014.

Cellulose butyrates. SOC. DES BREVETS ÉTRANGERS LEBLANC ET CIE. Fr. 686,906, Mar. 14, 1929. Cellulose butyrates, particularly triisobutyrates and tributyrates, are prepd. by submitting the cellulose material to the regulated action of a Cl deriv. of AcOH, in the presence of a suitable solvent such as butyric acid or acetone at a low temp., and esterifying at 15–25° in the presence of a dehydrating agent such as 66° Bé. H_2SO_4 and an appropriate solvent.

Benzylcellulose, etc. IMPERIAL CHEMICAL INDUSTRIES, LTD., and D. TRAILL. Brit. 333,902, Feb. 20, 1929. In order to improve their solubilities in cheap solvents such as benzene, toluene or xylene mixed with "industrial spirits," benzylcellulose or other aralkyl ethers of cellulose, not readily sol. in such solvents, are treated with benzyl chloride or other aralkyl halide and water and steam at increased pressure (suitably 50 lb. per sq. in. for an hr.). Products thus treated give solns. of reduced viscosity suitable for use in *lacquers* or for various other purposes. Details of procedure are given. Cf. *C. A.* **24**, 5157.

Solvent for derivatives of cellulose. WILLIAM H. MOSS (to Camille Dreyfus). Can. 306,829, Dec. 16, 1930. A solvent for derivs. of cellulose comprises methylene chloride and an aliphatic alc. having more than two C atoms. Cf. *C. A.* **24**, 1740.

Nitrocellulose. WESTFÄLISCH-ANHALTISCHE SPRENGSTOFF-A.-G. CHEM. FAB. Ger. 509,348, May 28, 1929. Plates or boards of compressed cellulose are hung in a nitrating vessel, which is closed and evacuated before admission of the acid.

Acetylating nitrocellulose. HENRY A. GARDNER and CALVIN A. KNAUSS (to Henry A. Gardner Laboratory, Inc.). U. S. 1,786,989, Dec. 30. Ethylene dichloride

is added to a soln. of acetylated nitrocellulose in a solvent comprising HOAc, and the resulting pptd. acetylated nitrocellulose is sepd.

Cellulose esters. I. G. FARBENIND. A.-G. Fr. 687,627, Jan. 3, 1930. Mixed cellulose esters of org. acids are made by treating cellulose in a diluent with a free acid or its anhydride and the halide of another acid, in the presence of tert. bases, the amt. of which is less than the total amt. corresponding to the acid and acid derivs. present. Examples are given.

Cellulose esters. SOC. DES BREVETS ÉTRANGERS LEFRANC ET CIE. Fr. 687,169, Mar. 16, 1929. Mixed esters of cellulose are made by treating cellulosic materials with a Cl deriv. of AcOH at a low temp. in the presence of a solvent such as AcOH or butyric acid, and then esterifying with a mixt. of butyric anhydride and Ac_2O in the presence of H_2SO_4.

Cellulose esters. SOC. KODAK PATHÉ (SOC. ANON. FRANÇAISE). Fr. 687,996, Jan. 10, 1930. Mixed esters of cellulose which are insol. in acetone and in C_6H_6 are prepd. by treating cellulose material with an acyl halide selected from the group which consists of the halides of the aralkyl monocarboxylic acids, the aromatic monocarboxylic acids, and the aliphatic monocarboxylic acids including the cycloparaffinic, and subsequently treating the product with an acylating agent which contains a smaller no. of C atoms than the acyl halide. The second treatment may be carried out in the presence of tetrachloroethane or $CHCl_3$, and the first in the presence of pyridine or C_6H_6. Examples are given of the prepn. of acetostearates. The products may be used for making *plastic compns.* in *varnishes*, etc., in *artificial leather*, as a coating for fabrics and in *artificial silk*.

Cellulose esters. SOC. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 688,601, Jan. 21, 1930. Cellulose esters are made by treating cellulosic material with a soln. of HNO_3 (sp. g. 68%), washing and dehydrating, and heating the cellulose thus hydrolyzed with a fatty acid contg. more than one and less than 8 C atoms in the presence of a catalyst at a temp. of 100–170° until $2^1/_2$–3 mol. proportions of the said fatty acid are combined with a quantity of cellulose corresponding to 24 atoms of C.

Cellulose ether solutions. ARTHUR EICHENGRÜN. Ger. 508,153, Aug. 11, 1922. Solns. of aliphatic or aromatic ethers of cellulose are prepd. with a solvent comprising CH_2Cl_2 alone or mixed with EtOH, $C_2H_4Cl_2$, or other cellulose-ether solvents or non-solvents.

Residues from the saccharification of wood. HOLZHYDROLYSE A.-G. Fr. 688,507, Jan. 20, 1930. Deacidified residues from the saccharification of wood or other vegetable materials by acid are agglomerated by compression and used directly as *fuel* or as a *construction material*, or are carbonized after mixing with fine coals, or are mixed with other construction materials.

Apparatus for suppressing malodorous gases produced in the manufacture of cellulose by the sulfate or soda process. BROR NATANAEL SEGERFELT. Fr. 687,335, Dec. 2, 1929. The gases are cooled to their dew point or satd. with water and treated with substances which oxidize, absorb or combine with the gases. The gases may be given a preliminary treatment by passing them through alk. solns. and combustible gases may be removed by burning.

Desulfurizing articles of regenerated cellulose. WILHELM ELLER and TOTILA MADELUNG (to I. G. Farbenind. A.-G.). U. S. 1,786,941, Dec. 30. Products of regenerated cellulose obtained by coagulation from a viscose soln. are treated with a soln. of the strongly colored by-products contained in crude cellulose xanthate (which soln. may be prepd. by extn. with MeOH).

Fabric comprising regenerated cellulose. MILTON J. SHOEMAKER (to C. F. Burgess Laboratories, Inc.). U. S. 1,786,781, Dec. 30. See Brit. 317,330 (*C. A.* **24**, 2296).

Viscose for artificial-silk manufacture. FRANZ STEIMMIG and ERSTE BÖHMISCHE KUNSTSEIDEFABRIK A.-G. Fr. 687,353, Dec. 28, 1929. See Brit. 332,628 (*C. A.* **25**, 414).

Regenerating viscose spinning baths. HENRY MOLINARI. Ger. 509,430, Aug. 26, 1928. In regenerating spinning baths comprising H_2SO_4 and Na_2SO_4, the spent bath liquor is removed into an unpacked tower down which it falls freely in counter current to hot combustion gases. The sulfate sepg. from the concd. liquor is removed. App. is described.

Desulfurizing viscose products. HERMINGHAUS & CO. G. M. B. H. Ger. 508,013, Mar. 25, 1929. An org. solvent for S, or a soln. of an inorg. or org. desulfurizing agent in an org. solvent or solvents, is used. The soln. may contain a small quantity of water. Suitable reagents are PhOH 1 dissolved in EtOH 4 parts, pyridine, or a soln. of glycerol MeOH or EtOH 5 parts.

Filaments, films, etc., from viscose. CHEM. FAB. POTT & Co., and FRIEDRICH POSPIECH. Ger. 509,375, June 18, 1925. Alkylnaphthalenesulfonic acids or their salts are added to the viscose soln. and (or) to the pptg. bath in an amt. up to 3%.

Artificial silk from viscose. TOSHIYA IWASAKI. Ger. 509,295, Sept. 3, 1926. See Brit. 288,655 (*C. A.* **23**, 705).

Artificial silk from viscose. J. G. FARBENIND. A.-G. Brit. 334,030, Oct. 2, 1928. Viscose made from unripened alkali cellulose and contg. an excess of alkali (such as a viscose contg. 5% of cellulose and 6.5% of alkali) is spun (suitably at a temp. of 50°) into a bath contg. H_2SO_4 of not over 47% strength, which may also contain salts such as Na_2SO_4 or org. substances. It is preferable to prep. the viscose in an inert atm. such as N, and addns. such as reducing agents, mordanting agents, mucilage, oxalates, lactates, silicates, sulfonic acids or substances for producing mat or aerated effects may be made.

Artificial silk from viscose solutions. C. F. M. VERSTIJNEN. Brit. 333,977, June 6, 1929. Products of reduced luster are obtained from viscose solns. by adding chemically inert substances emulsifiable with the soln., as by homogenizing with 0.5–0.8% of a mixt. of benzene or toluene and CCl_4 having about the same sp. gr. as the soln.

Magnesium sulfate from waste water of artificial-silk factories, etc. EMILIO RODOLFO. Ger. 509,602, Dec. 8, 1928. See Brit. 331,648 (*C. A.* **25**, 175).

Rayon. GEORGE A. RICHTER (to Brown Co.). Can. 305,135, Oct. 28, 1930. Rayon filaments are spun in an acid setting bath of comparatively high H_2SO_4 content and at above room temp. and the acid is removed from the filaments as they progressively issue from the bath.

Rayon. GEORGE A RICHTER (to Brown Co.). Can. 306,064, Nov. 25, 1930. Rayon filaments are spun into a setting bath contg. H_2SO_4, the acid-soaked filaments are lead through an alc. bath (glycerol) to dil. the acid, and the filaments are then wound.

Rayon filaments. ARTHUR E. GUENTHER and HARRY S. TOOLE (to DuPont Rayon Co.) U. S. 1,787,575, Jan. 6. Mech. features.

Artificial silk. FRANZ J. GAHLERT. Ger. 509,634, Dec. 11, 1926 and 509,635, May 31, 1927. Addns. to 472,113 (*C. A.* **23**, 3111). In after-treating artificial silk threads as described in Ger. 472,113, caustic soda soln. is used as the softening agent (509,634). A size, *e. g.*, starch or gelatin, may be added to the softening bath (509,635).

Artificial silk. MAURICE LEON and HARBEN'S (VISCOSE SILK MANUFACTURERS), LTD. Ger. 509,429, Dec. 30, 1928. See Brit. 325,617 (*C. A.* **24**, 4157).

Artificial silk. SOC. POUR LA FABRICATION DE LA SOIE "RHODIASETA." Ger. 508,070, Dec. 20, 1927. Spinning solns. yielding dull, weighted filaments are prepd. by pptg. a cellulose ester or ether from a soln. in which $BaSO_4$ or other white salt insol. in water has been formed by chem. reaction, then washing and drying the pptd. product, and prepg. the spinning soln. therefrom in the usual manner. The formation of the salt and the pptn. of the ester or ether may proceed at the same time, *e. g.*, by adding a soln. of $BaCl_2$ in dil. AcOH to an acetylation mixt. to which H_2SO_4 has been added, if necessary.

Artificial silk. STECKBORN KUNSTSEIDE A.-G. Swiss 134,056, Feb. 23, 1929. Matt effects are produced by mixing a finely divided non-reactive ether, of about the same sp. gr. as the viscose, with the silk. Benzyl ethers are mentioned in the example.

Artificial silk, etc. PIERRE L. E. V. BOURGEOIS Fr. 688,420, Jan. 18, 1930. Dextrin is added to viscose to be used for the manuf. of artificial silk, to obtain a larger wt. of fixed cellulose.

Artificial silk. I. G. FARBENIND. A.-G. Fr. 686,922, Dec. 18, 1929. Artificial silk, stable to boiling and resistant to the action of soap and alkalies, is made from cellulose esters contg. besides AcOH about 0.2 mols. or more of a higher fatty acid, such as butyric or propionic acid, to 1 mol. of cellulose ester.

Artificial silk. I. G. FARBENIND. A.-G. Fr. 687,093, Dec. 21, 1929. The elementary strands prepd. by spinning from transformation products of the polymerization products of butadiene hydrocarbons (cf. Fr. 674,679, *C. A.* **24**, 2846) or rubber or mixts. thereof with or without other substances are used for the manuf. of artificial silk.

Artificial silk. KABELFABRIK A.-G. and SOIERIES DE STRASBOURG (SOC. ANON.). Fr. 688,211, Jan. 14, 1930. Pneumatic means is described for removing the cake of silk from the spinning pot.

Artificial silk. OSCAR KOHORN & Co. and ALFRED PERL. Fr. 686,783, Dec. 17, 1929. In artificial silk manuf. from ammoniacal-CuO soln., the action of the hardening liquid on the thread is limited to the time necessary for the thread to pass through the

bath, by washing off or otherwise removing the liquid from the thread immediately after it leaves the bath.

Artificial silk. OTTO SCHWARZKOPF and ALEXANDER ALBRECHT. Fr. 687,098, Dec. 21, 1929. The cake of silk obtained in pot-spinning is pressed tightly between plates, the lower one of which has inlet and outlet openings for liquids, the sides of the cake thus forming a container for the treating liquids.

Artificial silk. SAMUEL WILD. Fr. 687,805, Jan. 7, 1930. Means for cooling the spinning nozzles is described.

Films. ZELLSTOFFFABRIK WALDHOF and ARNOLD BERNSTEIN. Fr. 687,324, Dec. 27, 1929. Films or sheets are made from viscous solns. (cellulose, cellulose compds., gelatin, etc.) by passing the soln. down between 2 cylinders rotating in opposite directions, and sufficiently apart to allow a film of the desired thickness to pass. The film is solidified by coagulation on one of the cylinders which dips into a pptn. bath.

Films from plastic materials. SOC. DES USINES CHIM. RHÔNE-POULENC. Fr. 688,200, Jan. 14, 1930. Films or sheets are drawn from plastic material having a basis of cellulose esters or ethers, at a temp. near that at which the plastic material used softens and tends to become liquid. The film is carried away by rollers turning at different speeds.

Artificial filaments, films, ribbons, etc., from cellulose esters and ethers. H. DREYFUS. Brit. 333,926, May 17, 1929. The solvent medium described in Brit. 312,-203 (*C. A.* **24**, 963) is modified so that the relative proportions of the non-solvent liquid or liquids and of the volatile substances or substances are such that together they do not form a solvent for the cellulose deriv., and one or more solvents of high b. p. are used in sufficient quantity to give solvent properties. Various examples are given.

Artificial threads, films, etc. HENRY DREYFUS. Fr. 687,471, Dec. 31, 1929. Threads films, etc., are made from solns. of cellulose esters by spinning or molding followed by a superficial or partial sapon. by NaOH, etc.

Producing artificial-silk filaments. GIOVANNI LUCHSINGER. Swiss 138,678, Mar. 13, 1929. Details of the app.

Artificial fibers by the wet-spinning and stretching method. NOVASETA A.-G. ARBON. Swiss 140,048, July 11, 1929. Details are given.

Artificial-silk thread by the spinning-head method. I. G. FARBENIND. A.-G. (Paul Esselmann and Walther Schieber, inventors). Ger. 509,836, June 4, 1929. Details of tensioning and spinning the filaments are given.

Apparatus for making artificial silk. FR. KÜTTNER A.-G. Ger. 508,592, Nov. 19, 1929. Addn. to 482,068 (*C. A.* **24**, 501).

Spinning apparatus for artificial silk. STECKBORN KUNSTSEIDE A.-G. Swiss 137,993, April 5, 1929.

Spinning device for artificial silk. HARBENS, LTD., and LESLIE C. GOODWIN. Ger. 509,966, Sept. 1, 1929. A device is described for deaerating the spinning-head chamber.

Spinning device for artificial silk. MORRIS SCHOENFELD. Swiss 135,715, Jan. 14, 1929.

Spinning machine for artificial silk. CARL HAMEL A.-G. Ger. 506,976, April 14, 1929.

Spinning machine for artificial silk. I. G. FARBENIND. A.-G. (Rudolf Grützner, inventor). Ger. 508,267, April 2, 1927. See Brit. 288,153 (*C. A.* **23**, 514).

Funnel spinning device for artificial silk. FRITZ TSCHIRCH. Ger. 509,636, June 7, 1928. Details of arrangement.

Centrifugal spinning machine for artificial silk. SOCIÉTÉ DE LA VISCOSE SUISSE. Swiss 138,557, May 7, 1929.

Electrically driven spinning device for artificial silk. MASCHINENFABRIK OERLIKON. Swiss 137,712, Mar. 15, 1929.

Spinning tubes for artificial silk. W. C. HERAEUS G. M. B. H. Fr. 688,002, Jan. 10, 1930. Spinning tubes for artificial silk are made from alloys of noble metals such as Au or Pt with Si, Al or an alk. earth metal including Mg. Up to 10% of Ni, Fe, Cr, Ta or Tu may also be added.

Spinning pot for artificial silk. SIEMENS-SCHUCKERTWERKE A.-G. (Wilhelm Stiel, inventor). Ger. 508,194, Oct. 21, 1928. A spinning pot is provided with a flexible insertion, *e. g.*, of paper, of such dimensions that it can be packed around the spun cake.

Removable insertion for artificial silk spinning pot. I. G. FARBENIND. A.-G. (Richard Hofstadt, Totila Madlung and Hubert Rein, inventors). Ger. 508,268, Dec. 12, 1928.

Dry-spinning apparatus for artificial silk. ACETA G. M. B. H. Ger. 508,113, June 25, 1927. A construction of spinning cell is described.

Dry-spinning artificial silk. ERNST BERL. Ger. 506,975, Mar. 25, 1928. Filaments pass down a cylinder contg. drying gases.

Dry-spinning artificial fibers. LONZA ELEKTRIZITÄTSWERKE UND CHEMISCHE FABRIKEN A.-G. and NOBILE CARLO THOMMASI. Swiss 139,145, May 12, 1928.

Apparatus for dry spinning of artificial silk from cellulose acetate. O. VON KOHORN (trading as O. Kohorn & Co.) and H. SCHUPP. Brit. 334,109, Nov. 15, 1928. Pins or pencils carrying soap or oil are used for cleaning spinning nozzles. Various details of app. are described.

Spindle for artificial fibers, especially artificial silk. PAUL LIEBSCHER and KARL KOSKE. Ger. 507,938, Feb. 7, 1929.

Funnel for making artificial silk by the stretch-spinning method. FR. KÜTTNER A.-G. Ger. 509,294, May 27, 1928.

Device for the simultaneous heating of a battery of spinning shafts for artificial fibers. ACETA G. M. B. H. Ger. 508,591, June 10, 1928.

Apparatus for regulating the supplementary treatment of artificial silk in a hardening or precipitation bath. OSCAR KOHORN & Co. and ALFRED PERL. Fr. 687,632, Jan. 3, 1930.

Apparatus for washing and after-treating cakes of artificial silk. HANS EGGERT. Ger. 508,012, Dec. 23, 1926.

Pulp manufacture. LINN BRADLEY and EDWARD P. MCKEEFE (to Bradley-McKeefe Corp.). Can. 306,941, Dec. 23, 1930. Raw cellulosic material is digested in an alk. liquor contg Na_2SO_3, the spent liquor is concd., the combustible content burned and the inorg. content heated to produce Na_2S and Na_2CO_3. These are dissolved in water and the soln. is treated with CO_2 to produce pure H_2S and convert all the Na_2S to Na_2CO_3. The H_2S is recovered as Na salt and the Na_2CO_3 soln. is treated with SO_2 to produce substantially pure CO_2 and Na_2SO_3 soln. The CO_2 obtained is used for the carbonation of another batch. Cf. *C. A.* **24**, 4158.

Machine for cleaning old paper, rags, etc. AUGUST AELDERT. Ger. 508,356, Aug. 19, 1927.

Digesting raw cellulosic material such as wood. GEO. A. RICHTER (to Brown Co.). U. S. 1,787,953, Jan. 6. Material such as wood is cooked in a H_2SO_3 liquor, residual H_2SO_3 groups in the liquor are oxidized (suitably by NaOCl or Na_2O_2) and the liquor is rendered alk. (suitably by the addn. of NaOH) and the cellulosic material is further cooked in the alk. liquor. U. S. 1,787,954 relates to a process in which the cellulosic material is cooked in H_2SO_3 liquor, the liquor is neutralized while the S content is maintained in combined state, and alk. substances including Na sulfide are added to render the liquor alk., followed by further cooking of the cellulosic material in the alk. liquor. Cf. *C. A.* **25**, 593.

Separating long fibers from materials such as wood-pulp suspensions. ROBERT A. WEBBER (to Brown Co.). U. S. 1,786,973, Dec. 30. Mech. features.

Pump for conveying thick wood pulps or similar materials. A. FROISLAND and K. MORCH. Brit. 334,135, May 1, 1929. Structural features.

Chemical pulp for paper making. FRANK A. JOHNSON (one-fourth each to John H. O'Connell, John D. Haskell and Dilts Machine Works, Inc.). U. S. 1,786,538, Dec. 30. Chem. pulp is subjected to a grinding (as distinguished from beating) operation and the character of the grinding stones is varied in accord with the character of paper to be produced and freeness tests are applied at the point of grinding and the pressure of the pulp against the grinders is varied and water is introduced in accord with the requirements of the particular pulp under treatment and the product desired.

Bleaching pulp. ERIC WAHLFOROSS (to Industrial Processes, Ltd.). Can. 305,908, Nov. 18, 1930. Pulp is impregnated with an aq. soln. of H_3PO_2 to react upon the Fe in the pulp to form $FePO_2$, which is stable to the action of light and atm. conditions.

Bleaching paper pulp. ROBERT B. WOLF and RAYMOND S. HATCH (to The International Bleaching Corp.). Can 307,171, Dec. 30, 1930. Pulp is initially treated at low concn. and ordinary temp. with 20–40% of the $Ca(ClO)_2$ required to complete the bleaching. The released impurities are washed from the pulp and it is then further bleached at high concn. and at a temp not exceeding 80°F.

Dewatering paper pulp, etc., by pressing. RICHARD KASTNER and HERBERT SCHMOLKA. Ger. 509,455, June 21, 1927. This corresponds to Austrian 115,901 (*C. A.* **24**, 2295) but gives addnl. details.

Paper. JOHN TRAQUAIR (to Mead Pulp & Paper Co.). U. S. 1,786,681, Dec. 30. A formed sheet of wet paper has incorporated with it a paper surface layer of desired

character before it is passed to the driers, by flowing on to it a liquid stock suspension contg. fibrous material. An arrangement of app. is described.

Paper. ROBERT B. WOLF. Ger. 507,585, Dec. 31, 1925. An app. is described for treating wood pulp, etc., mixed with a bleaching agent and with air at reduced pressure for paper-manuf.

Paper. BRITISH AMERICAN TOBACCO CO., LTD. Fr. 688,350, Jan. 16, 1930. The tendency of cigaret paper to change color and become stained with tobacco is prevented by incorporating in the paper during or after its manuf. a fatty material such as stearin.

Roll suitable for paper-making apparatus. FREDERICK R. WOODWARD (to Stowe & Woodward Co.). U. S. 1,787,890, Jan. 6. Pieces of rock forming a portion of the active surface of the roll are held in position by a binder of other material such as rubber.

Hydraulic calendering rollers for paper manufacture. JOSEPH ECK & SÖHNE. Ger. 507,766, Feb. 5, 1929.

Paper machine. WM. H. MILLSPAUGH. Ger. 507,588, Sept. 25, 1929. Details are given.

Long sieve paper machine. F. H. BANNING & SEYBOLD MASCHINENBAU-G. M. B. H. & Co. Ger. 507,728, Sept. 22, 1926. Addn. to 428,843.

"Setting system" for paper machines for reclaiming fiber or white water. CHARLES DUPUIS. U. S. 1,787,341, Dec. 30. Structural features.

Raising the moisture capacity and soaking velocity of animal and vegetable raw materials for paper manufacture. CHEMISCHE FABRIK POTT & Co. and FERDINAND SCHOELLER. Ger. 507,729, May 2, 1925. The materials are treated with sulfonic acids of alkylated aromatic compds., especially of the naphthalene and tetrahydronaphthalene series, alone, mixed or with hydrocarbons, alcs. or ketones.

Resin soaps and emulsions for dressing and finishing paper, etc. CHEMISCHE FABRIK POTT & Co. and FERD. SCHOELLER. Ger. 507,506, May 26, 1925. Natural resin or resinous substances are rendered sol. in water for their removal from, *e. g.*, sawdust or old paper, or for their spreading as glaze, etc., on paper, etc., by treatment with sulfonic acids of polynuclear aromatic hydrocarbons. Isobutyl-β-naphthalenesulfonic acid is mentioned in examples.

Method and apparatus for locally applying colors to wet sheet material (paper). GEBR. PALM, PAPIERFABRIK. Ger. 509,382, Oct. 10, 1924.

Method of making cardboard, etc., from fibrous materials impregnated with asphalt. ALEX. WENDLER. Ger. 509,042, June 13, 1926. Mech. and manipulative features are

24—EXPLOSIVES AND EXPLOSIVES

CHARLES E. MUNROE

Numerical data on the combustion and detonation of gaseous mixtures, powders and explosives. P. LAFFITTE AND H. MURAOUR. *Annual Tables* **7**, 1672–716(1925–26). McGraw-Hill Book Co., N. Y. (1930).—This separate from the Annual Tables of Constants and Numerical Data, Chemical, Physical, Biological and Technological will be of value to all concerned with explosives and explosions. CHARLES E. MUNROE

Instability of colloidal powders. HENRI MURAOUR. *Bull. soc. chim.* **47**, 1230–6(1930).—There are 2 general causes for the decompn. of colloidal powders, thermolysis and hydrolysis; the latter leads to autocatalysis through the formation of HNO_3 from the decompn. products; this HNO_3 induces further decompn. These factors usually are together and produce a composite effect. M. has dealt with each factor independently and traces its effects in the graphs presented. C. E. M.

The sensitiveness of colloidal powders. M. TARLÉ. *Z. ges. Schiess-Sprengstoffw.* **25**, 398–9(1930).—T. investigated the influence of drying on the sensitiveness to impact and the ignition temp. of smokeless powders. Two varieties of powders were tested: strip powder 0.7 mm. thick, with 12.7% N, and flake powder 0.32 mm. thick, with 13.2% N. Samples were dried on watch glasses in an oven at temps. of 30° to 100° for periods up to 72 hrs., cooled in desiccators, weighed and tested. For the impact test, 0.05-g samples, not ground, but of the original thickness, were used, the temp. of test being 18°. Sensitiveness increased with increase in both time and temp. of drying, in about the same ratio as loss of weight, the greatest change occurring in the first 20 hrs. It therefore follows that sensitiveness to impact varies with content of moisture and volatile solvent. Ignition temp. was practically not affected by drying as above described.

C. G. STORM

Determination of potassium perchlorate in explosives containing ammonium nitrate. C. BUNGE. *Chem.-Ztg.* **54**, 915(1930).—Prep. an aq. soln. of 10–15 g. of the explosive, mix it with 20–25 g. of pure quartz powder (which can be platinized), evap. to dryness and ignite. Ext. the residue with water and proceed with the detn. of K by the $HClO_4$ method in the usual manner, taking into consideration any K present as KCl or KNO_3. Sometimes, when too much nitroglycerin is not present, the original powder can be mixed with quartz and ignited directly. W. T. H.

Mercury fulminate. F. H. VAN LEENT. *Chem. Weekblad* **27**, 670–1(1930).—$Hg(ONC)_2$ is considered to be an isocarbonitrile of Hg peroxide. This explains the formation of NaOH in the reaction with $Na_2S_2O_3$, the latter being oxidized by the loosely combined O. An amt. of NaOH can be obtained corresponding to 2O atoms. The remaining part of the fulminate, the isocarbonitrile, functions as a weak acid combining partly with the NaOH formed. The isocarbonitrile can also easily combine with atoms or atom groups and can be titrated with I. E. SCHOTTE

Penthrinit, the new "universal explosive" of Stettbacher. NAOUM. *Z. ges Schiess-Sprengstoffw.* **25**, 442–6(1930).—The conclusions of S. (*C. A.* **24**, 6017) are based on inadequate small-scale tests. Blasting gelatins do not deteriorate to the extent pictured by S. Pb-block compression tests and Trauzl tests with 100-g. samples in cartridges 40 mm. in diam. showed that whereas a 30/70 nitroglycerin-nitropentaerythritol (Penthrinit) mixt. suffered no change in strength after 3.5 month's storage at 30°, com. blasting gelatins contg. 93% nitroglycerin or nitroglycol (or mixt. of same) and 7% nitrocellulose, suffered such slight loss during similar storage that they still gave test results showing strength equivalent to the Penthrinit mixt., and underwent no appreciable loss of sensitiveness Such high-powered explosives have almost negligible practical application. Loss of sensitiveness in gelatin dynamites is of minor importance, since it is customary to use them without extended storage. Pb-block compression tests with 100-g. charges showed that mixts. of 75% tetryl and 25% nitroglycerin, or 70% TNT and 30% nitroglycerin gave practically the same results as 70/30 Penthrinit Sensitiveness tests with the 2-kg. falling wt. gave the following heights of fall: for 65% dynamite 10 cm., Penthrinits with 20–40% nitroglycerin 15–20 cm., picric acid and tetryl 40 cm. Charges of Penthrinit in metal foil invariably detonate on penetration by a rifle bullet (25 m. range), while tetryl or picric acid is frequently not even ignited by similar tests. These tests for sensitiveness do not lead to the conclusion that Penthrinits are suitable for military use. C G. STORM

Composition and properties of certain explosives suitable for the lime, cement and plaster industries. J. DEFORGE. *Rev. materiaux construction trav. publics* 1929, 350–5, 389–94, 440–6.—A general discussion. F. O. ANDEREGG

The influence of radiation in the burning of colloidal powders in a closed vessel. H. MURAOUR *Compt. rend.* **191**, 713–5(1930).—M. has previously shown that at high density of air the curve of pressure-time ($\int pdt$) is practically const., and that in low densities the load of the air decreases considerably. In the hypothesis formulated, that is, of mol. shocks necessary to decomp. the powder, this decrease can only be explained by a variation of temp. of the gaseous layer which heats the powder, or by an addnl. load of energy. By a simple hypothesis this load of energy is considered due to heat radiation of the gas. Studies indicate, and figures are given to show, that the hypothesis of radiation is insufficient to explain the reduction of air observed in the range of low pressure of colloidal powders. ALICE W. EPPERSON

The ignition of detonating gas by electric sparks. A. KOVALSKII. *Z. physik. Chem.*, Abt. B, **11**, 56–8(1930).—The conditions for ignition of the mixt. $2H_2 + O_2$ by elec. sparks were studied. A spark of given strength would cause ignition only when the pressure exceeded a critical value, which could be lowered by strengthening the spark, down to an asymptotic minimum. At 20° this min. critical pressure was 17 mm Hg; at higher temps. it was lower. Quite generally, the critical pressure for ignition by a given spark would decrease with increasing temp. The different pressure-temp. curves meet at 450° and 5 mm., which were min. temp. and optimum pressure for autoignition in the vessel used. L. ONSAGER

Explosives. WALTER FRIEDRICH and KARL FLICK. Ger. 509,118, Oct. 11, 1929. Nitrates of cyclic keto alcs., *e. g.*, tetramethylolcyclohexanone, tetramethylolcyclopentanone or octamethylolcyclohexanedione, or nitrates of the cyclic alcs. obtained by reducing the keto alcs., are used as explosives, alone or mixed with one another or with other explosives. The products are stable when stored at 50°, have a high detonation velocity, and can be poured at a temp. below 100°. The keto alcs. are prepd. by condensing cyclic ketones with CH_2O in the presence of alkalies or alk. earths.

Combustible compositions. ASOCIACIÓN DE PRODUCTORES DE YODO DE CHILE Ger. 509,898, Aug. 19, 1928.

Explosive shell (carrying a drill-hole reamer and external holding threads) for use in mining. STERLING S. LANIER, JR. U. S. 1,787,910, Jan. 6. Structural features.

Pseudo solutions of an explosive or readily inflammable substance. KLEMENS BERGE (Josef Reitstötter, inventor). Ger. 509,792, May 7, 1925. The explosive or inflammable substance to be dispersed is milled with the liquid in a ball mill till the particles are of colloidal size.

Detonators. WILHELM ESCHBACH and GERHARD VON LÖBBECKE Ger. 508,244, Mar. 20, 1929. Reaction of the Cu or brass parts with PbN_6 is avoided by coating them with Cd

Fuses. JOHANNES FRITZSCHE. Ger. 509,350, July 30, 1926. A drying treatment is interposed between the spinning process and the customary impregnation or coating with tar, pitch or gutta-percha.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Artificial silk dyeing. W. WELTZIEN. *Kolloid-Z.* 52, 110–6(1930).—A review. A. FLEISCHER

The dyeing of viscose silk. EMILE DUHEM. *Bull. soc. ind. Rouen* 58, 291–304 (1930).—The principal varieties of artificial silk are mentioned, with reactions for distinguishing them from each other and from natural silk, including combustion and treatment with H_2SO_4, $NHPh_2$, alk. Cu soln. and alk. Ni soln. Comparisons are given of the tensile strengths of natural and artificial silks in the wet and dry states. Tests are given to det. what dyes are suitable for use with viscose. The best dyes for this purpose are those which show the slowest capillary rise in viscose threads, those which give the most ready transfer of color from a dyed skein of viscose to a raw skein in boiling soap soln., and those which, when applied to viscose at various temps., reach their strongest shade at the lower temps. A long list of dyes is given, classified in 2 groups according to their suitability for viscose. Detailed directions are given for dyeing viscose and mixed fibers contg. viscose. I. H. ODELL

Careful choice of equipment essential in dyeing of acetate fabrics. W. GORDON YOUNG. *Textile World* 78, 3031(1930). R. K. WORNER

The liability of dyed wool to mildew with special reference to the resistance resulting from chroming. R. BURGESS. *J. Textile Inst.* 21, T441–52(1930).—Wool dyed by various methods in the lab. was exposed to conditions favorable for the growth of microorganisms. The results of these tests are tabulated and show that the use of chrome in the dye bath imparts to wool a considerable resistance to the development of the mold fungi chiefly responsible for mildew. Results of tests on the effect of various amts. of chrome indicated that ½% chrome, either as CrO_3 or Cr_2O_3, imparts a definite resistance to mold growth, while 1% checks it. The results indicate that the resistance imparted by chrome is due to the impoverishment of the wool as a source of the nutriment required by these organisms. Thorough washing off after dyeing or scouring is beneficial and reduces the liability to mildew. R. K. WORNER

Dyed furs and dermatitis. PERCY BEAN. *Pharm. J.* 125, 640–2(1930); cf. Hazen, *C. A.* 22, 4646.—Fur dyes, methods of dyeing and identification tests for dyes are described. Susceptibility to poisoning varies with different persons. Certain mordants, *e. g.*, Cr compds., are also dangerous. The same class of dyes is used as *hair dyes*. S. WALDBOTT

Belt drier in the dyestuff industry. K. ZEIDENBERG. *J. Chem. Ind.* (Moscow) 6, 1660–5(1929).—For drying *β-naphthol* and *β-naphthylamine* Z. designed a drier of the endless belt type, subjected to the action of a countercurrent of hot air. Preliminary expts. with a small model showed that: (1) The hot air should not be above 90–92°. (2) The air traveling above the belt should be stirred by propellers. (3) At the beginning of the drying the air should be as hot as possible. (4) The velocity of the air

should not be greater than 2.5–3 m./sec. (5) β-Naphthol dried down to 0.7% H_2O absorbed moisture from the atm. to a total of 2% H_2O. (6) The operation is very smooth when there is both a pressure fan at the head and an exhaust fan at the end of the air channel. In a plant constructed on the basis of the information thus obtained, β-naphthol with initial moisture of 40–45%, was dried in 2 hrs. to a moisture content of 0.20–0.64%. β-Naphthylamine dried under similar conditions contained 0.08% H_2O. The drier produces 1870 kg. of dry product in 24 hrs., the initial material having an av. of 35% H_2O, and the final product 0.1 to 0.5%. 75.4 kg. of the dry substance required 77,200 cal./hr., *i. e.*, about 144 kg. steam; the coeff. of useful action was 0.55 for the exptl. model, 0.37 for the actual drying plant. D. K

The use of unoxidizable steel in the dye house. RENATO RIMINI. *Boll. lanier.* **44,** 847–8(1930).—While unoxidizable steel withstands some dyeing solns. well, it has little resistance against H_2SO_4 in concns. above 5%. Steel vats do not absorb dye baths as do wooden vats; hence they give purer shades and are more easily cleaned. Unoxidizable steel is also used to cover dye-house trucks and for the raising chains on the covers of dyeing machines. R. SANSONI

The "handle" of cloth as a measurable quantity. F. T. PIERCE. *J. Textile Inst.* **21,** T377–416(1930).—The "feel" or "handle" of a material is generally measured by such sensations as stiffness or limpness, hardness or softness and roughness or smoothness. Phys. tests are needed which will analyze and reflect the sensations felt and assign numerical values to the measurements. Tests for evaluating stiffness and hardness are described. An instrument, called a "flexometer," is described on which the angle through which a specimen of cloth droops when a definite length is held out over an edge can be measured. By means of a math. formula, this angle is converted into a term called the *bending length* of the material, which is a measure of its draping quality. The stiffer the material, the longer is the bending length. From the "bending length" and the weight of the material, is obtained a quantity called the *flexural rigidity*, which measures the resistance to bending or the stiffness that would be appreciated by the fingers. The measurement of thickness is discussed in detail, since the sensation of this property depends on how much the material is squeezed, and therefore combines both thickness and hardness. In order to compare the stiffness of fabrics of different thicknesses, the "flexural rigidity" may be converted into a quantity called the *bending modulus*, which takes account of thickness. This quantity is in a sense a measure of the intrinsic stiffness of the material. Modifications of the standard procedure for testing bending length of very stiff or very limp materials are described. RUBY K. WORNER

The bleaching of textile fibers. F. HERNANDEZ. *Quim. e ind.* **7,** 201–9(1930). The effects of the quality of water, action of alkalies, of oxidants and of acids on the bleaching of cotton of various kinds, wool, linen, silk and cellulose, are discussed, as are also the action of lime, NaOH and hypochlorites with some practical data. Formulas are given for the liquors used, together with some practical precautions. S. L. B. ETHERTON

The bleaching of plain and color-stripe cotton goods. A. J. HALL. *Chem. Age* (London), *Dyestuffs Monthly Suppl.* **23,** No. 593, 33–4(1930). E. H

Some causes of spots in bleached cotton goods. J. MERRITT MATTHEWS *Cotton* **95,** 123–6(1930).—A case is cited where the occurrence of brown spots on underwear was eliminated by filtering the H_2O. This H_2O supply contained colonies of algin-aceous material non-uniformly distributed. Heating in the kier apparently rendered the substance lifeless and caused the formation of variously sized masses of a slightly agglutinant material which was forced into the cloth by the pressure of the kier liquor. The deposit was not removed by washing or subsequent processing and apparently gave to the cloth the property of absorbing a relatively large amt. of lime, as evidenced by the ash. The brown stains did not appear until the cloth had been stored. They were not accompanied by a weakening of the fiber. It is suggested that the glutinous material undergoes oxidation and drying, resulting in the brown stain. R. K. W

A modified method for determining the tendering of cotton. RUTH EVERETT *J. Home Econ.* **23,** 62–6(1931).—The deterioration of cotton by heat is detd. by its power to reduce Fehling soln. A method developed by Hägglund for detg. Cu_2O has been modified to give accurate results. The cotton is ground in a special non-heating mill, a glass-sintered filter crucible is used for the Cu_2O, molybdophosphoric soln. is substituted for ferric salt to give a more definite end point and a microburet is used when the vol. of $KMnO_4$ soln. required is small. AMY LEVESCONTE

The weight per inch of fibers of different lengths and the numbers of fibers of different lengths per seed, for each of the standard Indian cottons. R. L. N. IYENGAR AND A. J. TURNER. *J. Textile Inst.* **21,** T417–40(1930). R. K. WORNER

Intensive research promises better rayon. A. J. HALL. *Textile World* **78**, 3034–5 (1930).—A brief review of some recent investigations on the effect of raw material on rayon and the importance of time and concn. in the steeping of cellulose in the manuf. of viscose. It is predicted that rayon research will in the near future be directed largely along the lines dealing with micelle size and micelle alignment, since its properties depend largely on these factors. R. K. WORNER

Pure linen damask and the laundry. J. A. MATTHEW. *J. Textile Inst.* **21**, T453–62 (1930).—A discussion is given of the construction of linen damask and the types of damage which may occur to it in the laundry. Some practical suggestions on the finishing of it are given. R. K. WORNER

Proper application of thin-boiling starch in slashing. R. CAMERON WHITNEY. *Textile World* **78**, 3036–7(1930).—Practical. R. K. WORNER

Hindering fermentation in sizing baths. L. RINOLDI. *Boll. laniera* **44**, 390–1 (1930).—In sizing baths of animal glue fermentation is hindered by warming each day to 80° not to boiling, as this reduces the gluing power. Farina and starch baths are best boiled a few min. Where warming is not convenient, there may be used $HgCl_2$, $AgNO_3$, $CuSO_4$, $ZnSO_4$, $ZnCl_2$, Na or K arsenite, phenol, formic or salicylic acid, formol or creosote. One g. $HgCl_2$ or $AgNO_3$ protects against fermentation 1,600,000 g. of sizing bath, while 1 g. Na_2AsO_3 protects only 300 g. Two g. $ZnSO_4$ or $CuSO_4$ per l. of bath is more used. Formol and formic acid are the most useful org. products. Salicylic acid is too weak and too expensive; phenol and the cresols leave an objectionable odor. Formic acid and formol give insol. ppts. with animal glue. R. S.

Dyes. MARCEL BADER, CHARLES SUNDER and DURAND & HUGUENIN SOC. ANON. Swiss 128,243, Aug. 24, 1928. Addn. to 102,540. A stable deriv. of 6-ethoxy-4'-methyl-5-chlorothioindigo in solid form for dyeing and printing is obtained by treating the leuco compd. with SO_3.

Dyes. I. G. FARBENIND. A.-G. Brit. 333,882, March 13, 1929. Mononitro derivs. are obtained by nitrating dibenzopyrenequinones under "milder conditions" than those used as described in Brit. 307,926 (*C. A.* **24**, 243), as by use of a lower temp., shorter time or smaller proportion of nitrating agent for the nitration, and the mononitro deriv. may be reduced to the monoamino compd. Examples are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 334,111, Oct. 22, 1928. Naphthoylene-diarylimidazoles, which may be obtained as described in Brit. 237,294 (*C. A.* **20**, 1527), Brit. 265,...2 (*C. A.* **22**, 322) and Brit. 265,964 (*C. A.* **22**, 503), are converted into other dyes by nitration, which may be followed by reduction. Several examples are given.

Dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 687,316, Dec. 27, 1929. See Brit. 325,5... (*C. A.* **24**, 4164).

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 500,289, April 22, 1928. Blue to gray dyes for wool, silk, cotton and viscose are prepd. by the action of chroming agents on the *o*-hydroxyazo dyes obtained by coupling the diazo compds. from 5-nitro-*o*-aminophenol and its substitution products with *N*-substitution products of 2-amino-5-hydroxynaphthalene-7-sulfonic acid. Numerous examples are given.

Dyes. Soc. anon. pour l'ind. chim. à Bâle. Ger. 509,290, Dec. 9, 1928. Orange dyes for animal fibers are prepd. by the action of chroming agents on the dyes obtained by coupling the diazo compd. from 2-aminophenol-4,6-disulfonic acid with unsulfonated 1-aryl-5-pyrazolines. An example is given.

Dyes. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,210 to 138,226, July 13, 1928. Addns. to 136,649 (*C. A.* **24**, 4400). Chromed dyes are obtained by treating the dye from nitrated 1-diazo-2-hydroxynaphthalene-4-sulfonic acid and 2-amino-5-hydroxynaphthalene-7-sulfonic acid with a chroming agent and subsequently oxidizing the product. The dye colors wool and silk in fast green shades in an alk. bath (138,210). The other patents describe the application of the method to anologous sulfonic acids and to treating the products with Cu- or Ni-yielding agents instead of chroming.

Dyes. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,242, May 12, 1928. Addns. to 136,651 (*C. A.* **24**, 4404). Benzanthrone is oxidized by $Mn_2(SO_4)_3$ in H_2SO_4 to give dihydroxydibenzanthronyl, which is treated with a condensing agent and the product ethylated. The dye colors cotton in Cl-fast grey-blue shades in a blue vat.

Dyes. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,500, Dec. 31, 1927. Addn. to 133,479 (*C. A.* **24**, 505). Pyranthrone is sulfonated with oleum, the product fused with caustic alkali and then ethylated. The monoethoxypyranthrone dye produced colors cotton red from a red vat.

Dyes. Soc. anon. pour l'ind. chim à Bâle. Swiss 138,602, Sept. 17, 1927. A new dye is produced by chroming together the dye from nitrated 1-diazo-2-hydroxynaphthalene-4-sulfonic acid and β-naphthol and the azo dye produced from the above by reducing the NO_2 group. The product colors wool and silk in fast blue-black shades.

Azo dyes. I. G. Farbenind. A.-G. (Richard Stüsser, inventor). Ger. 508,584, July 12, 1925. Cu-contg. azo dyes are prepd. by treating the dye obtained by coupling amines contg. *o*-carboxyl groups with the urea compd. of 2,5-aminonaphthol-7-sulfonic acid or derivs., with Cu-yielding compds. Thus, the Na salt of the dye from 2 mols. *o*-aminobenzoic acid and 1 mol. 5,5′-dihydroxy-2,2′-dinaphthyl-*p*-phenylenediamine-7,7′-disulfonic acid is treated with $CuSO_4$ to give a product which dyes cotton in light fast violet shades. Other examples are given. Cf. *C. A.* **25**, 600.

Azo dyes. I. G. Farbenind. A.-G. (Richard Dereser and Karl Moldaenke, inventors). Ger. 508,586, Dec. 18, 1927. Addn. to 488,535 (*C. A.* **24**, 2303). The method of 488,535 for producing fast, H_2O-insol. dyes is modified by using arylamide derivs. of 2,3-hydroxynaphthoic acid instead of arylides thereof, to couple with the diazo compds. of dihalo-2-aminotoluene which have a halogen atom in the 4-position and which contain at least one atom of Br, I or F. In an example, 4-chloro-5-bromo-2-aminotoluene is diazotized and added to a suspension of 2,3-hydroxynaphthoic acid-4-anisidide in dil. NaOH. Other examples are given. Cf. *C. A.* **25**, 600.

Azo dyes. I. G. Farbenind. A.-G. (Hermann Wagner and Bartholomäus Vossen, inventors). Ger. 508,811, June 20, 1928. Acid yellow monoazo dyes are prepd. by the action of 1 mol. resorcinol or its substitution products or homologs with diazotized 2-chloro-4-amino-1-methylbenzene-6-sulfonic acid. Examples are given. Cf. *C. A.* **25**, 599.

Azo dyes. Soc. anon pour l'ind. chim. à Bâle. Ger. 508,333, Sept. 8, 1928. Complex metalliferous azo dyes are prepd. by the action of suitable metal compds. on a mixt. of different mono- or poly-azo dyes contg. metal-binding groups. The reactions may be effected under various conditions. Like products may be prepd. by treating the metal compd. of an azo dye with another azo dye contg. a metal-binding group. This latter method may be applied on the fiber. Examples are given.

Azo dyes. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,024, May 10, 1928. An azo dye contg. metals is produced by treating with Cu salts the chromed dye obtained by heating nitrated 1-diazo-2-hydroxynaphthalene-4-sulfonic acid with β-naphthol in the presence of AcONa. The dyes color wool and silk in black shades.

Azo dyes. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,203 to 128,209, Oct. 22, 1927. Addns. to 135,220 (*C. A.* **24**, 2610). Equimol. proportions of cyanuric chloride, 1,4-phenylenediamine-3-sulfonic acid, dehydrothiotoluidinesulfonic acid, HNO_2 and $(Ac)_2O$ are allowed to interact so that the first two constituents are diazotized by the HNO_2 and coupled successively with the second two constituents (138,203). The other patents describe the process carried out with other analogous compds. acting with the cyanuric chloride.

Azo dyes. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,227 to 138,234, Sept. 8, 1928. Addns. to 136,650 (*C. A.* **24**, 4401). 1 Mol. 5,5′-dihydroxy-7,7′-disulfo-1,2,2′,1′-dinaphthazine is allowed to react with 2 mols. of diazotized *p*-nitroaniline. The dye colors wool and silk in olive-green shades in acid baths (138,227). The other

patents describe the dyes produced by replacing the diazotized *p*-nitroaniline with other suitable compds.

Azo dyes of the anthraquinone series. BERTRAM MAYER and JACOB WÜRGLER (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,788,314, Jan. 6. Dyes of widely varying color and which are suitable for dyeing cellulose esters and ethers are obtained by diazotizing compds. such as 1,4-, 1,5- or 1,8-aminonitroanthraquinone, 1-amino-2-methyl-4-nitroanthraquinone, 1-amino-4-methylaminoanthraquinone or 1-amino-4-cyclohexylaminoanthraquinone and coupling with components such as resorcinol, *m*-tolylenediamine, 1-naphthylamine, 2-naphthol, diethylaniline and phenylmethylpyrazolone. Several examples are given.

Vat dyes. FELICE BENSA. Ger. 507,829, Aug. 18, 1925. Vat dyes are produced by treating diaryl haloperylene diketones with alkali or alk. earth, in the presence or absence of an org. solvent. Thus, dibenzoyldibromoperylene is lightly boiled with $PhNH_2$ and powd. KOH to give a dye which colors cotton blue, turning to a fast violet in air, in an alk. blue vat. Numerous other examples are given. Cf. *C. A.* **24**, 600.

Vat dyes. FELICE BENSA. Ger. 508,404, Dec. 17, 1927. See U. S. 1,783,137 (*C. A.* **25**, 419).

Vat dyes. LEOPOLD CASSELLA & CO. G. M. B. H. (Richard Herz and Werner Zerweck, inventors). Ger. 507,558, Dec. 11, 1928. Addn. to 458,598. In the prepn. of fast orange vat dyes by halogenating anthanthrone, the anthanthrone is suspended in water and the halogenation is carried out in the presence or absence of a catalyzer, and the halogen acid formed is neutralized. Thus, an aq. paste of anthanthrone is treated with Br at 60–65°. The excess of Br is removed by bisulfite and the ppt. filtered, washed and dried. The HBr may be neutralized by alkali prior to filtration. Cf. *C. A.* **24**, 4167.

Vat dyes. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES DE PRODUITS CHIMIQUES DU NORD RÉUNIES ÉTABLISSEMENTS KUHLMANN. Fr. 688,256, Apr. 3, 1929. A vat dye having a Bordeaux color is obtained by condensing 2,7-dichloroanthraquinone with a product obtained according to Ger. 267,414 from α-naphthoquinone and 1,5-diaminoanthraquinone.

Vat dyes. I. G. FARBENIND. A.-G. (Paul Nawiasky, inventor). Ger. 507,559, Oct. 9, 1926. The NO_2 group of nitrobenzanthrone is replaced by a hydroxyalkyl group and the product treated with alkali. Thus, nitrobenzanthrone is reduced to aminobenzanthrone and treated with H_2SO_4 and HNO_2, cooled and heated with NaOH to form a hydroxy deriv. The product m. 287–288° and is methylated with Me toluenesulfonate and $C_6H_3Cl_3$ to give methoxybenzanthrone, m. 167–168°. The product is a fast green dye.

Vat dyes. I. G. FARBENIND. A.-G. (Karl Wilke, inventor). Ger. 507,560, July 21, 1927. Vat dyes of the benzanthronepyrazoleanthrone series are obtained by oxidizing compds. of the type *Bz*-1-*Py*-1(or 2-2')benzanthronepyrazoleanthrone and alkylating the product. Thus, pure benzanthronepyrazoleanthrone and H_3BO_3 are dissolved in H_2SO_4 and treated with MnO_2 to give a dye which colors cotton in green-blue shades in an alkaline vat. Several other examples are given. Cf. *C. A.* **24**, 2611.

Vat dyes. I. G. FARBENIND. A.-G. (Walter Bruck, inventor). Ger. 507,561, Oct. 28, 1928. Vat dyes of the anthraquinoneacridone series are prepd. by chlorinating the bromo deriv., brominating the chloro deriv. or acting on anthraquinoneacridone with chlorinating and brominating agents simultaneously. Several examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Heinrich Nerescheimer and Willy Eichholz, inventors). Ger. 507,832, Nov. 18, 1928. An orange colored vat dye is produced by condensing 1,4,5,8-naphthalenetetracarboxylic acid anhydride with *o*-phenylenediamine and treating the red dye so produced with an acid oxidizing agent such as $K_2Cr_2O_7$. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Karl Thiess and Friedrich Maennchen, inventors). Ger. 507,833, Feb. 1, 1929. Vat dyes contg. S are obtained by oxidizing 2,5-diarylamino-3-mercapto-1,4-benzoquinone. Thus, 2,5-dianilino-3-mercapto-1,4-benzoquinone and $PhNO_2$ are boiled together for 1 hr. giving a dye which colors wool brown. Several other examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Paul Nawiasky and Emil Krauch, inventors). Ger. 507,935, Apr. 4, 1929. New vat dyes are produced by leading halogen into 2'-anthraquinonyl-*N*-pyrazoleanthrone, or by condensing the latter with such compds. as have at least 1 halogen atom in the mol. Several examples are given. In one, I is added to a soln. of the above compd. in oleum to give a dye which colors cotton greenish yellow from a brown vat. In another, the compd. is condensed with $ClSO_3H$ and treated with I to give a fast yellow dye for cotton.

Vat dyes. I. G. FARBENIND. A.-G. (Walter Albrecht and Fritz Helwert, inventor). Ger. 508,108, Sept. 19, 1928. Vat dyes are prepd. by treating an aq. sludge of pyranthrone with Br or a brominating agent. The reaction mixt. may be kept neutral by gradual addn. of NaOH, etc. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Ernst Honold, inventor). Ger. 508,980, Apr. 12, 1928. Addn. to 435,477. Dihalodibenzanthronyl compds. obtained by the method of 435,477 are treated with acid amides to form the diamino derivs. which are then sapond. Thus, 2,2′-dibenzanthronyl is treated with excess of Br at room temp. to give dibromo-2,2′-dibenzanthronyl, which in turn is converted to the diamino deriv. This is sapond. to give the dye dibenzenesulfamino-2,2′-dibenzanthronyl. Other examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Heinrich Neresheimer, inventor). Ger. 509,422, Feb. 14, 1929. Addn. to 504,016 (*C. A.* **24**, 5507) and 507,344 (*C. A.* 25, 601. Green vat dyes are prepd. by treating halo derivs. of 2-benzanthronyl 1-aminoanthraquinone or its substitution products with acid condensing agents or mild dehydrogenating agents. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Fritz Baumann, inventor). Ger. 509,423, Apr. 10, 1929. For the prepn. of new vat dyes, α-aminoanthrimidecarbazole or its substitution products is reacted upon by anthraquinone-*o*-halocarboxylic acids or their derivs. or substitution products, and the reaction products are converted into the corresponding acridones in known manner. Thus, 4-amino-1,1′-anthrimidecarbazole may be heated at 215° in C_6H_5 with Me 2-bromoanthraquinone-1-carboxylate in the presence of AcOK, MgO and $(AcO)_2Cu$, the isolated reaction product being subjected to acridone ring closure by heating to 100° in H_2SO_4 soln. Detailed examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Walter Mieg and Robert Berliner, inventors). Ger. 509,424, Apr. 23, 1929. Brown to black vat dyes are prepd. by heating aminoanthraquinonylaminocarbazoles contg. at least one acridone ring with anthraquinone derivs. contg. one or more exchangeable halogen atoms. The reaction is effected in a high-boiling solvent in the presence or absence of acid-binding agents and catalysts. Thus, the product obtained by condensing trichloroanthraquinone acridone with 1-benzoylamino-4-aminoanthraquinone, carbazolizing and sapong., may be boiled in $C_{10}H_8$ with 1-chloroanthraquinone in the presence of Na_2CO_3 and powd. Cu. Other examples are given also.

Vat dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 688,029, Jan. 11, 1930. Vat dyes of the dibenzanthrone series are prepd. by treating aminodibenzanthrones with halogenated quinones. Thus, aminodibenzanthrone (prepd. by reduction of nitrodibenzanthrone, the prepn. of which is described in Ger. 402,641) is suspended in $PhNO_2$ and heated with tetrachloroquinone to 190°. The dye obtained contains Cl and dyes cotton in greenish blue shades.

Vat dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 137,954, Jan. 17, 1928. Addn. to 125,480. 2,2′-Dibenzanthronylsulfonic acid, obtained by treating 2,2′-dibenzanthronyl with 12% oleum, is fused with caustic alkali and the product methylated. The resulting dye colors cotton in fast greenish grey shades in a violet vat.

Vat dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 138,316, Sept. 21, 1928. *Bz*-1-*Bz*-1′-Dibenzanthronyl is nitrated to the "mono" stage and the product fused with caustic alkali. The dye gives a wash-fast blue-grey shade to silk.

Vat dyes of the anthraquinone series. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 507,830, Dec. 30, 1928. Aminopyranthrone is condensed with heterocyclic compds. with one or more —C(halogen):N— groups and the product treated with compds. contg. reactive H atoms. The final product may be acylated or alkylated. Thus, monoaminopyranthrone is condensed with cyanuric chloride in the presence of $PhNO_2$ giving a dye which colors cotton brown in an alk. vat. The product is treated with aminoanthraquinone giving a further product which colors cotton in fast violet brown shades. Equimol. proportions of the reacting substances give a dye which colors cotton in Bordeaux red shades. Other examples are given.

Indigo. JUSTIN F. WAIT (to National Aniline & Chemical Co.). U. S. 1,787,069, Dec. 30. The K salt of phenylglycine is fused with a mixt. contg. KOH, NaOH and sodium amide, the fusion mass is dissolved in sufficient water to form a dil. NaOH soln., indigo is pptd., caustic alkali liquor is sepd. from the indigo, the liquor is concd. to a water content of less than 10%, material remaining solid above 230° is removed from the liquor, and the resulting concd. caustic alkali is used for further fusion with sodium amide and with the K salt of phenylglycine.

Dyes of the anthracene series. IVAN GUBELMANN, ROBERT J. GOODRICH and WM. DETTWYLER (to Newport Co.). U. S. 1,787,069, Dec. 30. Several examples are

given of the production of dyes by condensing an anthraquinone halogen-substituted benzacridone which contains a halogen atom in *m*-position to the imino group in the benzene ring, with an aminoanthraquinone compd., and heating the resulting product with a metal chloride such as $AlCl_3$; *e. g.*, from a dichloroacridone, made from 1-chloroanthraquinone-2-carboxylic acid and a 3,4-dichloroaniline compd., by condensing the dichloroacridone further with an α-aminoanthraquinone compd., and heating the resulting product with a metal chloride, which dyes are, in general, dark brown powders contg. combined Cl, insol. in water, alc., alkalies and dil. mineral acids, somewhat sol. in aniline, but readily sol. in concd. H_2SO_4 forming a brown soln. and giving with alk. hydrosulfite a violet vat from which cotton is dyed violet changing to brown on treatment with suitable oxidizing agents.

Indigoid dyes. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,773, Nov. 17, 1927. Addn. to 100,705. Indigoid dyes are produced by condensing an α-ketomonoanil of thionaphthenequinone with 1-methyl-2,3-naphthohydroxythiophene. In the example, thionaphthenequinone *p*-dimethylaminoanil is used.

Indigoid dye. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,774, Nov. 17, 1927. Addn. to 109,483. An indigoid dye is produced by oxidizing 1-methyl-2,3-naphthohydroxythiophene.

Pyridine dyes. Ernst Koenigs. Ger. 507,562, April 10, 1927. Basic pyridine dyes are obtained by treating tert. aromatic bases with pyridine in the presence of powd. Cu and acid chlorides at high temps.

Triarylmethane dyes. Imperial Chemical Industries, Ltd. Ger. 508,499, April 6, 1926. See Brit. 308,906 (*C. A.* **24**, 503).

Triarylmethane dyes. British Dyestuffs Corp., Ltd. Ger. 508,694, Oct. 25, 1928. Addn. to 461,148. See Fr. 662,909 (*C. A.* **24**, 507).

Polymethine dyes. Richard Kuhn and Alfred Winterstein. Swiss 137,958 to 137,960, Feb. 8, 1928. Addns. to 136,391 (*C. A.* **24**, 4404). Dyes of this series are obtained by condensing 1,3,3-trimethyl-2-methyleneindoline (137,958), or *N*-methyl-α-methylhydroquinoline (137,959), or 1,3,3-trimethyl-5,7-dibromo-2-methyleneindoline (137,960), with HCOOH. Examples are given. The dyes color cotton in violet shades.

Polymethine dyes. Richard Kuhn and Alfred Winterstein. Swiss 139,722 to 139,725, Feb. 8, 1928. Addns. to 136,391 (*C. A.* **24**, 4404). Polymethine dyes are obtained by condensing the trichloroacetate or the monochloroacetate or the perchlorate or the formate, of 1,3,3 trimethyl-2-methyleneindoline, with HCOOH. The dyes colored color cotton in violet-red shades.

Polymethine dyes. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,025, May 2, 1927. Polymethine dyes of the indolenine series are obtained by the oxidation of condensation products from 2 mol. of a methylene base (obtained by treating a cyclo-ammonium salt contg. a reactive Me group with alkali) and 1 mol. CH_2O, in non-alk. media. Thus, 1,3,3-trimethyl-2-methyleneindoline is condensed with CH_2O, in 50% alc. and oxidized by Ag_2O and glacial AcOH.

Benzanthrone derivatives. I. G. Farbenind. A.-G. (Georg Kränzlein and Martin Orth, inventors). Ger. 508,109, Feb. 8, 1929. Addn. to 453,280. Hydroxybenzanthrone carboxylic acids are prepd. by treating 2-aroylhydroxynaphthalene-3-carboxylic acids with condensing agents. Thus, the benzoic ester of 2,3-hydroxynaphthoic acid, treated at 140–150° for 6 hrs. with NaCl.$AlCl_3$, yields *4-hydroxybenzanthrone-3-carboxylic acid*, m. 285°, which is a *chromable dye for wool*. The prepn. is described of *4-hydroxy-6-chlorobenzanthrone-3-carboxylic acid*, m. 250–252°.

Dye preparation. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,844, Sept. 16, 1927. The prepn contains a vat dye mixed with urea. A reducing agent may also be added. Examples are given.

Dyes and intermediates of the anthraquinone series. Imperial Chemical Industries, Ltd. and W. W. Tatum. Brit. 333,992, June 18, 1929. Diaminoanthraquinonesulfonic acids, or halogen compds. or dyes derived from them are obtained by converting 1,4- or 1,5-diaminoantnraquinone (or the crude mixt. obtained by nitration and reduction from anthraquinone) into the sulfate salt, baking at a high temp., halogenating (as with Br) and condensing with an arylamine (*p*-toluidine gives a blue acid wool dye).

Dye intermediates. Soc. anon. pour l'ind. chim. à Bâle. Swiss 137,932, to 137,938, Oct. 22, 1927. Addns. to 103,430. New dye intermediates are obtained by the interaction of 1 mol. cyanuric chloride, 1 mol. 1,8-aminonaphthol-4,6-disulfonic acid and 1 mol dehydrothiotoluidinesulfonic acid (137,932). $PhNH_2$ may be used instead of or with the latter constituent (137,933 and 137,934). Different sulfonic

acids of the second constituent are used in the various other patents. Examples are given.

Dye intermediates. Soc. anon. pour l'ind. chim. à Bâle. Swiss 138,190, Sept. 8, 1928. Addn. to 136,040 (*C. A.* **24**, 2614). An azine forming a useful dye intermediate is obtained by esterifying 2-amino-8-hydroxynaphthalene-6-sulfonic acid, oxidizing and sapong.

Intermediates for the coal-tar dye industry. Heinrich von Diesbach. Swiss 139,642 to 139,645, Dec. 12, 1927. Addns. to 136,046 (*C. A.* **24**, 2614). The intermediates are produced by condensing salicylic acid, or resorcinol, or 2-hydroxy-3-naphthoic acid, or 1-hydroxy-2-naphthoic acid, with dimethylolurea. Examples are given.

Formaldehyde condensation products. Soc. anon. pour l'ind. chim. à Bâle. Swiss 137,942 to 137,945, May 19, 1928. Addns. to 136,380 (*C. A.* **24**, 4405). CH_2O is allowed to act on 1,3,3,5-tetramethyl-2-methyleneindoline in the proportions 1:2 (137,942), or on 1,3,3-trimethyl-5-chloro-2-methyleneindoline (137,943), or on 1,3,3-trimethyl-2-methylene-β-naphthindole (137,944), or on 1,3,3-trimethyl-2-methylene-α-naphthindoline (137,945). The products are useful as *dye intermediates*.

Dyeing with chromed dyes. Soc. pour l'ind. chim. à Bâle. Fr. 687,300, Dec. 27, 1928. The fastness of shades obtained with chromed dyes is improved by adding to the dye bath tannin and an aromatic hydroxycarboxylic acid such as salicylic acid or by treating with these ingredients after dyeing.

Dyeing with vat dyes. I. G. Farbenind A.-G. Fr 687,734, Jan. 6, 1930. Vat dyestuffs are fixed on the fiber by means of tervalent Ti compds. Examples are given of the addn. to an indigo bath of the hydrate of Ti_2O_3 prepd. in the presence of a thickening agent such as glue, gum or starch paste and a complex salt of $TiCl_3$ and $HCOONa$. Cf. *C. A.* **24**, 6032.

Aniline-black dyeing. The Calico Printers' Association, Ltd., Louis Amédée Lantz and Ronald Watson. Ger. 508,254, July 21, 1927. See Brit. 279,164 (*C. A.* **22**, 2846).

Dyeing textiles. Durand et Huguenin S. A. Fr. 686,820, Dec. 18, 1929. In the production of fast dyeings and printings by means of esters of a leuconic vat dye, an appropriate oxidizing agent and a substance capable of liberating acid on heating, by steaming on the fiber, is carried out in the presence of an aminosulfonic or aminocarboxylic acid of the aromatic series which acts as a buffer to preserve the dyeing from a superoxidation. Examples are given of the use of the sulfanilate and the diethylaniline-*m*-sulfonate of Na.

Dyeing acetate silk. I. G. Farbenind. A.-G. (Alfred Fischesser, inventor). Ger. 508,562, Jan. 17, 1928. Acetate silk is dyed black with white or colored effects by impregnating the fiber with aminodiphenylamine or similar bases either before or during the treatment with the resist. The diphenyl black may be developed by steaming. Thus, undyed silk is treated with a white resist contg. thickening water, Na sulfoxalate-formaldehyde and AcONa. After printing and drying it is treated with aminodiphenylamine. Another example is given. Cf. *C. A.* **24**, 4171.

Dyeing regenerated cellulose. British Dyestuffs Corp., Ltd., and James Baddiley. Ger. 508,253, May 3, 1927. See Brit. 287,214 (*C. A.* **23**, 528).

Dyeing cotton. I. G. Farbenind. A.-G. (Wilhelm Neelmeier, inventor). Ger. 508,387, May 5, 1926. Cotton is impregnated at ordinary or moderately raised temp. with solns. of the urea derivs. obtained by the action of $COCl_2$ on carboxylated *p*-amino azo or *p*-aminodisazo dyes contg. no OH groups. The impregnated cotton, after drying if desired, is then treated with solns. of Cr salts. Yellow to orange dyeings fast to boiling water are thus produced. Examples are given.

Half-tone effects on textile fibers, etc. I. G. Farbenind. A.-G. (Erich Kern, inventor). Ger. 508,561, Jan. 5, 1928. The fiber is treated with an emulsion of water repelling substance prior to dyeing or printing. Thus, silk fiber is treated with an emulsion of gum arabic with Pr naphthelenesulfonate as the emulsifying agent, prior to dyeing.

Producing variegated colors on fabrics. Durand & Huguenin A.-G. Ger. 508,563, Dec. 14, 1927. Fast variegated colors are produced on fabrics by using enol esters of vat dyes and oxidizing. Several compositions of printing pastes are enumerated in examples.

Coloring threads, etc. Henry Dreyfus. Fr. 687,265, Dec. 26, 1929. A coloring material or a discharge material is applied in an intermittent manner to threads in movement. If the thread contains a cellulose ester it may be sapond., weighted, mordanted, reserved or discharged and then the colors applied.

Cloth printing. Wilhelm Petri. Ger. 508,564, Jan. 30, 1930. A soln. of Johan-

ms bread kernel or similar seed kernels for use in cloth printing, is prepd. by grinding the kernels and forming them into a paste with alc., glycerol or pyridine, before stirring with water. An example is given.

Tinting yarns. HERBERT PLATT, WILLIAM WHITEHEAD and FREDERICK J. WILLIAMS (to Camille Dreyfus). Can. 305,265, Oct. 28, 1930. A tinting fluid for yarns contains a dyestuff, olive oil and a sulfonated olive oil.

Producing patterns on textiles, leather, wood, etc. I. G. FARBENIND. A.-G. (Alfred Eckardt and Kuno Franz, inventors). Ger. 507,743, Oct. 23, 1927. Addn. to 430,946. A mixt. of dye and diluent or dispersion agent is used to produce the pattern or design directly, after soaking the textiles, etc., in cold water if necessary, and the color carrier is removed mechanically.

Apparatus for dyeing tubular textile materials. HANS LOESER. Ger. 506,537, Feb. 12, 1929. Details of the vat.

Apparatus for dyeing, bleaching, mercerizing or other treatments. J. A. BOLTON and S. S. HAMMERSLEY. Brit. 333,888, April 20, 1929. Concn. of the liquor used is kept const. by the action of a hydrometer floating in the liquor, which controls the supply of fresh liquor when needed, through the action of an elec. circuit and valve. Various details of construction are described.

Method and plant for locally dyeing fabrics in a number of colors. MARIUS RATIONIER. Ger. 509,396, Aug. 11, 1927.

Fabric dyeing machine. MASCHINENFABRIK RAPPERSWIL, A.-G. Ger. 509,923, Mar. 1, 1929.

Yarn-dyeing machine. MASCHINENFABRIKEN. TILLM. GERBER SÖHNE & GEBR. WANSLEBEN. Ger. 507,783, June 4, 1929. Details of arrangement.

Apparatus for the irregular dyeing of hanks of yarn, etc. WILLY SCHILDBERG. Ger. 507,990, Oct. 25, 1925. Structural details.

Apparatus for dressing or dyeing hanks of yarn. JOSEF TIMMER. Ger. 507,991, May 7, 1929. Structural details.

Apparatus for treating fabrics with steam after vat dyeing or discharge printing, etc. F. S. CHAPIN and A. H. JACOBY. Brit. 334,069, Aug. 29, 1929. Structural features and details of operation of an "ager" are described.

Preparing and using photographic designs which are projected for purposes such as showing effects of various textile patterns. FRANK TWYMAN and CHARLES F. SMITH (to Adam Hilger, Ltd.). U. S. 1,788,135, Jan. 6. Various details of procedure are described.

Improving textiles, etc. I. G. FARBENIND. A.-G. (Wilhelm Lommel and Heidrich Moenzel, inventors). Ger. 506,987, May 22, 1928. The textiles, etc., are treated with salts of quaternary phosphonium bases. Thus, wool is treated with benzyltriphenylphosphonium chloride. A list of many suitable bases is given.

Softening agents for textile fibers. SOC. ANON. POUR L'IND. CHIM. À SAINT-DENIS. Fr. 688,585, Jan. 21, 1930. Sulfonated products useful as softening agents for textiles are prepd. by treating a fatty acid or fatty acid ester, *e. g.*, stearic acid in the presence of a solvent, with $ClHSO_3$, or with H_2SO_4 while bubbling HCl through the mixt.

Lubricating or softening textile materials. BRITISH CELANESE, LTD. Brit. 333,949, March 17, 1928. Natural or artificial silk, wool, flax, cotton, etc., are treated with di- or poly-hydric alc. compds. such as ethylene glycol, diethylene glycol, propylene glycol, glycerol or ethers such as monoethyl ether of ethylene or diethylene glycol, diethyl ether of diethylene glycol or mixts. of such substances.

Delustering, swelling and softening fabrics of artificial material. ADOLPH W. BUHLMANN. U. S. 1,786,421, Dec. 30. The material is permeated with steam at a pressure of about 15 lb. and temp. of about 100°, then cooled and freed from steam by forcing air through the fabric. App. is described.

Eliminating oil from textiles. THE TWITCHELL PROCESS CO. Fr. 688,514, Jan. 20, 1930. Mineral oils are removed from textile materials by washing them in a bath contg. "mahogany" sulfonates, mixed, if desired, with mud sulfonates.

Textile oils. THE TWITCHELL PROCESS CO. Fr. 688,515, Jan. 20, 1930. A textile oil is composed of (*a*) a mineral oil from which certain components have been eliminated by extn. after a sulfonation with oleum, and (*b*) "mahogany" sulfonates which are produced by this treatment with oleum and which have been sepd. in a relatively complete manner from the mother oil.

Treating animal fibers. DEUTSCHE GOLD-UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Fr. 688,418, Jan. 17, 1930. Animal fibers such as wool are preserved by impregnating them with a soln. of H_2O_2 and drying.

Method and plant for drying textiles, etc., in a series of chambers. HEINRICH BRUGGEMANN. Ger. 509,362, Sept. 28, 1926.

Continuous method and plant for making bands from fibers and hydraulic binders. OSKAR TENNER. Austrian 119,625, May 15, 1930.

Apparatus for treating textile fibers with liquids or gases. SOCIÉTÉ FRANÇAISE DES TEXTILES NÉO-SOIE & NÉO-LAINE. Ger. 509,729, Aug. 7, 1929. App. for treating artificial silk, etc., centrifugally is described.

Apparatus for the wet treatment of textile fibers, especially artificial silk. OSCAR KOHORN & Co. and ALFRED PERL. Ger. 506,977, Aug. 15, 1928. Addn. to 481,247. Details are given.

Wet treatment of spun fibers. AKTIEBOLAGET SVENSKA KONSTSILKE (Oskar Wahlberg, inventor). Ger. 509,728, Aug. 24, 1929. The fibers are wound on a perforated bobbin and treated centrifugally.

Spraying device for the wet treatment of textiles. STICKBORN KUNSTSEIDE A. G. Swiss 138,577, April 26, 1929.

Apparatus for the wet treatment of individual textile pieces. EMILE EYMERIC Ger. 509,921, Mar. 7, 1930.

Apparatus for the wet treatment of fabrics in open width. FRANTIŠEK RUDOLF Ger. 508,478, Jan. 3, 1928.

Machine for the wet treatment of fabrics in open width (foulard type). PAUL BUSCHMANN. Ger. 509,252, Oct. 8, 1929.

Apparatus for the wet treatment of yarn, especially silk. MASCHINENFABRIKEN TILLM. GERBER SÖHNE & GEBR. WANSLEBEN. Ger. 506,978, Apr. 7, 1929. Details of app. for desulfurizing, bleaching, acidifying and scouring.

Wet treatment of cloth rolls. COHOE PROCESSES, INC. Ger. 509,922, Nov. 20, 1926. Details are given.

Alkaline liquids for mercerizing, etc. I. G. FARBENIND. A.-G. Fr. 687,616, Jan. 3, 1930. A high wetting and dispersing power is obtained by addn. of phenols and sulfonic acids or their salts. Org. solvents may be added if desired.

Recovery of mercerizing lye. JOSEF OLIG, JR. & Co. G. M. B. H. Ger. 507,784, and 507,785, Feb. 18, 1927. An app. is described for squeezing and washing the mercerizing lye from treated hanks of yarn, for concn. and use with further hanks.

Bucking process for vegetable fibrous materials. GUSTAV ULLMANN. U. S. 1,787,880, Jan. 6. Fibrous material such as cotton is boiled in a liquor contg. caustic alkalies, metallic hydroxides such as $Ca(OH)_2$, $Ba(OH)_2$, $Al(OH)_3$ or $Fe(OH)_3$ and substances such as sulfonated castor oil adapted to cause the compds. produced from the natural fats and waxes of the fibrous material during boiling to assume a form which can readily be washed from the material.

Bleaching vegetable fibers. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Ger. 507,759, Sept. 23, 1924. Vegetable fiber, especially cotton, is bleached with alk. H_2O_2 at temps. below 50° and in a bath of such weakness that it contains 100 parts of cotton, etc., to 1 part H_2O_2. The bath may contain water glass and the cotton, etc., may be pretreated with weak Cl soln.

Bleaching linen. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER (Hermann Baier, inventor). Ger. 508,386, June 16, 1926. The linen is given an alk. boil and then treated with a series of bleaching baths comprising both oxidizing and reducing baths.

Bleaching feathers, pelts, bristles, etc. ÖSTERREICHISCHE CHEM. WERKE G. M. B. H. Austrian 119,265, Dec. 15, 1929. The materials are treated with gaseous H_2O_2. Suitably, they are warmed in a closed container contg. H_2O_2 soln. not in contact with the materials. In treating pelts, etc., the hide may be protected by pretreatment with fat. Cf. *C. A.* **24**, 3672.

Hypochlorite bleaching compositions. LLOYD T. HOWELLS (to The Electric Smelting and Aluminum Co., Inc.). Can. 305,878, Nov. 18, 1930. A sol. fluosilicate is added to hypochlorite compds. to activate them and produce a bleach for textiles. Where a hard bleach, such as $Ca(ClO)_2$, is used, a sol. fluoride, as KF, is mixed with the fluosilicate to ppt. the Ca producing a soft hypochlorite soln. which is not antagonistic in washing processes. Cf. *C. A.* **25**, 218.

Sizing textile fibers. I. G. FARBENIND. A.-G. Fr. 687,155, Dec. 23, 1929. Textile fibers are sized by treatment with polyvinyl alc. (Hermann and Haehnel, *C. A.* **22**, 214) either alone or with a sulfonated oil and the usual addns. for sizing such as oil, fat, wax, etc.

Sizing textile fibers. E. A. LAMONT. Belg. 367,413, March 31, 1930. The fibers are immersed in a colloidal soln. prepd. by digesting rubber waste in an org. sol-

vent. **Desizing is effected by using an emulsion of an org. rubber solvent in a hot soln. of neutral soap.**

Warp-sizing apparatus. CHARLES B. JOHNSON. U. S. 1,788,196, Jan. 6. Structural features.

Apparatus for sizing threads of artificial silk. VITTORIO VENEGONI. Fr. 687,686, Jan. 4, 1930.

Apparatus for the continuous washing and after-treatment of freshly prepared artificial fiber yarns. I. G. FARBENIND. A.-G. (Otto Weitermann and Hans C. Stuhlmann, inventors). Ger. 508,983, May 12, 1928. Details of construction and arrangement.

Artificial textile fibers. SOIE CHARENTAISE. Fr. 687,485, Mar. 18, 1929. After coagulation the threads from the spinning nozzles are united into a single bundle of parallel strands; this bundle is then submitted in the form of a ribbon to the various finishing operations such as washing, desulfurizing, bleaching, soaping and drying. An app. is described.

Artificial silk. SACHSISCHE MASCHINENFABRIK VORM. RICH. HARTMANN A.-G. Fr. 688,439, Jan. 18, 1930. App. for the washing and final treatments of the silk.

Artificial silk. THE TWITCHELL PROCESS CO. Fr. 688,512, Jan. 20, 1930. Artificial silk fibers of various origins are protected, from the time of their manuf. to the finishing of the cloth, by a layer composed of a chemically inert mineral oil such as paraffin oil and "true mahogany," the sulfonates obtained by treating lubrication oils with oleum.

Treating artificial silk. I. G. FARBENIND. A.-G (Kurt Littmann, inventor). Ger. 508,270, July 11, 1926. Artificial silk is given the appearance of natural silk by treatment in turn, in either order, with a soln. of a tanning agent and a soln. of a metal salt capable of forming with the tanning agent a colorless insol. or difficultly sol. ppt. Specific treatments with tannin soln. and $(AcO)_4Al$ or $SnCl_2$ are described.

Artificial horsehair. WALTER SCHNEIDER. Ger. 509,399, April 5, 1927. Cotton yarn is treated in turn, in either order, with a soln of glutin and a soln. of an Al salt. It is then dry-brushed by mech. means while still damp.

Degumming silk. I. G. FARBENIND. A.-G. (Paul Rabe and Gutav Manthe, inventors). Ger. 508,269, July 15, 1929. Crude silk is degummed by treatment with an acid, e. g., dil. HCl or AcOH, in the presence of sulfonated oils, fats or fatty acids that are not attacked by the acid. Mixed fabrics contg crude silk and acetate silk may be so treated. The treatment may be followed by soaping. Examples are given.

Scouring wool and silk. THE TWITCHELL PROCESS CO. Fr. 688,516, Jan. 20, 1930. Wool or silk is degummed by treating it with an alk. soln. of mineral oil sulfonates, preferably "mahogany" sulfonates. Fr. 688,517 describes a process for scouring wool by the action of an aq. soln. of mineral oil sulfonates and if necessary an alkali of moderate strength.

Felting woolen fabrics. SOC. ANON. DES ÉTABLISSEMENTS RICALENS. Ger. 508,647, May 15, 1929. The fabric is impregnated several times with a suspension of wool fat in soap soln., and after each impregnation a pressure difference is established between the two sides of the fabric so as to force the liquid therethrough in alternate directions. App. is shown.

Apparatus for cleaning and degreasing wool. HAROLD G. HOWELL and THOMAS R. HOWELL. Fr. 688,360, Jan. 16, 1930.

Separating fat from the waste waters of wool washing. KARL IMHOFF, GEORG MARTIN and FRIEDRICH SIERP. Ger. 508,192, Apr. 7, 1926. Colloid-collecting surfaces of the kind described in Brit. 255,833 (*C. A.* **21**, 2949), are used to sep. fat from the waste waters of wool washing, etc.

Wool fat. CARL VON OVERSTRAETEN. Ger. 508,500, Oct. 7, 1926. The ppt. obtained in known manner from wool-washing waste waters is heated with about 1% of sodium carbonate without addn. of water, and allowed to stand at a temp. below 105°. The upper layer, consisting of neutral wool fat, is then decanted and centrifuged.

Mothproofing wool, furs, etc. I. G. FARBENIND. A.-G. (Hermann Stötter, Berthold Wenk and Max Weiler, inventors). Ger. 506,770, Oct. 21, 1927. Wool, furs, etc., are treated with a cold aq. soln. of aromatic, non-halogenated hydroxycarboxylic acids, e. g., hydroxybenzoic acid, or their substitution products.

Waterproofing woolen cloth. V. F. GABBERKORN. Russ. 21,240, Nov. 26, 1927. Woolen cloth is treated for 15–20 min. with a soln. of $Al_2(SO_4)_3$ or alum on a water bath at a temp. not above 70°.

Waterproofing canvas, flax and other heavy sheeting. J. W. MACKENZIE. Brit. 334,020, July 16, 1929. The material is treated with an aq. compn. contg. flour, oil

or fat, rosin and alum, and then allowed to dry. Various details of procedure and compns. are given. NH_3 and a sizing agent such as gum arabic also may be added.

Fireproof fabric. HERBERT PLATT and CAMILLE DREYFUS (to Camille Dreyfus). Can. 307,239, Dec. 30, 1930. A fabric contg. yarn of cellulose acetate is immersed in an aq. soln. contg. approx. 100 g. of H_3PO_4 per l. at 40° for 15 min.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Comparative tests of paints carried out at Chatham dockyard. LEOPOLD H. SAVILE. *Dept. Sci. Ind. Research, Deterioration of Structures in Sea Water, 11th. Rept. Comm. of the Inst. Civil Eng.* 1930, 10–2.—Tests were made to compare some graphite paints with "dockyard" mixed red oxide and "Navy gray" paints. The corrugated iron walls (north and south) of a building were painted and exposed for about 13 years. On the south wall, the paints of graphite, Fe oxide and white lead were in good condition, while one of the gray paints was rated poor and one fair. The former gray was rated good on the north wall; otherwise the results on the 2 walls agreed. Of 2Fe oxide paints, the one giving better results contained a higher % of Fe oxide and no rosin.

I. H. ODELL

Protective coatings for iron and steel. II. Paints and enamels. HENRY N. BASSETT. *Ind. Chemist* 6, 293–6(1930); cf. *C. A.* 24, 4498.—Detailed descriptions are given of the methods in use for the removal of rust and scale, and for enameling, including a typical analysis of a ground coat and a final coat. A discussion of the properties required in the vehicle and of the functions of the pigment in rust-preventing paints, together with useful information on their application, is followed by information gathered from experience in protecting iron and steel from sea water. Varnishes, japans, cellulose lacquers, asphalt, pitch, anti-fouling compns. and methods for providing a cheap temporary protection are discussed.

E. G. R. ARDAGH

Plant and laboratory practice in the manufacture of pigments. L. V. ITZKOVICH AND A. I. GELIKH. *J. Chem. Ind.* (Moscow) 6, 1678–85(1929).—*Lead chrome.*—The chromes of commerce are generally a mixt. of various chromates ranging in compn. between $PbSO_4.2PbCrO_4$ and $2PbSO_4.PbCrO_4$. The following methods of prepg. the pigment were studied: (1) A soln. of $Pb(NO_3)_2$ or suspension of basic lead nitrate was mixed directly with a soln. of $Na_2Cr_2O_7$ and H_2SO_4. (2) A soln. of basic Pb acetate was pptd. with a soln. of dichromate and H_2SO_4. (3) $Pb(NO_3)_2$ was converted by soda into carbonate, and the chrome was then pptd. in the presence of HCl. (4) Basic Pb acetate was pptd. by soda, and the chrome was pptd. in the presence of HCl. (5) Basic Pb acetate was pptd. with CO_2, and the chrome was prepd. in the presence of HCl. (6) Litharge was ground in a mortar with NaCl until the oxychloride was obtained; the latter was then powdered, and the chrome was pptd. in the presence of HCl. (7) Finely powd. litharge was worked up in a beaker with AcOH (10 parts of 80% AcOH to 100 parts of litharge) with gradual addn. of H_2O. From the white "colloidal" litharge obtained paste with water was formed, and the chrome was pptd. in the presence of HCl. The methods starting with insol. salts are to be preferred. The p_H value during, and at the end of the reaction, and the dispersion of the initial insol. salts also have an influence, which is to be investigated further. *Artificial vermilion.*—Known methods of the manuf. of this pigment are reviewed. The plant at Odessa adopted a mixt. of powdered chalk and lithopone as substratum. Trial use of this vermilion for painting agricultural machinery gave satisfactory results. *Ultramarine.*—Calcination of kaolin for use in the manuf. of ultramarine increases its reactivity. For best results calcination should be carried out at about 650–700° for no longer than 1 hr. Of considerably greater importance is the dispersion of the kaolin. In addn. to these, the purity of shade of the ultramarine depends on the observance of a regular series of conditions during the ignition of the ultramarine. The porosity of the crucible material has a cardinal influence.

The white pigments and their technical value. C. P. VAN HOEK. *Verfkroniek* 3, No. 9, 21–4(1930).—A review.

F. DE LEEUW

The use of zinc oxide as a pigment. I. II. PAUL KAMP. *Verfkroniek* 3, No. 8, 20–3, No. 9, 15–9(1930); cf. *C. A.* 24, 4408.—A review.

F. DE LEEUW

Emerald (chrome) green. V. N. SCHULTZ, YU. P. NIKOLSKAYA AND L. F. PENKOVA. *J. Chem. Ind.* (Moscow) 6, 1412–8(1929).—**Emerald green** $(Cr_2O_3)x.(H_2O)y$, **is in general manufd. by fusing** $K_2Cr_2O_7$ **and** H_3BO_3 **at a high temp.** The product

therefore invariably contains boric oxides. The authors studied this process to det. the best and most practical conditions of manuf., as well as the effect of these conditions upon the shade of the product. If the residual B_2O_3 is removed from the green by suitable reagents, the pigment acquires a fresh and bright appearance. The H_2O content of the pigment can be reduced to about 5% without injury to the pigment. From this they conclude that its formula is $3Cr_2O_3.2H_2O$ and that it is formed according to the following equation: $3K_2Cr_2O_7 + 12H_3BO_3 = 3Cr_2O_3.2H_2O + 3K_2B_4O_7 + 4.5\ O_2 + 16H_2O$. For satisfactory results a quantity of H_3BO_3 2 or 3 times the theoretical should be employed. As substitute for H_3BO_3, H_3AsO_3 does not give a sufficiently bright green; H_3PO_4 gives a pigment which is readily sol. in water. D. K.

Color pastes. W. Drostb. *Z. angew. Chem.* **43**, 1002–6(1930).—The significance of color pastes to the painting industry is discussed. The most important properties of linseed oil pastes are viscosity, elasticity and "stringyness." Viscosity is detd. by the work of deformation per unit vol. as obtained by measuring the distance a cone of certain shape falling from a fixed height enters the paste under investigation. The accuracy of the method was shown to be 10%. Elasticity is comparative and is measured by observing the difference in the rate at which the cone used in detg. viscosity enters different pastes. Stringyness depends upon the adhesive properties of the paste and is measured by the length to which a thread of paste is spun out when the cone is withdrawn from the paste. Satisfactory pastes must be smooth and flexible, with a viscosity of 80–180 g. cm. per cc. and a stringyness of 5–20 cm. The av. rate at which the cone sinks into most pastes lies between 0.3 and 2 sec. per cm. though some pastes show a rate of above 5 sec. per cm. High elasticity appears to be an undesirable characteristic. Estn. of the "oil number" resulting from the oil consumption in the conversion of a pigment to a paste shows no correspondence with viscosity, and no conclusion regarding behavior at a higher oil content can be drawn. *Ibid* 1022–5. The workability and character of the paste are detd. essentially by the properties of the combined pigment and linseed oil, though the pigment seems to play the major role. Poor pastes can often be improved by the addn. of some material such as fatty acid, heavy oil or Al stearate. These seem to serve essentially as wetting agents, but the action of each is rather specific, serving to correct some one deficiency of the paste. A new wetting agent has been developed which is general in its action, is required in only small quantities and is much more efficient in the correction of paste deficiencies. The interfacial surface tension between corn, linseed oil and H_2O differs greatly but does not parallel the results of grinding, and the effects produced by the addn. of the wetting agents mentioned cannot be ascribed simply to a change in interfacial surface tension. Rather, these substances appear to serve as protective colloids against the pigment aggregation which is often promoted by the properties of the pigment or the vehicle or both. The especially great influence of the new wetting agent is probably due simultaneously to its action as a protective colloid and its extraordinary ability to decrease interfacial surface tension. C. H. Peet

The story of inks. C. C. Pines. *Am. J. Pharm.* **102**, 677–88(1930).—A popular science talk including a review of the compn. and manuf. of inks. A short bibliography is appended. W. G. Gaessler

Potentiometric determination of saponification number of mixtures of asphalt and drying oils. James V. Demarest and Wm. Rieman, 3rd. *Ind. Eng. Chem., Anal. Ed.* **3**, 403(1931).—The sapon. no. of linseed oil, gilsonite or their mixts. can be very accurately det. by dissolving in anisole, refluxing with alc. KOH, and titrating with standard aq. HCl, a normal calomel electrode and a H electrode of the usual type being used. With mixts. contg. soy-bean oil or Bermudez asphalt the results are less accurate. Blank det. and standardization of the KOH are unnecessary. L. E. Gilson

Kinetics of the baking process of oil varnishes. R. H. Kienle. *Ind. Eng. Chem.* **22**, 1370–3(1930); cf. *C. A.* **24**, 737.—The baking process of a typical oil varnish was studied kinetically; a spectrophotometer was used to measure the degree of bake by the percentage of light of 6600 A. U. reflected by the film. Measurements were made at 275°, 295°, 315° and 335° in air, O and N atms. In each case isotherms of the baking process were obtained by plotting the percentage of reflected light as a function of the time. For each gaseous atm. the percentage of reflected light for the initial and the deteriorated states was also detd. By using these values and analyzing the data of the various isotherms it was found that the baking process follows the expression for a unimol. reaction and satisfactory reaction velocity consts. could be calcd. When the logarithm of the reaction velocity const. was plotted against the reciprocal of the abs. temp. a series of straight lines was obtained. The temp. coeffs. of the baking

process for the different atms. investigated were obtained directly from these curves. Expressed in terms of a 10° temp. difference the coeffs. (k 305°/k 295°) were 1.40, 1.35 and 1.29 for O, air and N, resp. From the reaction velocity consts. and the temp. coeffs. the heats of activation were calcd. by the use of the Arrhenius equation as 22,000, 19,500 and 16,000 cal./g. mol. for O, air and N, resp. Tables and diagrams are given. Several practical applications of the data obtained are discussed. Cf. Genthe, *Z. angew. Chem.* **19**, 2087(1906); *C. A.* **2**, 1690, 2896; **4**, 2882; **15**, 1135, 3559; **16**, 348, 1511; **17**, 3922; **21**, 1192; **24**, 3661. D. Thuesen

Oils, resins, lacquers. Hans Wolff. *Kolloid-Z.* **49**, 210–7(1929).—A review. A. Fleischer

X-ray study of natural and fossil resins. C. Mahadevan. *Indian J. Physics* **5**, 345–57(1930).—X-ray diffraction patterns of natural and fossil resins are essentially alike. A strong halo appears with the intensity max. varying from 14½° to 16°. There is considerable scattering between the direct spot and the inner margin of the halo. The softer resins give larger spacings and as the hardness increases the inter mol. distances become smaller. The resinic acids and resenes obtained from typical resins also give the intense halo within approx. the same range as that for the untreated resins. The common halo is believed to be due to a similar structure of the components in spite of chem. variations. H. W. Walker

The optical rotation of resins. I. Amber. C. Plonait. *Chem. Umschau Fette, Oele, Wachse Harze* **37**, 321–3(1930).—The ext of amber has a strongly positive sp. rotation regardless of the type of solvent used; in a 1-dm. tube the sp. rotation is + 20.5 to + 29.1° in dioxane at 20°. **II. Copal.** C. Plonait and S. Lorbmann. *Ibid* 323–6.—One hundred different copal samples were examd., dissolved in Wolff's solvent (1 benzene, 1 butanol and 2EtOH). Contrary to general belief the different types varied within characteristic limits. Zanzibar copal —25 to —35°, Sierra Leona —28 to —37, Congo —24 to —35, Angola —2 to +12, Venezuela —3 to —21, Brazil —11 to —23, Manilla hard —30 to —48, soft +33 to +55, Borneo +28, Pontianak +33 to 34, Philippine +23 to +31, Netherland India +32 to +37, Batjan +36 to +39, Australian kauri copal —1 to +23°. The sp. rotation is a useful const. in differentiating between different types of copal resins. P. Escher

Modern methods of rosin size manufacture. C. N. Ridley. *Ind. Chemist* **6**, 369–71(1930). F. H.

Paints. Cropp & von Plettenberg. Ger. 508,405, May 15, 1927. Paints for ships' bottoms include 1–10% of Hg powder for the purpose of preventing attachment of barnacles, etc., to the ship. The Hg powder is prepd. by gradually adding an aq. soln. of $HgNO_3$ to a feebly acidified soln. of $FeSO_4$, and decanting and washing the ppt.

Paints. Nicholas J. Schields. Fr. 687,612, Jan. 3, 1930. A paint is composed of a vehicle and oxide of Hg exceeding 25% of the total wt. of the paint, and preferably about 50%. The paint also contains oxide of Fe and minium or other Pb compd.

Paints. De Keyn Frères (Soc. anon.). Fr. 687,252, Dec. 26, 1929. A compn. for use in the paint industry is formed of oxides of Ti and Al (the latter hydrated or not). They may be used as powder or ground with oils or varnishes.

Paints. I. G. Farbenind. A.-G. Fr. 687,086, Dec. 21, 1929. Finely divided

doring materials are mixed in an aq. emulsion of a synthetic resin contg. radicals of a olyhydric alc., a polybasic acid and an unsatd. fatty acid of the drying type. A resin ade from glycerol, linoleic or oleomargaric or ricinoleic acid and phthalic anhydride ay be used.

Coating or painting bituminous materials such as molded battery boxes or flush nks. OLIVER O. RIESER (to Richardson Co.). U. S. 1,788,250, Jan. 6. The surface objected to a preliminary treatment with agents such as $CaOCl_2$, $K_2Cr_2O_7$, nascent O or HNO_3 to render it impervious to the solvent (such as oil of ordinary paint) with ich the coating is applied.

Pigments. RUDOLF BLOCH and CARLO ROSETTI. Ger. 507,834, Jan. 1, 1929. A t fast, luminous, heat-resisting green pigment is prepd. by heating the basic Cu phate $4CuO.P_2O_5.H_2O$ to 640–650° until it reaches the luminous stage.

Pigments. GUANO-WERKE A.-G. VORM. OHLENDORFF'SCHE UND MERCK'SCHE (Walter Hene, inventor). Ger. 507,936, Apr. 4, 1929. $Cr(OH)_3$ contg. weak lkali is heated to glowing in air and the alkali chromate so formed leached out. The oxide is heated to glowing in a reducing atm. to give 97–98% Cr_2O_3 as a finely powd. green pigment.

Green chromium pigment. I. G. FARBENIND. A.-G. (Rudolf Caspari, inventor). Ger. 507,937 May 8, 1926. Chromate soln is heated to 110° with an org. reducing agent optionally under pressure, till an oxide-hydroxide is produced. This is filtered off, washed and heated to glowing to form Cr_2O_3 as a fine blue-green powder. Examples are given.

Titanium pigments. REGINALD H. MONK and LUDVIG FIRING (to Titanium, Ltd.). Can. 307,012, Oct. 21, 1930. Titanates of the alk. earth metals are produced by mixing with pptd. $Ti(OH)_4$ a halide of an alk. earth metal to disperse the $Ti(OH)_4$, mixing with the dispersed hydroxide an alk. earth metal compd. which contains an ion of charge opposite to that of the dispersed hydroxide and calcining the coagulated mass at substantially 840° in the presence of an alk. earth metal compd. Cf. *C. A.* **24**, 6040.

Zinc white. "SMELTING" KOHÁSZATI ÉS FÉMMŰVEK RÉSZV.-TÁRS. Swiss 140,405, May 1, 1929. App. is described for heating a mixt. of metallic material and fuel with air, molten Zn is produced and collected, and for passing a current of O over the Zn vapor to form ZnO. Cf. *C. A.* **24**, 2844.

Iron-free solutions of aluminum salts. LEOPOLDINE DÖRNER NÉE ZOLLMANN VON ZIPSER DORF. Ger. 506,626, Mar. 10, 1925. Al-contg. minerals such as anorthite, labradorite, kaolin, etc., are heated with neutral ferric salt solns. The ppt. is filtered off and an Fe free Al salt soln. Alkali chloride may be added to facilitate the separation. The Fe contg. ppt. is dried and used in *pigments*.

Mill (with roller and contact block) for grinding inks, paints, enamels, etc. ERNEST G. [illegible]. U. S. 1,787,180, Dec. 30. Structural features.

Ink suitable for writing. CHALFANT F. BIVINS. U. S. 1,787,233, Dec. 30. A dry powder suitable for use after mixing with water comprises an admixt. of a suitable color matter together with citric or benzoic acid or both, or salicylic, tartaric or succinic acid, for avoiding undue pptn. of sediment.

Intaglio ink. GEORGE D. KNIGHT (to Emory Winship). Can. 304,857, Oct. 14, 1930. A quick drying ink for use in intaglio printing consists of approx. 22% gilsonite, 51% aromatic hydrocarbon solvent of gilsonite, 22% of water and 5% of glue united to constitute a homogeneous mixt.

Intaglio printing colors. HANNS FLEISCHMANN and OTTO JORDAN (to I. G. Farbenind. A.-G.). U. S. 1,787,239, Dec. 30. Intaglio printing colors are prepd. which comprise a finely dispersed coloring material and a soln., in a volatile org. solvent, of a resinous product formed by the condensation of a urea with an aldehyde, of org. vinyl esters or of dibasic org. acids with polyhydric alcs.

Varnishes. BAKELITE G. M. B. H. (Ernst Elbel and Fritz Seebach, inventors). Ger. 507,998, June 23, 1927. Varnishes comprising a reactive or hardened phenol-aldehyde condensation product and a drying oil are prepd. by grinding the ingredients together in a ball mill or the like.

Varnishes. BAKELITE CORP. Fr. 688,303, Jan. 15, 1930. An oleoresinous varnish resistant to water is made by incorporating chlorinated naphthalene in a mixt. of a resinous substance and a fatty oil and afterward adding suitable varnish solvents. A mixt. of rosin and tetra-chloronaphthalene is mentioned as suitable. In an example, tung oil 70, Cellosol 120, CH_3O 120, colophony 50, $(CH_3)_6N_4$ 1 and chlorinated naphthalene 90 and xylol 250 parts are melted together and dehydrated. Solvents such as a mixt. of toluene are added. Other examples are given.

Varnishes, etc. I. G. FARBENIND. A.-G. Fr. 687,119, Dec. 23, 1929. Varnishes,

mastics and like coverings are made from cellulose ethers, resinous condensation products sol. or swelling strongly in benzene hydrocarbons, prepd. from polybasic acids and derivs. of polyhydric alcs. which contain at least one free OH group, and solvents with or without other substances. Thus ethylcellulose and a condensation product of phthalic acid and the glyceride of linoleic acid contg. unesterified groups are dissolved in a mixt. of C_6H_6, toluene and alc. The product is a valuable coating for wood. Other examples are given. Cf. *C. A.* **24**, 6040.

Drying varnish films such as those on fibrous insulating material. PAUL B. COCHRAN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,786,824, Dec. 30. Fibrous material such as silk or cotton insulation is preheated in ozonized air to strengthen the material and sat. it with ozone, there is then applied to it an insulating varnish contg. asphalt, a vegetable drying oil and a volatile thinner, and heating is continued at an elevated temp. to expedite oxidation of the oil and drying of the varnish assisted by the ozonized air and ozonized fibers.

Driers for varnishes, etc. GEBRÜDER BORCHERS A.-G. Fr. 688,306, Jan. 15, 1930. Driers having a high metal content are prepd. by replacing the H of the OH or COOH groups of mono- or poly-hydroxy fatty acids contg. one or more COOH groups or of the glycerol esters of these acids by metals such as Al, Pb, Zn, Co, Cu, Mn and Bi. Examples are given.

Drying-oil composition. JAMES E. BOOGE (to Canadian Industries, Ltd.). Can. 305,163, Oct. 28, 1930. To make a permanent mixt. of nitrocellulose and a drying oil (linseed, China wood or perilla) the hot oil is blown with air, which results in a drop in the I no. of the oil, accompanied by an increase in the viscosity that renders the oil completely miscible with pyroxylin jelly, and then the blown oil is mixed with nitrocellulose. This compn. is used in the manuf. of *artificial leather, films*, etc.

Lacquer. ROBERT T. HUCKS (to Canadian Industries, Ltd.). Can. 305,160, Oct. 28, 1930. Colloided pyroxylin contg. dibutyl phthalate is mixed with a pulp pigment contg. a substantial quantity of water, the mixt. is stirred until the water seps. and the sepd. water is removed. Prior to, or during mixing it is preferable to add a small amt. of an active pyroxylin solvent which is also a water repellent and hastens the sepn. of the H_2O.

Lacs. ALLGEMEINE ELEKTRIZITÄTS-GES. Ger. 509,538, May 26, 1927. Addn. to 410,600. In making the lac described in 410,600, from resin, asphalt, wood oil, linseed oil, etc., 1–10 parts of NH_3 are used as the emulsifying agent in the cold.

Lacs. LOTHAR BARENSFELD. Ger. 508,556, May 9, 1928. A wrinkled effect is produced by spraying a solvent liquid over a smooth-dried wood-oil lac. Thus, a smooth-dried coating of a lac contg. collodion, wood oil, Cu resinate, AcOBu and toluene is sprayed with a mixt. of AcOBu, AcOEt and toluene.

Colored nitrocellulose lacs. I. G. FARBENIND. A.-G. (Erich Richter, inventor). Ger. 509,539, Feb. 2, 1926. See Brit. 291,539 (*C. A.* **23**, 1293).

Coating lac of hardened phenolic resin. BAKELITE CORPORATION. Ger. 508,814, June 5, 1926. See *C. A.* **22**, 2476 (Brit. 276,417).

Coating materials. I. G. FARBENIND. A.-G. Fr. 688,315, Jan. 16, 1930. A compn. for the production of coatings on porous materials consists of emulsions of solns. of cellulose derivs. in aq. solns. of org. colloids sol. in water, capable of forming films, in the presence of supplying agents. Thus, a nitrocellulose varnish is emulsified in a soln. of methylcellulose in water and dibutyl phthalate is added. Other examples are given.

Coating composition. CHESTER G. GAUERKE (to Canadian Industries, Ltd.). Can. 305,654, Nov. 11, 1930. A coating compn. contains run β-eleostearin, a modified glyptal resin, high-boiling gasoline and cobalt drier.

Coating composition. VICTOR H. TURKINGTON and WILLIAM H. BUTLER (to Bakelite Corp.). Can. 306,936, Dec. 23, 1930. A coating compn. includes a resinous reaction product of a phenol having a mol. wt. of about 122 or higher with a methylene-contg. agent and a fatty acid.

Coatings for flame-retarding coverings. HARRY N. BOCKUS (to The Solar Compounds Corp.). Can. 305,733, Nov. 11, 1930. A coating comprises 6 lb. of an alc.-sol. gum dissolved in 1 gal. of thinner, a plasticizer 3% by wt. of said soln., and a colored pigment. Cf. *C. A.* **24**, 4127.

Linoxyn. RUDOLF KÜRTH. Ger. 508,812, June 22, 1928. Lynoxyn cloth is prepd. by soaking coarsely woven fabric with linseed oil and oxidizing. Fabric made wholly or partly of artificial silk may be used.

Linoxyn. RUDOLF KÜRTH. Ger. 508,813, July 14, 1928. Bands of cellulose, paper, cellulose yarn or paper yarn are punched, soaked and oxidized. The surface

may have a wave-like form and the oxidizing air may be artificially supplied to the oxidizing chamber.

Linoleum. EDMUND CLAXTON (to Armstrong Cork Co.). Can. 305,126, Oct. 28, 1930. A mixt. of linseed oil and an anticoagulant resin is oxidized to a linoleum cement. A linoleum mix contg. this cement and a coagulant is then prepd.

Resins. ALEX STIEL. Fr. 688,329, Jan. 16, 1930. Insol. or difficultly sol. natural resins are transformed into easily sol. resins by treating them in a finely divided state with O or oxygenated gases. The treatment may be carried out in moist air and with the aid of chem. active light.

Rosin. ROBERT C. PALMER (to Newport Co.). U. S. 1,787,281, Dec. 30. Rosin in solid form substantially free from cryst. abietic acid is prepd. by adding to rosin while in the liquid phase an amt. of caustic alkali sufficient to neutralize 2.5-6% of the abietic acid content of the rosin under treatment (thus forming a relatively small quantity of alkali metal abietate) and allowing the treated rosin to solidify.

Mastic. CARNITT ROSTSCHUTZ- UND FARBSTOFF GES. M. B. H. Fr. 688,482, Jan. 20, 1930. A mastic which may be applied as a coating or by pulverization is composed of ground slags such as Fe slag and a support or binding material.

Resinous compositions. BAKELITE CORP. Fr. 686,772, Dec. 17, 1929. A fibrous resinous compn. useful as *an insulator* is composed of ligneous fibers rich in α-cellulose and a potentially reactive resinoid, such as a PhOH-CH_2O condensation product in the potentially reactive state. Cf. *C. A.* **24**, 1996.

Condensation products from aldols and urea. I. G. FARBENIND. A.-G. Ger. 500,753, Sept. 16, 1926. Water-sol. resins having emulsifying and wetting properties are prepd. by heating aldols with urea, *e. g.*, at 110–120°. An example is given.

Condensation products of urea and alcohols or ketones. I. G. FARBENIND. A.-G. (Max Paquin, inventor). Ger. 506,963, Oct. 5, 1926. Oily or resinous products are obtained by heating urea or derivs. with excess of alcs. or ketones, optionally under pressure and with catalyzers. In an example, urea is heated with AcH and glycerol to 150° for 1 hr., to produce a viscous oil. Many other examples are given.

Condensation products of urea and alcohols or ketones. I. G. FARBENIND. A.-G. (Max Paquin inventor). Ger. 508,795, Nov. 7, 1926 and 508,796, Mar. 15, 1927. Addn. to 506,963 (preceding abstr.). In producing synthetic resins and oils by the method of 506,963, the starting materials are allowed to react in the presence of strong mineral acids (508,795), or in the presence of amino compds. other than urea (*e. g.*, toluene sulfamide) (508,796). In the former case, the reaction takes place without external addn. of heat. Examples are given.

Laminated products bonded with synthetic resins. JOHN M. TAYLOR, CLIFTON N. JACOBS and ROBERT R. TITUS (to Continental-Diamond Fibre Co.). U. S. 1,787,404, Dec. 30. A plurality of strips of material such as paper or cloth are treated with a synthetic resin in its sol. stage, the strips are dried, superposed one upon another and each strip, prior to its application to the previously assembled strips, is heated to melt the resin and is then immediately rolled in contact with the previously assembled strips.

Synthetic resins. CARLETON ELLIS. U. S. 1,787,618, Jan. 6. A material contg. a S chloride resin derived from 10 parts of a phenolic compd. with at least 15 parts of S chloride is incorporated with a small proportion of a formaldehyde material, and the mixt. is heated substantially to raise the softening point of the material without rendering the resin infusible.

Synthetic resin. CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE G. M. B. H. (Wolfgang Haehnel and Willy O. Herrmann, inventors). Ger. 507,962, Apr. 30, 1927. Polyvinyl alc. is condensed with CH_2O or paraformaldehyde in such amts. that the resinous product contains both components. Examples are given.

Synthetic resins. I. G. FARBENIND. A.-G. (Otto Schmidt and Karl Seydel, inventors). Ger. 508,994, Mar. 24, 1926. Addn. to 420,414. Resins manufactured by condensing cyclic ketones are worked with natural or artificial rubber-like products in the presence or absence of other materials such as cellulose. Examples are given.

Synthetic resins. I. G. FARBENIND. A.-G. Fr. 688,185, Jan. 14, 1930. Condensation products prepd. by condensing urea or its derivs. with CH_2O, its polymers or derivs. in org. solvents, are sepd. from the solvents by a steam distn., if necessary under vacuum and with superheated steam. Examples are given.

Synthetic resin compositions. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 687,801, Jan. 9, 1930. Resins are made by condensing a polyhydric alc. with a polybasic acid in the presence of one or more mono-carboxylic acids, a drying oil being incorporated at any stage. Thus, glycerol, phthalic anhydride and oleic acid are heated to 200–250° and linseed oil is added to form a clear brown resin. The oleic acid may

be replaced by linseed oil acids and the linseed oil by China wood oil. Cf. *C. A.* 24, 740, 4648.

Synthetic resins. LÉON ARNAUD. Fr. 688,269, April 5, 1929. Synthetic resins are prepd. by condensing CH_2O and urea in the presence of glucides (levulose, glucose, saccharose, dextrin, etc.), with oxides, hydroxides or basic salts of heavy metals as catalysts; the mass is brought to a degree of neutralization between acidity to tournesol and neutrality to methyl orange. This state of neutralization is obtained by the addn. of NH_4 salts or salts of aliphatic or aromatic amines.

Heavy metal salts of monoalkyl phthalates. COMMERCIAL SOLVENTS CORPORATION. Ger. 509,937, Apr. 1, 1926. These are prepd. from solns. of alkali metal monoalkyl phthalates and solns. of salts of Zn, Fe, Pb, Cu, Ni, Cr, Co, Cd and Mn. The example describes the prepn. of Zn butylphthalate from Na butylphthalate and ZnCl. The products are *synthetic resins*.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL.

The pyrolysis of vegetable oils of high acetyl number. RAYMOND DELABY AND RAYMOND CHARONNAT. *Compt. rend.* 191, 1011-2(1930).—In order to det. whether the com. grape-seed oil contains ricinoleic acid its thermal decompn. under reduced pressure was studied. Under conditions in which the Na soap of ricin yielded sebacic acid, methylhexylcarbinol, and the corresponding ketone, the grape-seed oil gave only a no significant alc. fraction and an oily acid phthalate. Grape seed oil, therefore, does not contain ricinoleic acid or other ethylene acid alc. capable of breaking down into a satd. aldehyde and unsatd. acid. RACHEL BROWN

Investigations on castor oil. EMILE ANDRÉ AND CL. BESSÉ. *Ann. combustibles liquides* 5, 463-80(1930); cf. *C. A.* 24, 2908.—A complete chem. and phys. examn. is made of various grades of castor oil. The various tests for adulteration are discussed. The H_2SO_4 test is not reliable. The petr. ether test was examd. for mixts. with 1 to 20% of other oils; only in the latter case are reliable results obtained. E. SCHERUBEL

The oil-palm industry. S. M. GILBERT. *Trop. Agr.* (Trinidad) 7, 204-9(1930). The oil content of the fruit of the oil palm is about 20% by wt. One variety from S. Nigeria contains 55% oil. The av. tree produces 20 lb. of fruit annually which by native methods of extn. yields only about 2 lb. of oil. Methods of production of fruit and extn. of oil are discussed in detail. In Nigeria oil is produced by 2 different primitive hand methods known as the hard-oil and soft-oil processes. Soft oil consists chiefly of triglycerides palmitates. The hard oil is less desirable because it contains free fatty acids but since no premium is paid for soft oil in the export market only hard oil is exported. The chief method of extn. in the Belgian Congo is the centrifugal process and in Sumatra it is the hydraulic-press method. A. L. MEHRING

Determination of trimethylene glycol in glycerol. K. CAZAFURA. *Seifensieder-Ztg.* 57, 789-91(1930).—This is a crit. discussion of the detn. of trimethylene glycol in glycerol by Rojahn's method and Fachini-Somazzi's method (*C. A.* 18, 2858), and a suggestion of some changes and adoption of Bosart-Snoddy's sp. gr. table for glycerol (*C. A.* 21, 1907). The F.-S. method for trimethylene glycol depends upon the detn. of total O_2 consumption of glycerol + trimethylene glycol with $K_2Cr_2O_7$ and upon the gravimetric detn. of CO_2 evolved, from which data the % of each can be calcd. A slight error in titration or CO_2 wt. causes a large error in the final results. P. J. CARR

Detection of carnauba wax in beeswax. LLOYD R. WATSON. *Chemist Analyst* 20, No. 1, 4-9(1931). See *C. A.* 24, 2908. W. H. H.

Potentiometric determination of saponification number of mixtures of asphalt and drying oils (DEMAREST, RIEMAN) 26. Some errors in analytical bromination (BLICKWALTER, WAGNER) 7. Siam Government Laboratory, 4th report [oils] (MARCH) 17. Separating fat from the waste waters of wool washing (Ger. pat. 508,192) 25. Hydrogenating oils, etc. (Fr. pat. 687,204) 22. N compounds [soaps] (Fr. pat. 687,2[illegible]) 18. Apparatus with superposed evaporating trays suitable for distillation of oils and liquid solvents (U. S. pat. 1,787,309) 1. Apparatus for determining specific gravity of oils, etc. (U. S. pat. 1,787,132) 1. Decomposition of salts of mineral-oil acids and of fatty and tar acids (Russ. pat. 54,955) 22.

McGOWAN, ELLEN BEERS: ***A Comparative Study of Detergents, with Special Reference to the Teaching of the Subject.*** *New York: Columbia Univ.* 125 pp.

Fatty acids. HANS P. KAUFMANN. Fr. 687,233, Dec. 26, 1929. Satd. fatty acid are prepd. from fats, or fats are enriched in fatty acids by uniting in a single operation catalytic hydrogenation and hydrolytic decompn. Several examples are given.

Fatty acids from oxidation of paraffin, etc. I. G. FARBENIND. A.-G. Brit. 333,904, March 14, 1929. For effecting isolation of fatty acids from crude oxidation products such as those of paraffin, montan wax or beeswax, the products are treated, at room temp. or slightly higher temp., with an alkali (such as anhyd. Na_2CO_3) in quantity sufficient to neutralize exactly the free acids in the material; the neutralized mass is preferably dried, and, after removing unsaponifiable materials and esters by extn. with a solvent such as benzine, the resulting pure salts are decompd. with an inorg. acid. Details of treatment are described.

Fatty acid derivatives containing nitrogen. I. G. FARBENIND. A.-G. Fr. 687,865, Jan. 8, 1930. Derivs. of higher fatty acids are made at high temps. with or without catalysts and, if necessary, under pressure by the reaction of solns. of NH_3 in org. solvents such as alcs. on halogen derivs. of satd. or unsatd. higher fatty or hydroxy fatty acids. The products have the property of *soaps*. Examples are given of the treatment of hexachlororicinoleic acid, hexachlorostearic acid, chlorolinoleic acid and the ethyl ester of tetrachlorooleic acid.

Splitting fatty acid esters. H. T. BÖHME A.-G. Brit. 334,022, Oct. 17, 1929. Esters such as fats or oils are hydrolyzed by heating with water in the presence of a product obtained by the sulfonation of a mixt. of an alc. such as "olein alc." and an aromatic hydrocarbon such as naphthalene.

Purifying oils and fats. I. G FARBENIND. A.-G. Fr. 688,370, Jan. 17, 1930. Impurities such as soaps, resinous, mucilaginous or albuminous substances are sepd. from oils or fats by adding org. substances practically insol. in oils or fats (which adhere to the impurities and which are capable of dissolving them) in such small quantities that the impurities are sepd. without being dissolved, or by emulsifying the oils or fats with such small quantities of liquids which do not mix with them, that the added liquids form the internal phase in the resulting emulsion. Thus, 100 parts of cottonseed oil is treated in a turbo-mixer with 2 parts of distd. water and the resulting emulsion is centrifuged. Soy-bean oil (100 parts) is treated with formamide (2 parts) and the resulting emulsion is filtered. Other examples are given.

Apparatus for extracting oils and fats. PAUL PÁRODI. Fr. 687,710, Jan. 6, 1930.

Apparatus for extracting oils, fats, etc. VOLKMAR HÄNIG & Co. Ger. 508,313, Aug. 22, 1926. A construction of grating or sieve is described.

Glycerophosphates. J. D. RIEDEL-E. DE HAËN A.-G. Ger. 507,794, July 15, 1927. Addn. to 421,216. Soy-bean ext. or lecithin-free soy mucus is sapond. with aq.-alc. alkali and the resulting glycerophosphates sepd. from the soap, bases and glycerol, by alc. The impurities insol. in alc. are removed by water. Examples are given.

Cholesterol. GÜNTHER ADAM. Ger. 508,407, Jan. 10, 1930. Cholesterol is sepd. from the saponn. products of wool fat by treating these with a soap prepd. from coconut oil and/or palm-nut oil, dilg. the mixt., and allowing it to stand in the warm after satg. it with salt. Addnl. details are given.

Basic products. I. G. FARBENIND. A.-G. Fr. 687,224, Dec. 24, 1929. Fatty acids, or their esters, chlorides or amides are condensed with amino alcs. contg. at least 2 amino groups one of which is a tertiary group. Thus, oleic acid or its ethyl ester is heated to 220° with diethylamino-β-hydroxypropylamine, giving a viscous oil. Other examples are given. The products are auxiliary agents in the manuf. of *rubber*, and thickening agents for the prepn. of *cosmetics*, etc. Cf. *C. A.* **24**, 2244.

Rendering waxes, soaps, etc., electrically conductive. THE GRAMOPHONE CO., LTD. Ger. 508,206, Mar. 1, 1928. See Brit. 290,406 (*C. A.* **23**, 778).

Detergent. HOMER LANDON (to Joseph Lewis). Can. 305,022, Oct. 21, 1930. To a soap (preferably made by using both soda and potash lye) are added Na_3PO_4 and an abrasive such as fine granular silica sand.

28—SUGAR, STARCH AND GUMS

J. K. DALE

Identifying liquids **such as lubricating oils (U. S. pat. 1,787,995) 22. Organic** acids by fermentation **(Can. pat. 306,081) 16.**

WOMACKA, OSKAR: **Betriebskontrolle der Zuckerfabrikation. II Teil: Chemische**

technische Rechnungen. 3rd ed., enlarged and improved. **Magdeburg: Schallehn & Wollbrück.** Reviewed in *Intern. Sugar J.* **32,** 635(1930).

Sugar. BERTHOLD BLOCK. Ger. 509,580, Sept. 5, 1928. Sugar sap is satd. by leading the sap residues back through the sap till satn. is reached. The app. is described.

Sugar. SOC. ANON. DES ÉTABLISSEMENTS A. OLIER. Ger. 507,884, Mar. 2, 1928 An automatic continuously acting device is described for treating solid sugar-contg. materials with extg. liquid.

Sugar extraction. KARL PHILIPP. Fr. 688,013, Jan. 10, 1930. See Ger. 502,881 (*C. A.* **24,** 5533).

Apparatus for treating sugar juices with lime. WALTHER SCHRADER. Ger 508,231, Mar. 2, 1928.

Purifying saccharine liquids such as sugar juices, sirups or molasses. LEONARD WICKENDEN and JOHN J. NAUGLE (Wickenden to Naugle). U. S. 1,787,502, Jan. 6. Material contg. 2 or more types of impurities is treated with subdivided carbonaceous adsorbent of varied degrees of fineness, one portion of which adsorbs one type of the impurities and another portion of which adsorbs another type of the impurities. An arrangement of app and numerous details of procedure are described.

Recovery of sugar from sugar-house and refinery scums. D. TEATINI. Belg. 367,849, March 31, 1930. The scums are worked up with a liquid so as to obtain a "milk" of predetd. d., which is then treated with CO_2 or SO_2 so as to reduce the alky. to the point required for max. liberation of sugar. The mixt. is then filtered and the filter cake washed to an extent depending on the degree of recovery desired.

Purifying sugar-house and refinery juices. D. TEATINI. Belg. 367,847, March 31, 1930. The raw juices are treated with an amt of SO_2, preferably in liquid form, which is detd. in each case. This treatment is preceded by an alkalinization depending on the nature of the raw juice to be treated, and followed by addn. of a small quantity of CaO, or its equiv., which is subsequently pptd. with CO_2 or the like. Belg. 367,848 provides for the elimination of the usual carbonation treatment. The previously alkalinized raw juice is treated at suitable temp. with a predetd. quantity of SO_2, as liquid or gas, so as to cause flocculation in the liquid, which is subsequently clarified.

Multiple-effect crystallization of sugar. JOSHUA R. RAY and THOMAS RAY. U. S. 1,785,530, Dec. 16. An evapg. pan is partially filled with liquor, and after partial evapn., more of the liquor is slowly fed to the evapg. pan; a cut strike is then made into a plurality of assocd. evapg. pans of the multiple effect, and the second-mentioned pans are fed with fresh liquor. Various details of app. are described.

Rotary-drum crystallization apparatus for sugar, etc. N. V. CONSTRUCTIE ATELIER DER VORSTENLANDEN. Ger. 507,115, May 15, 1929.

Rotary sugar press. MASCHINENFABRIK GREVENBROICH A.-G. Ger. 509,581, Dec. 9, 1928.

Machine for dressing the bases of sugar loaves. INGENIEUR- UND INDUSTRIEBÜRO G. M. B. H. Ger. 509,909, Mar. 30, 1928.

Levulose from inulin. SCHERING-KAHLBAUM A.-G. (Friedrich Medicius, inventor). Ger. 507,612, June 16, 1926. Com. inulin is treated with warm water and the water then removed by a centrifuge. The residue is treated with volatile org. acids to form fruit sugar. The example mentions HCOOH.

Treating massecuite. JULIEN BERGE (to RAFFINERIE TIRLEMONTOISE SOC. ANON.). U. S. 1,784,982, Dec. 16. For increasing the yield of sugar crystals from any kind of massecuite, it is cooled to pasty condition, followed by sepn. of the mass into sugar crystals and sirup by centrifuging, employing a centrifugal force considerably more than 800 times the wt. of the mass to be sepd.

Evaporators for the manufacture of gums, gelatins, etc. EMILE A. REBIÈRE. Fr. 687,780, Jan. 7, 1930.

Starch. CHEM. FAB. MAHLER & SUPF A.-G. Ger. 508,160, Nov. 16, 1921. A product that swells in cold water is prepd. by grinding starch or amylaceous materials with dry caustic alkali.

Starch. W. H. UHLAND G. M. B. H. Ger. 508,149, April 4, 1926. A method and app. are described for washing concentrates obtained from crude starch milk.

Cold-water starch. HENKEL & CIE. (Max Jacobi, inventor). Ger. 508,786, May 16, 1925. The moistened starch is intimately ground with caustic alkali below the paste-forming temp., dried and re-ground.

29—LEATHER AND GLUE

ALLEN ROGERS

Adsorption of sulfuric acid by leather. JOHN BEEK, JR. *Ind. Eng. Chem.* **22**, 1373–8; *Bur. Standards J. Research* **5**, 1109–21(1930).—Samples of vegetable-tanned steer hide were placed in 300-cc. portions of soln. contg. 0–12% H_2SO_4. Expt. showed that equil. was reached in 2 hrs. The leather was drained and solns. poured off were weighed and analyzed. The H_2SO_4 content of leather + residual soln. was detd. The H_2SO_4 content of residual soln. was calcd. and deducted, and the remainder taken as adsorbed H_2SO_4. Corrections were made for the S content of leather and for the sol. matter leached from the leather. With increasing H_2SO_4 concn., H_2SO_4 adsorbed (millimoles per g. of insol. leather) increased from 0.07 when H_2SO_4 = 0.0022 *M* to about 0.2 when H_2SO_4 = 0.04 *M*, and is thereafter const. until H_2SO_4 = 0.48 *M*. Further increase in concn. results in decreased adsorption. Application of the Gibbs equation for adsorption due to change in surface tension showed that adsorption due to this cause would be neg. over the whole molality range. It is suggested that adsorption up to H_2SO_4 = 0.4 *M* is due chiefly to chem. combination, and that the decreasing adsorption at higher molalities is due to surface-tension effects. Expressions are derived for acid chemically combined, based on the mass law, and acid adsorbed due to surface tension effects, based on the Gibbs equation, that fit the author's exptl. data fairly well. This equation also fits data of Kubelka and Wagner for HCl adsorbed by hide powder. The equiv. wt. as a base of the steer hide leather used was 4.3 × 10^3. The sp. surface of the leather was of the order of magnitude of 10^7 sq. cm. per g. R. G. HENRICH

Solutions of gallic acid and tannin (STEENHUISEN) **2.** Coating materials [artificial leather] (Fr. pat. 687,597) **18.** Cellulose esters [artificial leather] (Fr. pat. 687,996) **23.** Bleaching feathers, pelts, bristles, etc. (Austrian pat. 119,265) **25.** Producing patterns on leather, etc. (Ger. pat. 507,743) **25.** Disinfecting, cosmetic or tanning agent (Swiss pat. 139,327) **17.** Evaporators for the manufacture of gums, gelatins, etc. (Fr. 687,780) **28.** Vulcanizing rubber to leather (U. MACKSCH, K.: **Das Färben von Leder und Lederwaren.** 3rd ed., enlarged. Berlin: Verlag der deutschen Sattler und Tapezierer Zeitung. Berg und Schoch. 154 pp. Reviewed in *J. Intern. Soc. Leather Trades' Chem.* **14**, 593(1930).

ROUSSET, H. J.: **Travail du cuir.** Paris: Ch. Beranger. 169 pp. F. 30, plus postage. Reviewed in *J. Intern. Soc. Leather Trades' Chem.* **14**, 680(1930).

Treating **skins.** SOC. FINANCIÈRE DE CRÉDIT MOBILIER ET IMMOBILIER. Fr. 687,977, Mar. 28, 1929. Skins from which wool or hair is to be removed are treated with a mixt. of epidermose (waste from skins), caustic soda and water, to which BaS, Na_2CO_3, colophony and resorcinol or phenol may also be added.

Treatment **of fibrous animal skins.** M. BOUSSART. Belg. 368,922, April 30, 1930. The hides are treated with a hot, weak H_2SO_4 soln. Any acid remaining on the recovered hair is subsequently neutralized by a suitable liquor.

Treating **pelts and skins, etc.** FIRMA RICHARD F. SCHMIDT. Ger. 507,835, May 4, 1928. Pelts and skins, etc., with a thin or delicate inner face, are coated at this face with leather with the same degree of elasticity.

Recovering **dye from hides and residues.** MAX VOGEL. Swiss 139,893, June 18, 1929. The hides, etc., are placed in the inner chamber of a double-walled vessel and heated by electricity. Turpentine is added and the recovered dye passes through a pipe to a receptacle.

The recovery **of hair and wool from hides.** H. A. BARE, (MISS) M. J. KERREMANS and H. M. J. A. DE COSTER. Belg. 368,267, April 30, 1930. Hides are immersed in a soln. contg. 0.5 g. melorian B9, 0.5 g. cykloran M, 0.05 g. $AgNO_3$ and 6% H_2SO_4 per l. of water. The bath is heated to about 70°.

Drying **hide-steeping drums.** PAUL HERTZSCH. Ger. 509,902, Aug. 15, 1928.

Tanning **agent.** J. R. GEIGY A.-G. Swiss 138,884, July 30, 1928. The agent is prepd. by condensing ω-chloromethylenesalicylic acid with Na phenol-*p*-sulfonate in dil. acid.

Tanning **agents.** I. G. FARBENIND. A.-G. Fr. 687,411, Dec. 30, 1929. Tanning prepns. are made by forming solns. of TiO_2 and H_2SO_4 with a basicity of about 0.3 to 0.5 mols. of H_2SO_4 for 1 mol. of TiO_2 (equals about 70–55% of basicity), concg. these solns. or bringing them to a solid form.

Tanning and other treatments for lustering, etc., of lambskins and sheepskins. MYRON LASKIN. U. S. 1,788,026, Jan. 6. After tanning, the wool sides are combed and clipped, the skins are dyed and they are then directly immersed in an aq. emulsion contg. about 1% of oil such as sulfonated neat's foot oil. Other details of treatment also are described.

Treating tanning solutions. ANDREAS G. WACKENREUTER. U. S. 1,786,880, Dec. 30. A tanning soln. such as quebracho ext. or the like is subjected to the selective action of hides to effect tanning and after the hides are sepd. from the soln., solids are removed from the latter and the soln. is coned. to recondition it. App. is described.

Solvent for use in the tanning industry. R. BOTSON AND J. KAMP. Belg. 369,808, May 31, 1930. Rubber is distd. in a retort; the liquid remaining in the retort is decanted, purified with an alkali, then with H_2O and finally with an acid; after neutralizing it is fractionally distd. to obtain fractions, b. 70–200° and 201–360°, which are used in the tanning industry.

Neutralizing iron-tanned leather. OTTO RÖHM. Ger. 508,502, June 11, 1927. The leather is neutralized by phosphates, optionally mixed with bicarbonate, calcined soda, NH_3, etc.

Coloring leather. CHEMISCHE FABRIK VORM. SANDOZ. Ger. 509,925, Jan. 6, 1928. Colors fast to washing and to soap are imparted to leather, especially Samian leather, by pretreating the leather with oxidizing agent and coloring with S dyes or vat dyes. In an example, Samian leather is treated with perborate and dyed green with the S dye obtained by treating 4-alkylaminonaphthyl-4'-hydroxyphenylamine with bisulfate and sulfuric acids. Cf. *C. A.* **24**, 1247.

Colored fibrous stock suitable for making a leather substitute for upholstery, etc. ROBERT C. HARTONG (to Seiberling Rubber Co.). U. S. 1,787,680, Jan. 6. A base stock such as rubber compn. and a filler such as fibers are separately colored, and then mixed with each other.

Artificial leather. RENÉ CLAVEL. Ger. 509,400, Jan. 21, 1926. See Brit. 252,661 (*C. A.* **21**, 2397).

Synthetic horn. FRANZ PABST. Ger. 509,551, Feb. 29, 1928. Transparent horn is prepd. by treating albuminous material with alkylated carbazole. Thus, casein is plasticized with water and alc. and treated with ethylcarbazole.

The oxidation of rubber at atmospheric temperatures. W. C. DAVEY. *Ind. Eng. Chem. Inst. Rubber Industry* **6**, 202–13(1930).—In continuation of earlier expts. which dealt with chem. changes which take place when rubber is oxidized at 70° and 100° (cf. *C. A.* **24**, 4660), the present paper deals with changes which occur in rubber stored at room temp., and the relation of these changes to those at the higher temps. The procedure was to keep a few g. of each sample (macerated and finely divided) in a beaker in darkness, agitate frequently and measure periodically the gain in wt. and the proportion and character of the acetone ext. With rubber-S (100:8) vulcanizates with different states of cure, the degree of cure played a greater part than in the previous expts. at 70° and 100° (the higher the vulcanization coeff. the greater the rate of oxidation), and when these vulcanizates were first extd. successively with acetone and $CHCl_3$, the rate

oxidation was still faster (varying as before with the vulcanization coeff.). In general, aging at room temp. gave very high acetone exts. which reached maxima before the sol. products began to change to insol. products. The final increase in wt. after long aging was higher at room temp. than at 70°, and the acetone ext. and the acetone ext./wt. increase ratios were much higher. The rubber-S vulcanizates were then boiled in 4% NaOH, washed, dried and aged at room temp. (40–97°F.) (1) in dry air, and (2) in air with 65% relative humidity. Oxidation was more rapid than with the untreated vulcanizates; nevertheless it was slow, and it was slower in moist air than in dry air (cf. Stevens, *C. A.* **14**, 3823). The longer the cure, the greater was the difference between the moist and dry air (cf. McKee and Depew, *C. A.* **22**, 2490). The increase in acetone ext. formed in moist air was less than that in dry air. If it is assumed that water is formed during the oxidation, these results can be explained by an equil. (cf. *C. A.* **23**, 4100). Rubber-S vulcanizates which had been extd. with acetone and others which had been extd. with acetone and then with $CHCl_3$ were aged similarly in moist and dry air. In all cases, *i. e.*, regardless of cure and of humidity, acetone extn. increased greatly the rate of oxidation (as judged by acetone exts. and increase in wt.) and acetone and $CHCl_3$ extns. increased it still more. In moist air the increase in wt. was proportional to the vulcanization coeffs., and the acetone ext./wt. increase ratios indicated that the tendency for the acetone-sol. substances to become insol. was greater in moist than in dry air. Though the vulcanizates extd. with acetone and $CHCl_3$ oxidized faster than those extd. only with acetone, the nature of the oxidation was the same. In dry air the wt. increases did not run parallel with the vulcanization coeffs., but they did so in moist air. When rubber-S vulcanizates were exposed in quartz tubes to summer sunlight (up to 45°), the wt. increased rapidly, while the acetone exts. increased to a max. (cf. Yamazaki, *C. A.* **22**, 2084) and then diminished in a way similar to the effect with rubber-S vulcanizates oxidized at 70°. The samples at lower cures showed a higher max. acetone ext. than the more highly cured samples. The relatively low acetone exts. and the acetone ext./wt. increase ratios indicated a marked tendency toward conversion of acetone-sol. substances to acetone insol. substances in a way similar to oxidation at 70°. The lower the cure, the higher the ratios. With vulcanizates cured with accelerator, oxidation was extremely slow in the dark, and the results are not yet ready for publication. Vulcanizates of rubber 100, S 5, diphenylguanidine 0.75, ZnO 5 with different cures were extd. with acetone and oxidized in darkness. Even after extn. oxidation was very slow compared with that of rubber-S vulcanizates under similar conditions (the wt. increase in the latter case was greater in 1 month than in the accelerated vulcanizates after 13 mos.). When exposed to summer sunlight behind glass, the accelerated vulcanizates oxidized in a way more nearly similar to rubber-S vulcanizates than in darkness. Therefore heat but in conjunction with the attendant heat gives an effect similar to that at 70°. A comparison of the oxidation effects at 70° with those from exposure to sunlight showed that at the same time the increases in wt. were higher in sunlight than at 70°. Probably the wt. increases of vulcanizates exposed to sunlight are higher than after oxidation at 70° in darkness, because the losses of volatile products were not so great. The acetone exts. after exposure to sunlight were higher than at 70° but lower than at room temp., and the acetone ext./wt. increase ratios were higher after exposure to sunlight than at 70° but lower than at room temp. in darkness. The acetone exts. and the acetone ext./wt. increase ratios of the accelerated vulcanizates reached very high values, with no max. The acetone ext. of the rubber-S vulcanizate reached a max. which was higher than that at 70°. Though exposure directly to sunlight behind glass results in greater oxidation than at 70° (judged by increases in wt.), the extent to which the acetone ext. characteristic material is not so complete as it is at 70°. C. C. DAVIS

Rubber pigments. F. HARRIS COTTON. *India Rubber J.* **80**, 727–9(1930).—This is a discussion of the requirements of a rubber pigment, the use of Sb sulfides and Sb oxides, and red Fe oxide. C. C. DAVIS

Fillers and their functions. II. F. HARRIS COTTON. *India Rubber J.* **80**, 216–7, 348 (cf. *India Rubber J.* **80**, 138(1930).—The discussion includes resistance to abrasion, black, ZnO, china clay, Mg carbonate, the nature of vulcanization, reclaiming, different types of reclaimed rubber and the advantages of reclaimed rubber. Some notes on curing conditions. E. F. POWELL. *Trans. Inst. Rubber Industry* **6**, 184–201(1930). The paper, which is essentially engineering, describes new expts. on

certain phys. aspects of large-scale vulcanization, some of which are related to earlier expts. by Perks (cf. *C. A.* **23**, 308), and all of which deal with the problem of obtaining repeated uniform cures in production. The work includes studies of variations in the internal temp. of open steam vulcanizers of different types, internal heating of airbags by air and steam, cure penetration and the effect of tire-tread pattern on this penetration A general discussion follows the paper. C. C. DAVIS

Control of uniformity of press cures. H. G. BIMMERMAN. *Rubber Age* (N. Y.) **28**, 307–8(1930).—Mech. problems are discussed. C. C. DAVIS

Some new developments in the physical testing of rubber. A. A. SOMERVILLE. *Trans. Inst. Rubber Industry* **6**, 130–69(1930).—A review and discussion of certain recent developments in testing which approach service conditions more closely than the older conventional methods. The subjects include standardization and interpretation of tests, stress-strain curves at low elongations (cf. S., Ball and Edland, *C. A.* **24**, 4957), fatigue tests, flex-cracking, compression and cutting tests, and aging at various elongations (cf. S., Ball and Cope, *C. A.* **24**, 987). New data are offered in some cases to show the scope and utility of these developments. Fatigue tests with the de Mattia machine of 6 different vulcanizates cured to different degrees and tested at various elongations up to 300% and at different temps. (100° to —10°) showed that: (1) with increase in the % elongation during the fatigue test the endurance of a vulcanizate diminishes greatly, (2) the frequency of the elongations has (at 300% elongation) no effect on the life, (3) the life is slightly shorter at 100° than at 20° (because as the temp. diminishes the permanent set becomes greater so that less work is done), though a tire-tread vulcanizate was an exception in that its endurance was greater at 100° than at 20° (because of an enormous permanent set at 100°); (4) at 20° the life when fatigued does not depend upon the state of cure, but at —10° and 100° undercured samples showed the greatest endurance and overcured samples the shortest life. The tensile strengths and moduli were lower after the vulcanizates had been fatigued. Addn. of an antioxidant improved the endurance of a tire-tread vulcanizate, particularly after the latter had been aged in O. The de Mattia machine was used for measuring the relative resistances of vulcanizates to cracking when flexed repeatedly by flexing specimens which had been cured with a transverse groove of semicircular cross-section to simulate a non skid design. The presence of an antioxidant decreased greatly the tendency to crack under these conditions. Here cracking occurred sooner at 20° than at 0° or at 50° or 100° With a *compression-cutting machine* like that described by Hippensteel (cf. *C. A.* **22**, 2855, 4272) vulcanizates were tested in various ways to ascertain the importance of aging with and without an antioxidant present; of the thickness of specimen; of whether the specimen was wet or dry; of the state of cure; of the proportion of whiting, C black, ZnO, barytes and "mineral rubber"; of the relation between compression and stress-strain curve, of the effect of aging in O on the compression; and of the effect of temp. on the compression (cf. Ingmanson and Gray, *C. A.* **24**, 4657). The resistance to cutting was diminished by aging in O, and an antioxidant minimized this effect of aging. The highest resistance to cutting and the stiffest compression curve were obtained at 45% humidity, and the lowest resistance to cutting and softest compression curve with the specimens immersed in water. C black imparted the greatest resistance to cutting, followed by ZnO, whiting and barytes. At low concns. C black lowered the resistance to cutting, but unlike the other fillers with greater proportions the resistance became greater than the corresponding vulcanizate with no filler. A small proportion of mineral rubber increased the resistance slightly, while a high proportion reduced it but little. The resistance to cutting was greater at 0° and lower at 100° than at 20°. A general discussion follows the paper C. C. DAVIS

A simple abrasion test machine for rubber. P. A. SIGLER AND W. L. HOLT. *India Rubber World* **82**, No. 5, 63–6(1930).—The new machine which is described and illustrated is the garnet paper machine described in a former publication (*C. A.* **20**, 310) redesigned for greater rigidity and compactness and to hold 3 samples. Quant. results on typical vulcanizates under different conditions are given. C. C. DAVIS

A method for the determination of the adsorption capacity of commercial blacks by means of methylene blue. RUDOLF DITMAR AND KARL H. PREUSSE. *Gummi-Ztg* **45**, 243–4(1930).—A qual. method and a quant. method are described. *Qual.*—Thoroughly agitate the sample (0.5 g.) with aq. 0.001% methylene blue (30 cc.) and filter. If the filtrate is colorless, the black is an active one. *Quant.*—Add in extremely small portions the black to aq. 0.01% methylene blue (50 cc.) at 15°, agitating vigorously, until the supernatant liquid remains colorless, then titrate back with the 0.001% methylene blue until a faint green-blue color remains. Calc. the methylene blue adsorbed by 100 g. of black. On this basis tests gave the following results: Durex O lampblack

, Arrow gas black 0.102, Durex M lampblack 1.01, Cabot gas black 0.153, Durex tra 0.806, Kosmos gas black 2.55, Micronex gas black 1.29. No relation was found veen the absorption capacities and the rates of settling of the blacks from the methyl- blue soln. A *method for detg. the relative wetting of blacks by rubber* was then de- ped. Place thin sheets of crepe (milled for 20 min. and cut about 3 × 3 cm.) on ron screen of coarse mesh, powder the surfaces with the blacks and keep the sheets n oven at 70° for 45 min. If the black is easily wetted by the rubber, a lustrous ish-like coating appears on the surface. With blacks not easily wetted, the powd. ace remains dull. Only the Kosmos and Cabot blacks gave a lustrous surface. canization tests in a rubber mixt. accelerated by tetramethylthiurammonosulfide w d that blacks with a high power of absorption retarded the rate of vulcanization. t. whether this retardation was a result of absorption of S or of accelerator, the vious mixt. accelerated with tetramethylthiurammonosulfide was cured with more an before, under which conditions the mixt. was overcured instead of undercured. s indicates that S rather than accelerator is adsorbed by the gas black, which is at iance with results of Carson and Sebrell (cf. *C. A.* **23**, 5351). If this is so, a black h high absorptive power offers no disadvantage, for the proportion of S need only increased. The overflow during vulcanization with blacks having high absorptive wers is smaller than with blacks of low absorptive power, and the d. of the former cts is the greater. C. C. DAVIS

The **development of rubber reclaiming since the War and its importance in rubber** nufacture. PAUL ALEXANDER. *Gummi-Ztg.* **45**, 416–8(1930).—A further review d discussion (cf. *C. A.* **24**, 6061). C. C. DAVIS

Concentrating **latex.** K. D. P., LTD. Fr. 686,821, Dec. 18, 1929. Latex is concd. by adding mucilages or substances fixing water, *e. g.* carrageen moss or lichen, and heating to a temp. above 60°.

Rubber. MERVYN S. STUTCHBURY. Ger. 509,553, Oct. 30, 1925. Addn. to

419,658. Rubber mixts. are prepd. from concd. latex and filling material by using about 75% latex paste with the desired filling material, vulcanizing agent and coloring matter and a protective colloid. The water content is kept const. during mixing. The whole is then dried and rolled. In an example, 100 parts of 75% rubber latex is made into a paste with soap, 80 parts water, 10 parts ZnO, 10 parts talcum, 30 parts chalk, 5 parts castor oil, 4 parts S and 1 part diphenylguanidine.

Rubber. THE NAUGATUCK CHEMICAL CO. Fr. 688,452, Jan. 18, 1930. The deterioration of rubber is retarded by treating it with a substance obtained by mixing an org. base and a naphthol, almost the whole of the naphthol remaining sol. in a 10% soda soln. Thus, β-naphthol 2 and *p,p'*-diaminodiphenylmethane 1 part are melted together and the product is incorporated in a mass to be used for pneumatic tires. Polyethylenepolyamine, prepd. by heating $C_2H_4Cl_2$ with NH_3 and AcONa in aq. soln., is melted with β-naphthol and a little stearic acid, and the product is incorporated with rubber.

Treating rubber. THE NAUGATUCK CHEMICAL CO. Fr. 688,494, Jan. 20, 1930. Deterioration of rubber is prevented by treating it with a diaminodiphenylmethane or a condensation product of this with CH_2O. An example is given of the use of 4,4'-diaminodiphenylmethane (by treating $PhNH_2$ with CH_2O, and treating the methylenedianiline with $PhNH_2.HCl$).

Electrophoretic deposition of rubber from aqueous solutions. THE ANODE RUBBER CO., LTD. Ger. 509,980, Apr. 29, 1926. The deposition takes place on a conductor permitting the passage of gas and forming part of a suction chamber in which a reduced pressure is maintained.

Preserving rubber. THE B. F. GOODRICH CO. Fr. 688,009, Jan. 10, 1930. Rubber is preserved by treating it with a tetra-substituted hydrazine such as tetraphenylhydrazine or a tetraphenylhydrazine substituted with alkyl, hydroxyalkyl or similar groups. The substituted hydrazine may be incorporated in the rubber compn. before vulcanization. Examples are given of the use of tetraphenyl-, tetrabenzyl-, tetra-*p*-toluyl- and *N,N'*-di-*p*-anisyl-*N,N'*-diphenylhydrazine. These derivs. are prepd. by a regulated oxidation of secondary aromatic amines. Cf. *C. A.* **25**, 617.

Preservation of rubber. SHERMAN I. STRICKHOUSER (to Dominion Rubber Co., Ltd.). Can. 305,668, Nov. 11, 1930. Rubber stock is treated with S, ZnO and an accelerator together with benzil, and then vulcanized. This retards cracking.

Retarding deterioration of rubber. WM. S. CALCOTT and WM. A. DOROTHY (to E. I. du Pont de Nemours & Co.). U. S. 1,787,064, Dec. 30. A small proportion (suitably 1–5%) of 4,4'-diaminobenzhydrol, 4,4'-methylamino-3,3'-dimethylbenzhydrol or other diamino and substituted diaminodiarylhydrols is added to a rubber mix before vulcanization. Numerous compds. suitable for this purpose are mentioned. U. S. 1,787,065 describes the use of *p,p'*-tetramethyldiaminodiphenyl ketone, 4,4'-diaminodiphenyl ketone and other diamino and substituted diaminodiaryl ketones for the same purpose and gives numerous examples.

Inhibitor of oxidation in rubber. ALBERT M. CLIFFORD (to The Goodyear Tire and Rubber Co.). Can. 306,332, Dec. 2, 1930. Rubber is preserved by vulcanizing it in the presence of a tertiary naphthylamine. Cf. *C. A.* **24**, 3925.

Extraction of rubber. V. F. KARIS. Russ. 21,612, Dec. 5, 1927, and 22,[illegible] Jan. 16, 1928. The rubber-contg. material is treated with solvents such as light petroleum fractions to remove admixts. and to ext. the rubber. It is claimed that rubber can be recovered by the above method from larvae of caterpillars breeding on the [illegible] plant.

Apparatus for mixing or masticating rubber or similar materials. DAVID BOWEN and CARL F. SCHNUCK (to Farrell-Birmingham Co.). U. S. 1,787,507, Jan. 6. Structural features.

Incorporating powders in the rubber mixture. L. M. GORBUNOV, S. I. ROSENBERG and S. K. SERDOBOLSKII. Russ. 34,205, Oct. 20, 1928. Powdery materials is first mixed with tars, vegetable or mineral oils, bitumens, pitch, residues, wax, ozocerite, paraffin or ceresin. A liquid or a paste or briquets are prepd. from the above mass which is then incorporated into the rubber mixt. and passed through rollers.

Rubber articles. THE ANODE RUBBER CO. (England), LTD. Fr. 687,691, Jan. 4, 1930. Articles of moderate thickness such as gloves or tobacco pouches are made by dipping a former, porous or not, into an aq. dispersion of rubber, etc., and permitting the deposit on the former to the action of a vaporous, gaseous or liquid coagulating or solidifying agent.

Sponge rubber articles which may be of large size. DUNLOP RUBBER CO., LTD., G. W. TROBRIDGE, E. A. MURPHY, D. F. TWISS and W. G. GORHAM. Brit. 333,952,

May 28, 1929. Various details of app. and procedure are described for producing sponge articles "of practically unlimited size" from frothed dispersions of rubber introduced into molds provided with elec. or other suitable heating devices. Dispersions may be used such as those described in Brit. 332,525–6 (*C. A.* **25**, 437).

Repairing shoe soles with rubber mixtures. CLARK H. GEIPERT. U. S. 1,786,-900, Dec. 30. There is applied to the sole a semi-liquid mixt. contg. rubber dissolved in a solvent such as benzine and also contg. "builders' cement," and water is subsequently applied to cause the cement to set and harden upon evapn. of the solvent and the water.

Rubber-impregnated fibrous materials such as felted wood pulp material. GEORGE A. RICHTER and ROGER B. HILL (to Brown Co.). U. S. 1,787,952, Jan. 6. Material is impregnated with an aq. rubber dispersion, and then treated with a rubber solvent to effect a swelling of the rubber, and the solvent is removed.

Cellular rubber products. HARRY L. FISHER (to B. F. Goodrich Co.). U. S. 1,788,563, Dec. 30. Cellular products are obtained by heating rubber contg. S with a substance of the general formula R-SO_2-X, such as a mixt. of *p*-toluenesulfonic acid and H_2SO_4.

Plastic material from rubber and celluloid. D. S. VELIKOVSKII. Russ. 27,774 and Supp. May 16, 1928. A soln. of rubber and Al soaps (fatty or naphthenic or a mixt. of them) in gasoline dild. with petroleum ether is mixed slowly, with const. agitation, with a soln. of celluloid in acetone or amyl acetate which is added to the rubber-soap soln. The acetone and amyl acetate soln should be first dild. with petroleum ether. The dispersion is evapd. and the material is dried.

Dispersing plastic materials. K. D. P., LTD. Fr. 686,711, Dec. 16, 1929. Plastic materials such as crude, vulcanized or regenerated rubber or factis are dispersed by kneading them in the presence of hydrotropes, with the exception of soaps. Examples are given of the treating of such substances in mixers with Na toluenesulfonate, Na xylenesulfonate, casein and salts of gallic acid. The dispersion is facilitated by the addn. of finely divided solids such as $BaSO_4$, lithopone, quartz powder and lampblack. Cf. *C. A.* **24**, 6063.

Dispersions of plastic materials. K. D. P., LTD. Fr. 686,764, Dec. 17, 1929. Aqueous dispersions of plastic materials such as rubber, gutta-percha, balata or factis are converted to the thixotrope state by bringing the colloids added, such as bentonite or clay or those occurring naturally in the dispersion, to the thixotrope state by the addn. of $NaOH$ or H_2SO_4. Under the term "thixotropy" is included the phenomenon where solns. of colloids with their dispersing agents a plastic gel (sometimes even elastic) which can be transformed by agitation, shocks or pressure to the state of a sol, and the dispersions thus formed when left to rest are transformed afresh to the state of a plastic gel. Dispersions artificially prepd. include the sol of dialyzed Fe_2O_3 which can be converted into the plastic gel by an electrolyte soln.

Synthetic rubber. I. G. FARBENIND. A. G. Fr. 687,808, Jan. 7, 1930. Hydrocarbons of the butadiene series are polymerized by treating them with a homogeneous mixt. of colloidal Na and solid powd. diluents such as NaCl.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 333,804, May 16, 1929. Polymerization of diolefins such as butadiene is effected in the presence of hydrazine or its derivs. such as hydrazoisobutyric acid, hydrazine dicarboxylic acid ethyl ester or Na phthalic acid hydrazide and of oxidizing agents such as H_2O_2 or its compds. with org. substances such as betaine, urea or NaOAc or inorg. compds. such as perborates, percarbonates or the prepn. of KF with H_2O_2, and air or O_2, ozonides or enzymes also may be used, together with various specified emulsifying agents of different characters. Several examples are given.

Synthetic rubber. I. G. FARBENIND. A.-G. Fr. 686,934, Dec. 19, 1929. Sol. polymerization products are prepd. from butadiene hydrocarbons in aq. suspension or as an aq. emulsion in the presence of oxidizing agents, by operating in the presence of substances which prevent the formation of difficultly sol. products, such as phenols, thymol, hydroquinone, resorcinol, pyrocatechol, pyrogallol, AcOH or aldol resins, or acetone and its condensation products. Certain inorg. substances such as I, colloidal S or arsenious acid may also be used.

Synthetic rubber. I. G. FARBENIND. A.-G. Fr. 686,960, Dec. 19, 1929. Products resembling rubber are prepd. by polymerizing 1,3-butadiene diluted with over 25% of an aliphatic ether of low b. p. such as Et_2O or Me_2O.

Rubber like product from mineral oils. E. W. HULTMAN. Brit. 333,901, Feb. 18, 1929. See U. S. 1,704,104 (*C. A.* **23**, 2071).

Vulcanization of rubber. SIDNEY M. CADWELL (to the Dominion Rubber Co.,

Ltd.). Can. 305,664, Nov. 11, 1930. A rubber mixt. contains S and a Cl-contg. deriv., a product of condensation of aldehydes having 2–7 C atoms in the open chain with primary aromatic amine.

Vulcanization of rubber. SIDNEY M. CADWELL (to The Dominion Rubber Co., Ltd.). Can. 305,666, Nov. 11, 1930. The rubber mixt. contains ZnO, a vulcanizing agent and a phenylmethylenebis compd. of a dialkyldithiocarbamate capable of hydrolyzing in aq. alc. in the presence of NaOH at least as rapidly as does diphenylmethyl dimethyldithiocarbamate under the same conditions; further a basic material is introduced during the vulcanization.

Vulcanizing rubber to leather. LEON B. CONANT (to Standard Patent Process Corp.). U. S. 1,787,145, Dec. 30. Leather coated with rubber cement and heated to adaptation for hot vulcanization is united with and vulcanized to a rubber compn. Cf. *C. A.* **24**, 4666.

Vulcanized oil products. D. GESTETNER, LTD. Ger. 508,418, Nov. 27, 1925. See Miller (*C. A.* **21**, 2576).

Apparatus for devulcanizing rubber by digestion with alkali or acid, etc. BYRON R. BARDER (to Biggs Boiler Works Co.). U. S. 1,787,891, Jan. 6. Structural features

CHEMICAL ABSTRACTS

Vol. 25. MARCH 10, 1931 No. 5

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Test tube. A. KUHN. *Chem.-Ztg.* 54, 908(1930). J. H. MOORE

A new buret for the determination of unsaturated and aromatic hydrocarbon oils. J. HORMÁNEK. *Chem.-Ztg.* 54, 908(1930).—The detn. is made by shaking with H_2SO_4, as with the Bunte gas buret. J. H. MOORE

An automatic zero device for gas burets. H. DREHSCHMIDT. *Gas u. Wasserfach* 241–2(1930).—A capillary tube is fused into the lower part of the buret, terminating with a bend, at the zero point of the buret. An excess of gas is taken into the buret and the excess forced out into bulbs at one side by manipulation of the leveling bulb. It is claimed that the app facilitates rapid and accurate adjustment of the vol. to zero. R. W. RYAN

Evaporation of large quantities of liquids in the laboratory. C. BLACHER. *Chem. Ztg.* 1930, 534.—The supply flask, inverted over the evapg. dish, has a 2-hole stopper with narrow glass tubes, both extending below the rim of the dish but 1 deeper than the other. Cf. Fuchs (*C. A.* 25, 1). J. H. MOORE

A new revolvable high-vacuum manometer. MAX BRUNNER. *Helv. Chim. Acta* 13, 7(1930).—The app. is a McLeod manometer designed for pressures down to 0.001 mm., and is especially suitable for org. labs. J. H. MOORE

A new photoelectric photometer. HORST TEICHMANN. *Naturwissenschaften* 18, 1130(1930).—The photoelec. effect of a Cu-Cu_2O cell is utilized. A Cu plate coated with Cu_2O on both sides is provided with 2 transparent electrodes (Cu wire netting), held together by 2 quartz or glass plates. A mirror galvanometer (null instrument) connected with the 2 Cu_2O layers makes the combination to a photometer unit for comparison of 2 light sources one on each side of the cell. B. J. C. VAN DER HOEVEN

New pycnometer. FRITZ G. HOFFMANN. *Chem.-Ztg.* 54, 936–7(1930).—This is formed by a wide-mouth tube of about 50 cc. capacity hung in a beaker of water at the desired temp., filled with water to a fixed point and weighed, then weighed with the stopper with the solid and water filled to the same point. J. H. MOORE

Contribution to the technic of laboratory vacuum evaporation and distillation. II. The discharge of the residue and improvement of the apparatus by means of a cooler. HANS N. NAUMANN. *Chem. Fabrik* 1931, 4–7.—The dimensions, capacities, flow velocities and vol. are given for several app.; also, a detachable bottom tube for the removal of residues, a metal cooler and a device to prevent foaming and splashing from Kjeldahl flasks are described, with a short bibliography. Cf. *C. A.* 23, 1186, 5079; 24, 1553, 1768; 25, 440. J. H. MOORE

Apparatus for six simultaneous distillations in one flask. NORMAN L. KNIGHT. *Ind. Chem., News Ed.*, 8, No. 22, 3(1930); illus. E. J. C.

Apparatus for the automatic and safe distillation of ether, alcohol, chloroform, etc., under reduced pressure. CHARLES LAPP. *J. pharm. chim.* [8], 12, 498–502(1930).—A constant level is regulated by a 3-way stopcock. The liquid to be distd. is automatically fed into the top bulb of a glass fractionating column (*A*) connected below with a horizontal (Allihn) condenser. The outside water of this is warmed to about 40° by means of an elec. 30-candle lamp through the medium of a Pb serpentine tube surrounding it and attached to the condenser. The residual fluid runs off into a flask at the end of the system. The vapor in *A*, meeting the cold fluid fed in drop by drop, at a temp. of about 20°, and is condensed in a Vigreux cooler at about 10°. The distillate collects in a cooled storage flask at the other end of the system, where a partial vacuum is applied, recorded by a gage. The entrance of air automatically stops the flow of Et_2O–H_2O or $CHCl_3$–H_2O are readily sepd. in 1 operation. Very little supervision is required. S. WALDBOTT

An electrically heated melting-point apparatus. CHARLES E. SANDO. *Ind. Eng. Chem., Anal. Ed.* 3, 65(1931).—The Thiele-Dennis tube (*C. A.* 14, 1237) is modified

to a combination Roth-Thiele-Dennis tube with which it is possible to reach 300° in about 25 min. J. H. MOORE

A small apparatus to produce very low temperature. MARTIN RUHEMANN. *Z. Physik* **65**, 67–74(1930).—The Joule-Thomson effect in combination with the Linde principle is applied to the liquefaction of He or H_2 on small scale. The whole app. is placed in a vacuum beaker and can be constructed in any work shop. To obtain liquid H_2, liquid air and H_2 of 120 atm. are necessary. To liquefy He, liquid H_2 is required and He of 35 atm. By regulation of the gas flow the app. may be used as a *cryostat*. EGON BRETSCHER

Practical improvements in the field of gas analytical investigations. E. VOSSIECK AND A. SCHMITZ. *Chem. Fabrik* **1930**, 529–31.—Portable and stationary *app.* designed by the authors are described in detail for analyses including combustion over CuO. The combustion section is independent of the 1st absorption section, so that 2 analyses may be running at the same time. J. H. MOORE

An improved absorption tube for combustion analyses. W. D. TURNER. *Ind. Eng. Chem., Anal. Ed.* **3**, 63(1931).—The app. is especially designed for solid absorbents, the novel feature is a ground-joint cap with inlet and exit tubes instead of a stopper. J. H. MOORE

Holder for mercuric chloride in the Gutzeit test. G. H. DAVIS. *Analyst* **56**, 30 (1931).—A Sn screw cap is cut from a mailing tube and forced over a tightly fitting rubber stopper, which has a hole in the middle coinciding with a hole in the Sn cap. The $HgCl_2$ paper is placed on the stopper covering the 8 mm. hole, the cap is screwed on and the stopper pushed on the end of the Gutzeit tube so that the vapors contg AsH_3 must pass through the paper. W. T. H.

Apparatus for the detection of traces of fluoride by the etching method. R. E ESSERY. *Analyst* **56**, 38–9(1931).—The app. consists of a Pb casting, 2 in. across the bottom, 1.5 in. across the mouth and 2 in. high. The mouth is ground flat and polished, the vessel holds 3–4 cc. of liquid. The manner of carrying out the test is described. W. T. H.

Apparatus for continuous leaching with suction. J. F. FUDGE. *Ind. Eng. Chem., Anal. Ed.* **3**, 114(1931).—The app was designed for *leaching soils* in a Gooch crucible and consists of an inverted Erlenmeyer flask with a 2-hole stopper with glass tips, 1 about 0.25 in. longer, extending into the crucible. J. H. MOORE

A new device for determining the potential of cells with very high internal resistances. GEROLD SCHWARZENBACH. *Helv. Chim. Acta* **13**, 865–9(1930).—A modification of Stadie's app. (*C. A.* **23**, 4598) is described in detail and results are given. J. H. MOORE

Improvement of thin film cesium photoelectric tube. S. ASAO AND M. SUZUKI. *Proc. Phys.-Math. Soc. Japan* [3], **12**, 247–50(1930).—An improved photoelec. cell of the Cs vacuum type is described. CsO is deposited on a Ag cathode in the cell A film of metallic Cs is formed on the CsO. A thin layer of either Ag or Au on the Cs is then deposited and the cell is baked at a temp. of 250°. This type cell is more sensitive than the older type cell, which did not have the final Ag or Au coating. The new cell is very sensitive in the red, and the long wave-length limit, λ_0, moves out toward the infra-red. A current of 40μ amp. (sometimes as high as 48μ amp.) per lumen can be obtained from a gas-filled lamp at 2700°. An increased sensitivity is gained by the use of K or Rb instead of Cs; this is to be reported later. Sensitivity curves are given. WILLIAM E. VAUGHAN

Laboratory extraction apparatus. A. M. GALKIN. Russ. 36,138, Nov. 29, 1928.

Laboratory extraction apparatus. N. D. PRYANISHNIKOV. Russ. 55,269, Sept. 25, 1929. In an extractor connected with a reflux condenser by a side arm the latter is provided (on the end connected with the lower end of the condenser) with a buret for measuring the water condensed from the evapd. solvent.

Apparatus for automatically controlling the humidification of air. SAMUEL M. ANDERSON (to B. F. Sturtevant Co.). U. S. 1,789,268, Jan. 13. Light variations produced by condensation of moisture from the air affect a photoelectric cell and through it an elec. control system for regulating a humidifier.

Apparatus (utilizing combustion gases) for heating and humidifying air. EVERETT S. BUCK (to General Iron Works Co.). U. S. 1,788,447, Jan 13. Structural features.

Apparatus for conditioning air by water sprays. GUY F. KELLEY. U. S. 1,789,141, Jan. 13. Structural features.

Bubble tower. YA. E. BEZGINSKII. Russ. 63,405, Jan. 31, 1930. In a gas-drying bubble tower, the lower and middle sections are heated by coils placed in the walls.

The gas enters the lower section, passes a number of trays contacting with H_2SO_4 flowing downward, and leaves the upper part of the tower after passing through a layer of coke. The acid layer on the trays can be regulated by siphons connecting the upper and lower trays.

Recording calorimeter (Junkers type). ADOLF OXEN. Ger, 510,372, Dec. 13, 1929.

Calorimeter for flowing gases or liquids. WM. RIENKS. Ger. 510,143, May 13, 1928.

Thermoelement for measuring radiation. RUDOLF HASE. Ger. 510,759, Dec. 21, 1927.

Radiant reading pyrometer. JULIUS SCHÜNEMANN (to Hartmann & Braun A.-G.). U. S. 1,788,849, Jan. 13. Structural features.

Filter. A. G. DAUMAN. Russ. 18,114, July 12, 1927. A lab. filtering device provided with a centrifuge is specified.

Air filters. IVOR L. BRAMWELL, COLIN W. H. HOLMES and THE BIRTLEY IRON CO., Fr. 688,691, Jan. 22, 1930.

Filter for purifying compressed air. FERDINAND R. DE PAUW. Fr. 689,499, Feb. 6, 1930.

Apparatus for separating gases. ADOLF BURSCHEL. Fr. 690,372, Feb. 21, 1930. See Ger. 488,245 (*C. A.* **24**, 2335).

Apparatus for separating solids from gases. EUGÈNE C. SAINT-JACQUES and SOC. NOUVELLE DE METALLISATION. Fr. 690,558 and 690,560, Apr. 29, 1929. An app. is described for sepg. solids from gases particularly suitable for the *lime and cement industries* and for *furnaces producing* SO_2.

Apparatus for separating finely divided solids from a stream of air or other gases. WM. A. SMITH (to Pneumatic Conveyance & Extraction (1929), Ltd). U. S. 1,788,851, Jan. 13. Structural features.

Gas filter (wetted plate type). K. & TH. MÖLLER G. M. B. H. (Willy Sell, inventor). Ger. 510,089, June 6, 1928.

Device for separating atomized liquids or vapors from gases. SOC. INDUSTRIALE MECCHINE PNEUMOFORE REHSTEINER & C. Ger 510,603, Oct. 5, 1927. The mixt. is led into a chamber through narrow openings where the liquid or vapor loses velocity, and collects or condenses.

Filter for liquids. SVENSKA ACKUMULATOR AKTIEBOLAGET JUNGNER. Ger. 512,388, Nov. 3, 1926. This corresponds to Brit. 272,841.

Filter candles. LÉON ROGER. Fr. 688,781, Jan. 24, 1930. The porous material of the candle is reënforced at the point of support.

Edge filter for filtering liquids. J. A. PICKARD and F. ROGERS Brit. 334,569, May 7, 1929.

Apparatus for filtering sugar solutions, oils or other liquids under pressure. A. R. JAHN. Brit. 334,663, July 17, 1929. The liquid passes successively, in a serpentine path, through compartments of a closed casing which are filled with filtering material, such as charcoal, sawdust, sand, kieselguhr or the like. The app. also may be used for *treating ores with cyanide solns.*, for *filtering cyanide solns. of metals through material such as Zn turnings to effect pptn. of the metals* or for *hydrogenating oils* by passing in contact with Ni shavings or Ni-plated kieselguhr.

Filter for separating solids from liquids. BRITISH GLUES & CHEMICALS, LTD., AKT. GES. FÜR CHEMISCHE PRODUKTE VORM. H. SCHEIDEMANDEL and W. WACHTEL. Brit. 334,585, June 6, 1929.

Apparatus for separating oil and water, etc. WHITE OIL SEPARATORS, LTD. Ger. 510,087, June 3, 1928. See Brit. 285,707 (*C. A.* **23**, 275).

Filter head for oil filters. CHARLES L. MCCUEN (to General Motors Corp.). U. S. 1,788,884, Jan. 13.

Filter bed. FRANK DELERY. U. S. 1,788,383, Jan. 13. Structural features.

Filter cloths. AUGUSTE LEMAIRE. Fr. 689,028, Jan. 28, 1930. Methods of making filter cloths with reënforced edges.

Filter cloth suitable for use in filter presses. CORNELIS H. CAALS. U. S. 1,788,657, Jan. 13. Structural features.

A continuous filter press. V. I. FILIN. Russ. 46,645, May 8, 1929. Constructional details.

Method and apparatus for washing filters having loose filtering material. ROBERT BREDE. Ger. 512,390, Sept. 19, 1925.

Heating means for rotating-plane suction filters. MASCHINENFABRIK BUCKAU R. WOLF A.-G. Ger. 512,389, Jan. 25, 1927.

Laboratory apparatus for analyzing gases by combustion. SELMAN S. LEWINSOHN. Ger. 512,358, Aug. 11, 1926.

Device for determining the density of gases. JACOB M. SPITZGLASS. Ger. 510,622, Jan. 15, 1928. Details are given.

Apparatus for determination of density of gases. SH. SH. PODOLSKII. Russ. 42,970, Mar. 19, 1929. The density of gases is detd. by the decrease in wt. of a solid body placed in the gaseous medium, as shown by the amount of slackening of a spring placed in a permanent magnetic field, through which spring an elec. current is passed and which is tightened by the above weight. This operation is carried out in the gaseous medium and *in vacuo*.

Device for determining the moisture content of gases. I. G. FARBENIND. A.-G. (Paul Gmelin, Albert Ernst and Fritz Ranke, inventors.) Ger. 510,953, Nov. 25, 1927. A dew-point device is used and visual observations are replaced by a radiation-sensitive device such as an elec. resistance thermometer.

Arrangement for estimating the calorific power of gases. SIEMENS & HALSKE A.-G. (Heinz Grüss, inventor.) Ger. 510,952, Mar. 18, 1928. The app., including an elec. resistance thermometer, is described.

Centrifugal purifier for air or other gases. MAX AURIG. Fr. 690,443, Feb. 22, 1930.

Apparatus for purifying vapors, gases and liquids. P. S. GRACHEV and A. N. ANTIPOV. Russ 12,770, Dec. 4, 1926. Constructional details.

Gas purifier. V. D. POGORELUII. Russ. 39,069, Jan. 16, 1929. Structural details

Apparatus for purifying gases by a countercurrent of liquid. CARRIER ENGINEERING CO., LTD. Fr. 689,620, Feb. 8, 1930.

Apparatus for treating gases with atomized liquids. STELLAWERK A.-G. VORM. WILISCH & CO. (Karl Kuhn, inventor). Ger. 512,128, Oct. 20, 1925.

Container for liquid air, oxygen, etc. I. G. FARBENIND. A.-G. Ger. 510,577, July 20, 1927. The container comprises a vacuum jacketed vessel filled with a porous adsorbent made from a refined SiO_2 sol which, prior to drying, had a p_H value of less than 7 and preferably between 2-5.

Gas-detecting apparatus. M. H. ESPES. Brit. 334,640, June 19, 1929. Various details are described of an app. of the type employing differential expansion of 2 members, one of which carries spongy Pt pellets.

Apparatus for measuring the viscosity of liquids. DIMITRY TROSCHENSKY. Fr. 690,051, Feb. 15, 1930.

Apparatus for separating liquid particles containing albumin or foam from generated vapors. PAUL KNICHALIK Ger. 510,710, Oct. 22, 1927. The app. includes a drum with a perforated spiral canal.

Apparatus for mixing liquids. I. A. GUSEV. Russ. 67,100, Mar. 26, 1930. A propeller is placed in a pipe through which the liquids are passed.

Device for mixing a liquid in flow with a small proportion of another liquid. OSKAR RITSCHEL. Ger. 512,174, Nov. 5, 1927

Apparatus for mixing a liquid in flow (water) with a small proportion of another **liquid (reagent solution).** OSKAR RITSCHEL. Ger 510,055, Dec. 20, 1927.

Apparatus for producing water containing carbon dioxide. S. A. B. SOC ANON. BREVETTI. Ger. 510,052, Nov 25, 1927.

Apparatus for rapid boiling and evaporation of liquids. WEHRLE-WERK A. G. Fr. 690,506, Feb. 24, 1930.

Plant for cooling liquids with liquids, operating under reduced pressure. WINTERSHALL A.-G (A. Siebers, inventor). Ger 510,417, Jan. 17, 1929.

Apparatus for circulating solutions such as salt solutions and for expelling the solute **to effect concentration.** EDMUND ALTENKIRCH (to Siemens-Schuckertwerke G. m. b. H.). U. S. 1,788,818, Jan. 13. Structural features.

X-ray apparatus (time exposure control device for x-ray photography). S. COX. Brit. 334,639, June 17, 1929. Structural features.

Light-sensitive cells. S. REUBEN (to Arcturus Radio Tube Co.). Brit. 334,409, March 16, 1929. An electrode of Cu_2O is employed in contact with an electrolyte capable of releasing nascent O independently of electrolysis, such as H_2O_2; a cooperating electrode is made of electropos. material, such as Mg, Zn, Cd or Al, or of electroneg. material, such as Se or C. Various structural details are described.

Activating the cathodic surface of a photoelectric element. GOSUDARSTVENNOYE VSESOYUZNOYE ELEKTROTEKHNICHESKOYE OB'EDINENIE. Russ. 61,248, Dec 28, 1929. A gas contg. a high percentage of activated hydrogen is admitted into a previously evacuated container of the photoelec. element.

Thermionic cathodes. G. P. HALLIWELL (to Westinghouse Elec. & Mfg. Co.). Brit. 334,460, Dec. 14, 1928. A cathode is formed of a homogeneous body contg. at least one metal of the Ni group, a deoxidizing agent such as Ti, Th, V, Ta, Si, Mn, Al, Ce, Zr or other rare earth metal, together with one or more alk. earth metal oxides disseminated throughout the material. Various details and examples are given.

Cathodes for electron tubes. SOC. DES ÉTABLISSEMENTS INDUSTRIELS E. C. GRAMMONT & ALEXANDER GRAMMONT. Ger. 512,263, Feb. 21, 1928. See Fr. 661,813 (*C. A.* 24, 270).

Oxide cathodes for electron tubes. FRITZ TÖDT. Ger 512,343, Mar. 21, 1929. The metallic carrier for the oxide is placed in an aq. soln. of unstated compn. together with a baser metal; the metals are conductively connected to form a galvanic chain. After about a day, a sufficient incrustation of alk. earth carbonate accumulates on the carrier.

Electron discharge devices. INTERNATIONAL GENERAL ELECTRIC CO. Ger. 512,362, Dec. 12, 1928. See Brit. 302 315 (*C. A.* 23, 4282).

Electric discharge device. N.-V. PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 334,-329, May 3, 1929. A gas-filled arc discharge tube with 2 or more anodes has a hollow cathode, suitably heated and provided on its inner surface with an electron-emitting substance such as BaO, $Sr(NO_3)_2$ or Zr carbide. Various structural details are described. Cf. *C. A.* 24, 5543.

Film evaporating- and drying-apparatus of the roller type. A. ST. J. GATES. Brit. 334,765, Aug. 6, 1929. Structural features.

Multi-stage evaporating apparatus. J. A. REAVELL. Brit. 334,623, June 11, 1929. Filters are inserted between the stages of an evapg. system comprising 2 or more evaporators working under substantially the same pressure. A 4-stage triple effect app. (various details of which are described) is used for evapg. a liquor consisting mainly of a soln. of Ca acetate, with some NH_3 and org. impurities, such as is obtained in *cellulosic fermentation*.

Ripple device for drying, etc., drums. FELLNER & ZIEGLER A.-G. Ger. 510,396, Nov. 28, 1929.

Drying plant with a number of superposed conveying bands. FRITZ HAAS. Ger. 512,624, Mar. 3, 1928.

Plant for drying pulverulent materials. TECHNO-CHEMICAL LABORATORIES, LTD. Ger. 513,527, Dec. 6, 1927. See Brit. 294,289 (*C. A.* 23, 2021).

Apparatus for drying casein. PASQUIER MEESE ET CIE. Fr. 36,720, Jan. 28, 1930. Addn. to 664,296 (*C. A.* 24, 758).

Shaft furnaces. MASCHINENBAU-ANSTALT HUMBOLDT. Fr. 690,382, Feb. 21, 1930. Means is described for blowing combustion air into the furnaces.

Closure for chamber furnace. ARNOLD BECKERS Ger. 510,560, Oct. 24, 1926.

Electrical closing apparatus for vertical chamber furnaces. BAMAG-MEGUIN A.-G. Ger. 513,717, June 21, 1929.

Arrangement for equalizing pressure in channels of multi-chamber furnaces. A. V. GRUM GRJIMAILO. Russ. 16,552 Mar. 21, 1927. Structural details.

Horizontal chamber oven. ERNST CHUR. Ger. 512,400, Oct. 28, 1926.

Oven for annealing tubes. MAX SCHLIPKÖTER. Ger. 510,209, Jan. 8, 1928. Details of conveying means are described.

Burners for heavy fuels. ALFRED LANSER. Fr. 690,383, Feb. 21, 1930.

Burners for liquid fuel with direct feed. ADRIEN A. BIANCHI. Fr. 689,829, Feb. 13, 1930.

Bunsen burners. HERMANN GUHL. Fr. 688,694, Jan. 22, 1930. The speed and amt of flow leaving the tap are increased by creating a reduced pressure in the section of the mixing tube of the tap by narrowing the initial section of the mixing tube.

Burners using explosive mixtures of high speed of combustion. SOCIÉTÉ L'AIR LIQUIDE (SOCIÉTÉ ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS GEORGES CLAUDE). Fr. 688,744, Jan. 23, 1930. Means is described for obtaining low burning.

Gas burner. BURTON FOUNDRY CO., LTD., and D. F. CAMPBELL. Brit. 334,307, June 17, 1929.

Gas burner suitable for furnaces. WM. M. HEPBURN (to Surface Combustion Co.). U. S. 1,788,716, Jan. 13.

Gas burner of the "ribbon burner" type. WM. B. ENSIGN and LLOYD H. V. REYNOLDS (to Reynolds, Inc.). U. S. 1,789,226, Jan. 13. Structural features.

Pressure and air proportion-control apparatus for gas burners. GARNETT W. MCKEE. U. S. 1,788,925, Jan. 13.

Burners for gas-producing furnaces. N. V. SILICA EN OVENBOUW MAATSCHAPPIJ. Fr. 36,901, Aug 4, 1928. Addn. to 665,658 (*C. A.* **24**, 950).

Combined temperature and time control for gas-fired heating apparatus. JOSEF MOSING. Austrian 119,284, April 15, 1930.

Traveling grate. UNDERFEED STOKER CO., LTD., and JOHN W. WRAY. Ger. 512,158, July 14, 1928. This corresponds to Brit. 306,983.

Heat-exchange apparatus suitable for use as a condenser. RAYMOND N. EHRHART (to Elliott Co.). U. S. 1,788,386, Jan. 13. Structural features.

Helical tubular heat-exchange apparatus suitable for use as a condenser. ELECTROLUX, LTD. Brit. 334,333, July 19, 1929. Structural features.

Electric water heater. OTTO GRAETZER. U. S. 1,788,669, Jan. 13. Structural features.

Gas valve suitable for use with water heaters. CLARENCE H. MORROW (to Hotstream Heater Co.). U. S. 1,788,537, Jan. 13.

Rotary kiln and associated cooling drum suitable for calcining and clinkering. FRITZ LUTHER (to the firm of G. Polysius). U. S. 1,788,839, Jan. 13. Structural features.

Device for distributing dry materials fed to furnaces. ZAHN & CO., BAU CHEM FAB. G. M. B. H. Ger. 510,091, Feb. 12, 1928. The device is especially intended for use in the manuf. of Na_2SO_4 from NaCl and H_2SO_4.

Device for conveying goods through annealing, etc., ovens. BENNO SCHILDE MASCHINENBAU-A.-G. (Frederic R. Colby and Arnold L. Larsen, inventors.) Ger. 512,491, May 11, 1928.

Device for taking samples of bulk materials such as cottonseed. GUY S. MILLER. U. S. 1,789,246, Jan. 13. Structural features.

Apparatus for testing vessels (such as pots used in zinc cells) for leakage. H. A. BUMKE GES and AUTOM SPEZIAL-MASCHINEN GES. Brit. 334,680, April 10, 1929. Structural features.

Apparatus for compressing chlorine gas. KREBS & CO., G. M. B. H. Fr. 688,669, Jan. 22, 1930.

Apparatus for decomposing salts. HOWARD B. BISHOP. Fr. 688,820, Jan. 24, 1930. An app. is described for treating salts with acids, such as $NaNO_3$ with H_2SO_4, in which the salt is heated by itself below the point of fusion of the solid elements and above the b. p. of the acid to be produced, before bringing it into contact with the decomposing acid. The reaction vessel has agitating means and jets for introducing the acid.

Apparatus (with a slotted suction tube) for extracting fluids from cloth or other materials. ALBERT BIRCH. U. S. 1,789,132, Jan. 13.

Apparatus for kneading and agitating plastic masses. S. F. PAPICH. Russ. 45,508, April 19, 1929.

Agitators for sedimentation apparatus. THE DORR CO. Fr. 689,518, Feb. 6, 1930.

Apparatus for producing high vacuums. SOC. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 690,169, Feb. 18, 1930.

Vacuum flask. L. T. SAWNEY. Brit. 334,262, June 1, 1929. Mech. details.

Hollow vessels of fused silica. G. A. MILLAR (to British Thomson-Houston Co., Ltd.). Brit. 334,470, Dec. 20, 1928. App. and various details of operations are described.

Device for fusing metals, salts, etc., in crucibles. TRAUGOTT METZGER. Ger. 512,338, Dec. 9, 1928. This describes a device intended to be inserted into material solidifying in a crucible, and designed so as to avoid development of strains when the material is re-fused.

Siphon device suitable for use with "desert water bags," etc. LOUIS B. DI SPAIN. U. S. 1,788,709, Jan. 13. Structural features.

Thermostatic electric switch. FRANK E. STOVER. U. S. 1,788,640, Jan. 13. Structural features.

Thermostatic electric switch. ROY D. MAILEY (to General Electric Vapor Lamp Co.). U. S. 1,788,922, Jan. 13. Structural features.

Thermostatic electric switch. WILBUR E. LAGANKE. U. S. 1,789,183, Jan. 13. Structural features.

Thermostatic and electric control system suitable for fuel-supply-valve control. CHRISTIAN WILHJELM. U. S. 1,788,787, Jan. 13. Structural features.

2—GENERAL AND PHYSICAL CHEMISTRY

The present scientific picture of the world. RICHARD V. MISES. *Naturwissenschaften* **18**, 885–93(1930). B. J. C. VAN DER HOEVEN

The blue color of sea water. RICHARD WILLSTÄTTER. *Naturwissenschaften* **18**, 868–70.—It is suggested that the blue color of sea water is caused by small quantities of dissolved complex Cu compds. (ammino salts). B. J. C. VAN DER HOEVEN

An ammonia world. W. CONARD FERNELIUS. *J. Chem. Education* **8**, 55–62 (1931).—An imaginative article picturing a "planet" in which the H_2O of the earth is replaced by liquid NH_3. Because of the similarities in certain properties between NH_3 and H_2O, an "ammonia world" would have many characteristics in common with a "water world." W. C. FERNELIUS

Platinum resistance thermometry. I. Calibration of bridge and annealing of platinum bulb. MOTOTARŌ MATSUI AND SHUJI KAMBARA. *J. Soc. Chem. Ind.* (Japan) **33**, Suppl. binding 401–3(1930).—To obtain an accuracy of 0.01° in resistance thermometry it is necessary to calibrate and det. the temp. corrections of the bridge used, and to anneal the Pt bulb sufficiently. The bridge was calibrated by the method of Mueller (*C. A.* **11**, 1). **Two thermostats were used to obtain temp. corrections. An** oil bath contained **a standard resistance. The bridge was contained in an air bath** and the temp. **varied between 14° and 32°. The bulb was annealed at 400–600° and** R_0 measured **to det. when a steady state had been reached. Fourteen annealings were**

required to obtain a const. R_0. **II. Determination of constants of platinum bulb and accuracy of resistance thermometry.** *Ibid* 403–7.—The consts. R_0, R_{100} and δ were obtained by means of the annealed bulb and calibrated bridge. By differentiating R_t, R_0 and R_{100} with respect to temp., each max. allowable error was obtained. If an accuracy of 0.1° is satisfactory it is unnecessary to calibrate the bridge. The deviation of R_0 and R_{100} from the mean value was less than ±0.000010. From observations of the S b. p. the deviation of δ was less than ±0.000050. With these limiting conditions the accuracy of resistance thermometry is 0.01° below 500° and 0.1° above that temp. ALLEN S. SMITH

Optical pyrometry. A. C. EGERTON AND M. MILFORD. *Proc. Roy. Soc.* (London) A130, 111–9(1930).—The advantages of a magnifying pyrometer are pointed out. A monochromatic filter using a "didymium glass" is described which transmits light between 5740 and 5600 A. U. The calibration of a pyrometer by use of a wedge as a blackbody source or a Pt tube provided with a small hole is discussed. The temps. are detd by melting small pieces of metal on the outside of the tube or wedge, or preferably by hanging a wire down the middle of the tube. Two monochromatic filters made it possible to det. the color temp. H. W. LEAHY

Correction for adsorption in physicochemical measurements of molecular and atomic weights. ENRIQUE MOLES. *Anales asocn. quím Argentina* **18**, 114–23(1930).—The adsorption per unit of calcd. surface is found experimentally to be greater on a sphere than on cylindrical tubes. The actual surface of the sphere is believed to be greater than the calcd. surface. Data for relatively small surfaces adsorbing NH_3 and SO_2 agree well with those of Bangham and Burt (*C. A.* **19**, 1215, 2290), who used glass wool having considerable surface, showing that the 2 phenomena are the same. In practice, adsorption correction cannot be eliminated by using vessels of different vols. E. M. SYMMES

A simple principle of the elements. HERBERT HERIBERT. *Z. Elektrochem* 36, 687–8(1930).—A scheme is presented in which the elements of a principal group or subgroup of the periodic system are indicated by mechanical operation of a slider. The app. consists of two identical horizontal strips, one above the other, sepd. by a slider after the manner of a slide rule. Each strip bears the symbols and at. no. of the elements arranged in the order of the at. no. The slider carries definitely spaced arrows some of which point to the upper strip and others to the lower strip. When the arrow at the left end of the slider is set on one of the first 8 elements (He to F) the other arrows point upward to the symbols of the other elements in the principal group, and downward to the symbols in the corresponding subgroup. Similarly, if an arrow is set on the symbol of an element, the elements that belong to the corresponding principal group and subgroup will be indicated by the other arrows on the slider. The spacing of the arrows on the slider is detd. by the fact that the at. no. of the elements in the same groups of the periodic system are sepd. by one of 3 intervals, namely, 2×2^2, 2×3^2 or 2×4^2. R. H. LOMBARD

The frequency of elements and the presence of a nucleus periodicity. R. A. SONDER. *Naturwissenschaften* **18**, 939–40(1930).—The results on periodicity of nucleus structure given by I. and W. Noddack (*C. A.* **25**, 5546) agree with recent data of S (*C. A.* **25**, 7). Previously the same relations had been suggested before there was sufficient evidence (*C. A.* **18**, 497). B. J. C. VAN DER HOEVEN

The basis of chemical atomic weights. A proposal. ARISTID V. GROSSE. *Z. physik. Chem.*, Abt. B, **10**, 395–6(1930).—It is proposed that the basis of at. wts be made He with a value of 4.0000, since it exists with only one kind of atom. This change gives slightly less than integral values for many isotopes and lowers the present values for at. wts. (O = 16) only a little. L. P. HALL

The synthesis of silver sulfide. Atomic weight of sulfur. O. HÖNIGSCHMID. *Z. Elektrochem.* **36**, 639–90(1930).—Samples of purest at. wt. Ag weighing about 10 g. were converted to Ag_2S by heating them at 250° in S vapor carried by a current of N_2. Excess S was removed from the Ag_2S by heating it in O_2-free N_2 for 30 min. at 280°. Ten syntheses of Ag_2S gave, $Ag_2S:2Ag = 1.148630$, and the at. wt. of S = 32.0685 ± 0.0006. Ag_2S is stable between 200° and 300°, and excess S in a synthetic prepn can be removed by heating in this temp. range. Likewise, a sample of Ag_2S that has been made deficient in S through thermal dissocn. or by reduction by H_2, will regain its original wt. within a few hundredths mg. when heated in S vapor between 200° and 300°. Attempts to analyze Ag_2S by reduction with purest electrolytic H_2 at 720° for 160 hrs. did not give satisfactorily quant. results. The wt. of Ag obtained after reduction was 0.1 to 0.2 mg. greater than that from which the sample of Ag_2S had been synthesized. The reduction becomes slower as the end is approached, and if reduction is prolonged

unduly, loss of Ag by volatilization may become significant, especially above 800°.
R. H. LOMBARD

The concurrence of principle and secondary valence. EDUARD HERTEL AND GEORG H. ROMER. *Ber.* **63B**, 2446–52(1930).—Mols. *M*, that form addn. products are considered to have a reacting group, *R*, and a center of addn., *A*. Two such compds. can react to give the following products: I, $R_1—M_1—A_1:::A_2—M_2—R_2$; II, $A_1—M_1—R_1—R_2—M_2—A_2$, III, $A_1—M_1—R_1—M_2—A_1 + R_1$; or IV, $A_1—M_1—M_2—A_2 + R_1—R_2$. The reaction may be altered by changing the groups attached to the two basic mols. $MeOC_6H_2(NO_2)_3$ (V) and $Me_2NC_6H_5$ or dimethyl-β-naphthylamine form addn. products, which on warming rearrange to give picrates of quaternary ammonium bases the Me group wandering. $(NO_2)_3C_6H_2OCHMeCOOEt$ (VI) gives only an addn. compd. V with NH_3 or NH_2Ph gives only MeOH and the amine; no addn. compd. can be isolated. A study of the phase diagram of V and α- (VII), β-naphthylamine (VIII) or 4-bromo-α-naphthylamine (IX) shows that each forms an addn. compd. The compd. with VIII at 150° above its m. p. gives $(NO_2)_3C_6H_2NHC_{10}H_7$. VI with VII and VIII gives no addn. compd. VI and IX give an addn. compd. V and VI form compds. with Ph_2NH. These facts indicate that secondary valence is manifest only by compds. having a reactive group.
V. F. HARRINGTON

Values and inter-relationships of *c*, *e*, *h*, M_p, m_e, *G* and *R*. W. N. BOND. *Phil. Mag.* 10, 994–1003(1930).—Theoretical. The evidence in support of Eddington's $hc/2\pi e^2 = 137$ and Furth's $hc/\pi(M_p + m_e)^2G = (16)^{32}$ is believed to be sufficient. On the basis of these the following are calcd.: $e = (4.779_7 \pm 0.0017) \times 10^{-10}$ e. s. u., $h = (6.550_8 \pm 0.0046) \times 10^{-27}$ erg. sec., $e/m = (1.7688_2 \pm 0.0006_5) \times 10^7$ e. m. u./g., $M_p/m_e = 1846.43 \pm 0.65$ and $G = (6.635 \pm 0.001) \times 10^{-8}$ dyne.cm.²/g.² (c = velocity of light; e = electronic charge; h = Planck's const.; M_p and m_e are masses of proton and electron; G is the gravitational const.)
WILLIAM E. VAUGHAN

Extended energy functions of the hydrogen molecule. P. M. DAVIDSON AND W. C. PRICE. *Proc. Roy. Soc.* (London) **A130**, 105–11(1930).—A math. discussion of the potential energy of H_2.
H. W. LEAHY

Magnetism in discontinuous media. L. W. MCKEEHAN. *Rev. Modern Physics* **2**, 77–97(1930).—This a comprehensive survey of the various theories of magnetism based upon some type of "elementary magnet." The behavior of fluids, mesophases, and ferromagnetic and paramagnetic crystals is discussed. A no. of the theories of ferromagnetic crystals are outlined and criticized, including those of Ewing, Honda and Kaya, Weiss, Piddie, Gans, Mahajani, Akulov, Becker, Heisenberg and Weiss. Bibliography
W. W. STIFLER

Dependence of the susceptibility of diamagnetic metals on the field. W. J. DE HAAS AND P. M. VAN ALPHEN. *Proc. Acad. Sci. Amsterdam* **33**, 680–2(1930).—A preliminary report, covering measurements on a small rod of very pure Bi at 290°, 20.3° and 14.2° K. At room temp. the susceptibility is independent of the field but at the 2 low temps. the susceptibility begins to decrease at higher fields, just as the change in resistance has been found to do.
W. W. STIFLER

Determination of the susceptibility of potassium chromium alum at low temperatures. W. J. DE HAAS AND C. J. GORTER. *Proc. Acad. Sci. Amsterdam* **33**, 676–9(1930). The susceptibility of K Cr alum was measured at 8 temps. between 14.33° and 2.06° K. When these results are corrected for the diamagnetism of the K and sulfate ions and for the H_2O of crystn., they follow the Curie-Weiss law with $\theta = 0.16°$, $C = 36.9 \times 10^{-4}$, and $p = 19.02$ Weiss magnetons. This behavior does not accord with the theories developed by Sommerfeld and Laporte to explain the magneton nos. in the iron group.
W. W. STIFLER

Thermal variation of the magnetic birefringence of *p*-azoxyanisole above the temperature of disappearance of the mesomorphous state. JACQUELINE ZADOC-KAHN. *Compt. rend.* 191, 1002–4(1930); cf. *C. A.* **24**, 2924.—The *Cotton-Mouton effect* was detd. for anisotropic *p*-azoxyanisole between 134.5° and 172.6° in a field of 33,900 gauss. The temp. measurements were accurate to 0.5° and the angles of rotation of the analyzer to 1/1000. Thermal conditions were better than during previous measurements.
FRANK URBAN

The dipole moment of naphthalene and its monohalogenated substitution products. ADOLF PAUL. *Z. physik. Chem.*, Abt. B, **10**, 264–72(1930).—The influence of substitution in the 1- and 2-positions on the magnitude of the dipole moment was studied for $C_{10}H_8$ and its 8 monosubstituted halogen derivs. in C_6H_6 soln. at 20°, methods previously described (*C. A.* **23**, 4857; **24**, 4195) being used. The d., dielec. consts., polarization, and the total polarization were measured for each product over a range of concns. The indices of refraction for H_β, *D* and H_α lines were detd. for

1-fluoronaphthalene as 1.61474, 1.59388, 1.58611 at 19.6° and for 1-iodonaphthalene as 1.72995, 1.70256 and 1.60244 at 19.5°. The 2-halogen derivs. had 0.13 to 0.15, 10^{-18} greater moment than the 1-derivs. Naphthalene had zero moment. All halogens in the 1-position of $C_{10}H_8$ had the same moment as in C_6H_6. L. P. H.

A mechanistic view of the Broglie waves and an extended equation of state for gases. ARTHUR KORN. *Physik. Z.* **31**, 955–7(1930).—The customary equations for compressible liquids may be solved in the form of the *Schroedinger wave equation*. The phenomena of wave mechanics are interpreted as true mech. vibrations of which the de Broglie waves are a special case. No relativity considerations are needed for their explanation. It is shown that c in the *kinetic theory* equation $p = c\mu$ is no longer proportional to the temp., but assumes the form $c = \text{const.} \sqrt{T}\nu$, for large values of the frequency ν. The latter expression also covers *photoelec. phenomena*. F. U.

Kinetic theory of the liquid state. R. O. HERZOG. *Z. physik. Chem.*, Abt. B, 10, 347–46(1930).—Tests of Jager's equation (*Drud. Ann.* **11**, 1077 (1903)) connecting viscosity, internal pressure, radius and velocity of a mol. give good agreement for liquid H and for Hg at higher temps. Jäger's equation is combined with that of Riecke (*Z. physik. Chem.* **6**, 564 (1890)) to relate the previous quantities with mean free path and diffusion. L. P. HALL

The kinetics of the polymerization of vinyl acetate. HOWARD W. STARKWEATHER AND GUY B. TAYLOR. *J. Am. Chem. Soc.* **52**, 4708–14(1930).—The polymerization of pure $CH_2{:}CHOAc$ is shown to follow the unimol. rate law. In PhMe soln. the rate of reaction is retarded. The kinetics of the polymerization are explained on the basis of a chain reaction. $(PhCO)_2O_2$ acts as a trigger catalyst by initiating reaction chains, while S inhibits the reaction. H. W. LEAHY

The changes in volume and temperature that accompany the mixing of organic liquids. I. E. ROGER WASHBURN AND ALBERT LIGHTBODY. *J. Phys. Chem.* **34**, 2701–10(1930).—In an effort to find a relationship between the temp. and vol. changes on mixing org. liquids, the temp. and vol. changes that occur on mixing MeOH, EtOH and iso-PrOH with C_6H_6 or PhMe were measured. The effect of H_2O on the curves for the EtOH-C_6H_6 mixts. was also detd. It was found that between 0 and 1.0 mole fraction of 99.7% EtOH no contraction occurs, while with 99.87% EtOH there is contraction between 0.6 and 1.0 mole fraction. No simple relationship was found between the temp. and vol. changes. H. W. LEAHY

Molecular volume relations of liquid mixtures. W. HERZ. *Z. Elektrochem.* **36**, 850–2(1930).—The mol. vol. of liquid mixts. and solns. is calcd. from the d. and the true vol. of the mols. from the index of refraction. These values are compared with the corresponding values of the components. Data are given for various mixts. of EtOH and $PhNH_2$, Me_2CO and PhH, H_2O and H_2SO_4, PrOH and $C_2H_4Br_2$, H_2O and EtOH, H_2O and Me_2CO, H_2O and KCl, and H_2O and NaCl. JOHN R. HILL

The influence of the period of heating upon the boiling point of certain liquids used in ebullioscopy, with a note on testing the purity of volatile liquids by isothermal distillation. SYDNEY L. WRIGHT, JR., AND ALAN W. C. MENZIES. *J. Am. Chem. Soc.* **52**, 4699–708(1930).—To det. whether the b. p. of a liquid is altered by prolonged heating at the b. p., an app. was constructed that allows a direct differential vapor pressure measurement to be made on 2 samples of a liquid, one having been kept at the b. p. for several hrs., the other elevated to the b. p. from room temp. immediately before measuring. From data obtained on AcOH, Br, C_6H_6 and CCl_4, it is concluded that the vapor pressure of a sample of liquid rapidly elevated to its b. p. is identical with that which it exerts after remaining at the b. p. for several hrs. Delay in attaining internal equil. is not thought to be a factor influencing the measurement of b. p. and vapor pressure when these liquids are used for ebullioscopy. H. W. LEAHY

The motion of xylene drops on the surface of aqueous propyl alcohol solutions. G. G. KANDILAROW. *Kolloid-Z.* **53**, 304–6(1930).—Place a few drops of xylene on water and add, drop by drop, from a capillary pipet, Pr alc. The xylene drops show the same type of movement observed when camphor is placed on an aq. surface. Observation through a microscope shows a very lively action with the xylene drops pushing waves in various directions. Two cases are distinguished: (1) in dil. alc. solns. xylene dissolves in the aq. layer, (2) in concd. alc. solns. Pr alc. dissolves in the xylene drops. ARTHUR FLEISCHER

Remarks on the drop method of measuring surface and interfacial tensions. I. TRAUBE. *Kolloid-Z.* **53**, 300–3(1930).—Polemical with Junker (cf. *C. A.* **24**, 5990) and with Palitzsch (cf. *C. A.* **24**, 1011). ARTHUR FLEISCHER

Crystal growth. W. KOSSEL. *Naturwissenschaften* **18**, 901–10(1930).—A lecture.

The **rate of growth at different crystallographic points is derived from energy considerations** (cf. *C. A.* **22,** 2690; Sommerfeld, Festschrift Leipzig 1928).
B. J. C. VAN DER HOEVEN

The electric resistance of titanium, zirconium and their mixed crystals. J. H. DE BOER AND P. CLAUSING. *Physica* **10,** 267–9(1930).—Previous measurements of the resistance of Ti rods (*C. A.* **23,** 1320) were improved. The rods now used have less sp. resistance and greater purity. Matthiesen's law holds for them as well as for mixed-crystal Ti-Zr rods, *i. e.*, for small admixtures of one metal with the other the product of α and ρ_0 is const. (α is the temp. coeff. of sp. resistance ρ_0). For 5 metals of at. compn Ti-Zr 0-100, 13.4-86.6, 21.1 78.9, 87.7-12.3 and 100 0 the values for $10^4.\rho_0$ are 9.410, 0.585, 0.75, 0.73, 0.475 and for $10^2.\alpha$ 0.438, 0.292, 0.234, 0.280, 0.425, resp. (the old Ti values were 0.82 and 0.469). The ρ_0 values were detd. at 0°, the α values between 0° and 100°. The Ti was prepd. by the method of de Boer and Fast (*C. A.* 20, 427; **24,** 2683), the 100% and 87.7% Ti rods were both monocryst. (10 cm. long or more).
B. J. C. VAN DER HOEVEN

Anisotropy of the electrical resistance of mercury crystals. OTTO SCHELL. *Ann. Physik* [5], **6,** 932–56(1930).—Hg crystals were prepd. in an app. that permitted measurement of the elec. resistance of the material at various angles to the principal axis of the crystals. The temp. range was from −40 to −80°. The sp. resistances parallel to, and perpendicular to, the axis at various temp. are tabulated. The changes in the resistance at the m. p. for each case are given: R (liquid)/R (solid; parallel), 4.94; R (liquid)/R (solid; perpendicular), 3.74. These values are compared with other work, both on Hg and on other metals.
WILLIAM E. VAUGHAN

The compound SnSb. W. MORRIS JONES AND E. G. BOWEN. *Nature* **126,** 846–7(1930). Photograms of SnSb show a NaCl type lattice with 4 mols. per unit cell and a_0 6.092 A. U. The at. nos. of the elements are so close that no reflections from the (11) planes appear, as with KCl. The structure persists from 46 to 60% Sn with slight change of the lattice const.
ARTHUR FLEISCHER

Structure of hydrogen sulfide, hydrogen selenide and nitrogen peroxide at liquid-air temperature. L. VEGARD. *Nature* **126,** 916(1930). Solid H_2S and H_2Se are isomorphous, with cubic elementary cell contg. 4 mols. The S and Se are arranged in face centered lattice. If the H atoms are given positions the most probable arrangement of the atoms in a mol. is in a straight line. The most probable space group would be T_h^6 if the mol. is asymmetric, and T_d^6, if it is symmetric. For H_2S, a = 5.76 A. U. ρ = 1.11. For H_2Se, a = 6.10 A. U., ρ = 2.34. Solid NO_2 has cubical structure, but more complicated than the other two. a = 7.77 A. U. and ρ = 1.93, which gives 6 mols. per cell. T_h^6 is considered to be the only possible space group fulfilling the conditions. Also in *Naturwissenschaften* **18,** 1098(1930).
C. E. P. JEFFREYS

Structure of an organic molecular compound. EDUARD HERTEL AND HANS KLEU. *Z. physik. Chem.*, Abt. B, **11,** 59–75(1930). The crystal structure of the mol. compd. acenaphthene + *1,6 dinitro 1,3-xylene* (1:1) was detd. by x-rays. It is a simple monoclinic translation lattice (space group C_{2h}^5), in which the component mols. alternate along the directions of the crystallographic axes. Simple additive relations connect the lattice dimensions of the compd. with those of the components; the vols. are not additive (4.5% expansion). The crystal structure of acenaphthene (cf. Bragg, *C. A.* 16, 2044) is discussed.
L. ONSAGER

Determination of the melting point of chromium with a thermocouple. LUDWIG MATTHES. *Ann. Physik* [5], **7,** 48–53(1930). A thermocouple, consisting of Ir with 10% Rh against Ir with 10% Ru, standardized by a Pt-Pt Rh couple up to 1600°, and by the m. p. of Pt, was used to obtain the cooling curve of Cr from about 2000° to 1400°. By this method the m. p. of pure electrolytic Cr is 1805°.
L. P. H.

Lead in chemistry and pharmacy. I. History and occurrence. G. MALCOLM DYSON. *Pharm. J.* **125,** 286–7(1930). **II. Extraction and properties.** *Ibid* 302–3. Descriptive and historical. **III. The salts of lead.** *Ibid* 386–7.—Prepn. of the oxides of Pb and of white lead in the historic light. **IV. Medicinal and allied aspects of lead.** *Ibid* 406–7(1930).—Occurrence of Pb in drinking water and in foodstuffs, occupational diseases affecting workers in Pb, and uses of Pb compds. in medicine, including "colloidal Pb," a supposed remedy in cancer (cf. *C. A.* **22,** 2984, 3703, 4642).
S. WALDBOTT

Univalent platinum. W. MANCHOT AND G. LEHMANN. *Ber.* **63B,** 2775–82(1930).—By the reduction of $K_2Pt(CN)_4 \cdot 3H_2O$ in 1% soln. by 3% NaHg, a Pt soln. was obtained that showed marked **reducing properties. It reduced** I soln. and $K_3Fe(CN)_6$. The potential against **platinized Pt was in one case** −0.726 and in another −0.783 for 0.32

M soln. The absence of other reducing agents was ensured. This form of Pt may be involved in the catalytic reactions of the metal. GREGG M. EVANS

Univalent palladium. W. MANCHOT AND H. SCHMID. *Ber.* **63B**, 2782–6(1930).—Univalent Pd, prepd. as was the corresponding Pt compd. (cf. preceding abstr.), was found to be a more energetic reducing agent than Pt. The Pd reduces alk. Pb soln., which is not acted upon by the Pt soln. The valence was established both by measurement of evolved H_2 and by titrations. The possibility of similar compds. for other members of the Fe-Pt group is discussed. GREGG M. EVANS

Density and refraction of crystallized ammonium halides. PETER WULFF AND HUGH K. CAMERON. *Z. physik. Chem.*, Abt. B, **10**, 347–67(1930).—Ds. were detd. by a suspension method for NH_4F, 1.0092, NH_4Cl, 1.5274, NH_4Br, 2.429, NH_4I, 2.5142. For the same salts values for n_D^{25} were measured as 1.3147–60, 1.63851, 1.71239 and 1.70070, resp. The NH_4 ion and the alkali ions were compared. L. P. HALL

The significance of Boedeker's adsorption equation. LOTHAR WÖHLER AND WILH. WENZEL. *Kolloid-Z.* **53**, 273–88(1930).—The adsorption equation usually attributed to Freundlich is credited to Boedeker. The adsorption of acetic, propionic, butyric and valeric acids from aq. soln. by Merck *Carbo animalis pro anal.* was studied at 20°, 40°, 60° and 80° over a range of concns. Rise in the no. of C atoms increases the adsorption. Rise in temp. decreases the adsorption; k decreases while n increases. The coeff. n approaches 1 with increasing temp. and increasing dilu. The adsorption of paraffin from hydrocarbon solvents was studied from —14° to 14°. The const. k decreases and n increases with rise in the b. p. of the solvent. The adsorption of Cl from NaCl, IO_3 from KIO_3, and SCN from NH_4SCN at high dilns. at 18° gave values of $n = 1$. ARTHUR FLEISCHER

The size of bubbles and drops in liquids. SIEGFRIED HALBERSTADT AND PAUL H PRAUSNITZ. *Z. angew. Chem.* **43**, 970–7(1930).—Bubbles formed by forcing N_2 through filtering plates, glass capillaries and perforated Pt plates were photographed as they rose through H_2O or Et_2O. Their size varied approx. as the reciprocal of the pressure With different liquids, the size of the bubble is detd. mainly by surface tension, though viscosity may have a certain influence. Liquid drops were formed by forcing one liquid into another through perforations in metal sheets. In the system EtOAc-H_2O the drops are larger than in Et_2O–H_2O. Their size decreases when the pores are made smaller or the surface tension of the outer liquid is increased. J. H. REEDY

Methods of breaking emulsions formed during the process of ether extractions. LESLIE HART. *Chemist Analyst* **20**, No. 1, 14(1931).—Addn. of 2–3 cc. of 25% NaOH, 2–5 cc. of alc., or 1–2 g. of NaCl, or placing the unstoppered funnel in the rings of the steam bath may break the emulsion. W. T. H

Methods of preventing foaming. LESLIE HART. *Chemist Analyst* **20**, No. 1, 9 (1931).—Foaming during steam distn. or during the detn. of water by the Bidwell-Sterling method of xylene distn. is prevented in different cases by adding one of the following: 3–5 g. $NaHSO_4$, 2–5 g. lump rosin, 5 cc. oleic acid, a small piece of paraffin, a little mineral oil, a sol. Ba or Ca salt, or a few drops of amyl alc. W. T. H.

The influence of insoluble powders on the emulsion type. J. F. CARRIÈRE. *Chem. Weekblad* **27**, 638–9(1930).—In an emulsion of 2 liquids with an insol. powder the liquid that wets the emulsifier forms the homogeneous phase. The wetting liquid enters the capillary spaces between the particles and forms a concave surface at each point against the other liquid. There is equil. when the interface is as small as possible, or when the interfaces between the particles have the smallest radius. This is attained when the particles take a slanting position with regard to each other. The result is that the total interface becomes concave toward the liquid that does not wet the particles. The same theory indicates that the other type of emulsion, if formed, is unstable E. SCHOTTE

Colloids. MERVYN V. SARGENT. *Chemist and Druggist* **112**, 613(1930).—A lecture. S. WALDBOTT

The evolution of colloidal molecules. PAUL BARY. *Rev. gén. colloïdes* **8**, 289–300 (1930).—Colloidal materials are chem. compds. possessing mol. chains on the unsatd. extremities of which radicals are adsorbed from the dispersion medium. They can exist in 2 states that are distinguished by their evolution processes and by their degree of solvation. Peptizable colloids for a given temp., pressure and chem. environment at the time of peptization are compds. that tend toward a very weakly polymerized state limited only by the concn. (pos. evolution). If the conditions of temp. and pressure are varied in the dispersion medium the speed of the evolution process is increased or decreased as the case may be. The direction of the process may be changed and the coagulation process favored or congealing to a mass may result (neg. evolution).

Colloids that at ordinary temp. and pressure are in a state of pos. evolution show swelling but can be peptized in several other liquids either spontaneously or by a slight modification of the temp. or the chem. nature of the dispersion medium. Non-swelling colloids that are dispersed by mech. or elec. means are non-evolutive and give rise only to lyophobic colloids. If the non-swelling colloid is formed by chem. action and is subsequently purified by dialysis, etc., it does so in a non-evolutive manner until it finally becomes an inert colloid. Jellies are produced by the mass congealing of evolutive systems; they are transformed into gels on leaving the evolution zone. F. W. LAIRD

Preparation of colloidal gold by the Zsigmondy method. I. Factors that affect the quality of distilled water. Action of traces of hydrogen sulfide. R. WERNICKE AND R. BIRABÉN LOSSON. *Anales asocn. quím. Argentina* 18, 74–97(1930).—Study of conditions under which good, ruby-red aurosols were obtained with formol in alk. media show that distd. H_2O redistd. into Jena flasks, the condenser being a Ag or Jena-glass tube, is unsuitable; the same H_2O kept 24 hrs. in contact with a piece of vulcanized rubber is satisfactory. If a small piece of vulcanized rubber is placed in boiling, twice-distd. H_2O for 3–5 hrs. the H_2O is satisfactory. By repeated treatments the rubber loses its property of activating the H_2O, but recovers it after 24 hrs. H_2O treated by the second or third method does not become opalescent in the second method even after weeks of contact H_2O can be dild. to 5–6 times its vol. without losing its property of giving good aurosols. H_2O kept in contact with unvulcanized rubber becomes opalescent and gives good aurosols; it does not lose this property on boiling; H_2O treated by the second or third method loses this property on boiling 10 hrs. Twice-distd. H_2O, in contact with air, increases in aurosol-forming properties, but prolonged action gives neg. results. The effect of contact with air cannot be attributed to H_2S content. Very good aurosols are obtained by addn. to twice-distd. H_2O, of Na_2S in concn. of 1.6×10^{-6} to 3.7×10^{-8}, the min. concn. being 3×10^{-9}; 4.9×10^{-6} prevented aurosol formation. Addn. of Na_2S or contact with rubber does not cause ordinary distd. H_2O to form aurosols; addn. of Na_2S allows prepn. of very concd. aurosols and large vols. in a single operation. By boiling 30 hrs. in vessels of Pt, quartz or Jena glass, twice-distd. H_2O does not alter its properties but continues unsuitable for making good aurosols unless Na_2S is added. The good results obtained by Zsigmondy can be explained by the presence of H_2S in the air and by the contact of the H_2O with the rubber tubes. E. M. SYMMES

Precipitation and adsorption of small quantities of substances on crystalline precipitates. OTTO HAHN. *Z. angew. Chem.* 43, 871–5(1930); cf. *C. A.* 21, 530, 1408.—Deposition of small quantities of substances with cryst. ppts. is classified into true "pptn." and "adsorption." True "pptn." is independent of the conditions, and is restricted to isomorphous and isodimorphous mixed-crystal formation. Photographs are presented showing isomorphous $BaBr_2$ + Ra(Th X) crystals, and isodimorphous BaCl + Pb(Th B) crystals. "Adsorption" depends on the conditions of pptn. The adsorption of Pb(Th B) by $BaBr_2$, which clearly differs from the above cases of true pptn. is shown in a photograph. The earlier pptn. and adsorption rule of Fajans and Paneth does not describe the process completely. The more recent adsorption law of H. by considering the charge on the ppt., comes nearer the true relation. Data are given for the adsorption of Th B by gypsum, AgBr and HgBr, and Th C″ by AgBr. However, the adsorption law cannot explain the entire process. Adsorption is very often the sum of at least 2 processes, a primary or momentary adsorption, and a secondary or integral adsorption. Primary adsorption is a function of the surface charge of the adsorbent and the valence of the adsorbed ions. Secondary adsorption results from a kind of building up of mols. on the diminished surface and takes place slowly. If the adsorption compd. is easily sol., secondary adsorption is negligible. R. I. R.

Dispersoid synthesis from gold by means of alkaline formaldehyde solutions. II. P. P. VON WEIMARN. *Kolloid-Z.* 53, 352–70(1930); cf. *C. A.* 23, 2868, 5383.—To prep. a stable red Au sol, it is advisable to use freshly redistd. CH_2O. The other reagents must be of reasonable purity. If redistd. CH_2O is used the water may be ordinary distd. or triple-distd. in Au or Pt condensers, and the same red sol obtained. The unreduced Au is present as AuOH and decreases in amt. with decreasing particle size. The stabilizer of the sol prepd. in this manner is a condensation product of the CH_2O. The article is mainly polemical with Zsigmondy and his school (cf. Das kolloide Gold, Calvary, 1, 1172). ARTHUR FLEISCHER

The coagulation of hydrophobe sols by electrolyte mixtures. H. FREUNDLICH AND TAMAMUSHIGUYNA. *Kolloid-Z.* 53, 288–94(1930).—Pos. Graham Fe_2O_3 sol, hydrophobic CuO sol and TiO_2 sol show no ionic antagonism when pptd. by mixts. of K or Li salts. The same results are obtained by adding a bivalent salt before the univalent. This

checks the work of previous investigators. **The first case of ionic antagonism** in a pos. sol was found with an As_2S_3 sol which was made pos. by the addn. of malachite green. For pure salts the coagulation values decrease in the following order, Li, Na, K. A marked ionic antagonism was found especially for the mixts. NaCl + Na_2SO_4, KCl + K_2SO_4, and $MgCl_2$ + $MgSO_4$, if the chloride is added to the sol first. The antagonistic action is greatest for the K salts, decreasing with Na, and least for Li salts. It is greater for Mg salts than for Be salts. If the sulfate is added to the sol before the chloride, the antagonism disappears. For neg. As_2S_3 sols, the coagulation values decrease in the order Li, Na, K, Mg, Ca, Ba and Al. If Li, Na or K chlorides are added first to the neg. sol, the antagonism increases with the series Ca, Ba and Al. If the higher-valence salt is used first, a slight antagonism is shown with the lower valence salt; it disappears with time. ARTHUR FLEISCHER

The clinging of quartz powder in electrolyte mixtures. A. VON BUZÁGH, H. FREUNDLICH AND J. TAMCHYNA. *Kolloid-Z.* **53**, 294–300(1930); cf. *C. A.* **24**, 3413, 3938, 4684 and preceding abstr.—Measurements were made on SiO_2 particles 17.1μ in size in concns. of 12 mg. per 10 cc. in the presence of Al, Ba, Mg, K, Na and Li salts and their mixts. The results are expressed as curves in which the sine of the break angle is plotted against electrolyte concn. The order of the electrolyte addn. made no difference in the results. Cation antagonism is strongest with the Li ion, then Na, and weak with K. The nature of the cation, the oppositely charged ion in this case, is of greater influence than the anion, the ion of like charge. ARTHUR FLEISCHER

The influence of electrolytes on colloidal sulfur. A. BONVARLET. *Rev. gén colloïdes* **8**, 300–9(1930).—The influence of varying amts. of NaCl on colloidal S was detd. A certain amt. of NaCl is necessary for stability but a concn. of 0.54% must not be exceeded. Ba, Cu, Ca, K and Mg, salts cause irreversible pptn., while Na, NH_4 and Li salts cause reversible pptn Observation in the ultramicroscope revealed no coagulation during reversible pptn even though the particles were deprived of their charge (as evidenced by electrophoresis). During irreversible pptn. agglomeration took place and compact masses were formed For a sol of 13.4% S content the stability appears to be optimum at 0.93% NaCl concn when the ratio NaCl/S is 0.07. These sols are unstable toward heat, cold and light but are easily repeptized by shaking. However, air slowly oxidizes them F. W. LAIRD

Effect of hydrogen-ion concentration on the flocculation values of ferric oxide sols. I. FRED. HAZEL AND C. H. SORUM *J. Am. Chem. Soc.* **53**, 49–54(1931).—The stability of colloidal Fe_2O_3 increases with increasing acidity for KCl, KBr, NH_4Cl, $BaCl_2$, K_2CrO_4, KH_2PO_4, $K_3Fe(CN)_6$ and $K_4Fe(CN)_6$. $FeCl_3$ and Al_2Cl_6 hydrolyze to such an extent that the initial p_H of the sol is altered to a const. value. F. G. G

The Hofmeister series and the hydrogen-ion concentration. E. H. BÜCHNER. *Rec. trav. chim.* **49**, 1150–60(1930); cf. *C. A.* **21**, 3515.—The salting out effect of certain anions on a 1% gelatin sol places them in 2 groups according to p_H. The first group salts out only at $p_H < 5$. This contains Cl^-, NO_3^- and Br^- in the order of decreasing power. The second group salts out only at $p_H > 3$. The order of these anions—tartrate, phosphate and citrate—varies according to the p_H of the sol The salts of the second group are more effective than those of the first, 0.5 to 1.0 mol being sufficient to produce opalescence Sulfate ion salts out in both acid and alk soln It is more effective than the ions of the first group in acid soln. and less effective than those of the second group in alk soln Salicylate ion and I^- fail completely to produce opalescence. With hemoglobin in basic soln. the pptg. power increases in the order thiocyanate, tartrate, acetate; Cl^- no effect. In acid soln. the pptg power increases in the order chloride, nitrate, sulfate, acetate-tartrate-thiocyanate. CORNELIA T. SNELL

Steady states at non-living membranes. JAN STRAUB. *Chem. Weekblad* **27**, 672–4(1930).—S.'s hypothesis of maintenance of const. concn. differences at membranes in live organisms by elec. energy from metabolic processes (*C. A.* **23**, 3482) finds support in the fact that equil. is established at non-living membranes by elec energy. (1) A cellophane cup was filled with 0.1 *N* H_2SO_4 and immersed in a beaker contg. the same soln. The soln. was electrolyzed; equil. was established in hrs. (2) The same expt. was repeated with 0.1 *N* NaH_4PO_4. Equil. was established in hrs. (3) A porous pot contg. solid oxalic acid, satd. oxalic acid soln. and 10% LiCl soln. was immersed in a beaker contg. 10% LiCl soln. and marble chips. Equil. was established in 14 days. The word "harmony" is proposed to express a state of dynamic equil., "being a state in which const. differences of mech. pressure, of osmotic pressure, and of elec. potential, of many concns. are in harmony with const. velocities of chem reaction, of diffusion and of current density." W. GORDON ROSE

The constitution of soluble proteins as reversible, dissociable component systems. S. P. L. SØRENSEN. *Kolloid-Z.* **53**, 306–18(1930); cf. *C. A.* **25**, 245.—Systems that are mixts. of proteins, such as plasma or serum, when subjected to sepn. processes vary in behavior according to the procedure chosen. The relation of lipoids to euglobulin in serum and the relation of the lipoid prepd. by pptn. of the serum in the cold by alc. or alc.-ether are reviewed. It is difficult to det the relations between proteins in soln. by analyzing the products obtained by adding a precipitant because the reagent may cause dissocn. or assocn. of proteins or may lead to the formation of compds. with the proteins. The compn. of such a ppt. gives at best a very incomplete explanation of the original combination relations in the soln. There seems to be no doubt that the lipoids in clear serums are combined in some way with the serum proteins. It is not known with certainty if the lipoids are pptd. with the same proteins with which they are combined in the serum. The exact manner of combination is unknown. The old classification principles for proteins should be retained with specification, however, of the method of sepn. and purification. ARTHUR FLEISCHER

The solubility of hydrofluoric acid in benzene and in octane. J. H. SIMONS. *J. Am. Chem. Soc.* **53**, 83–7(1931).—The solubilities of HF in C_6H_6 and in octane were detd. The vapor pressure of HF from benzene soln. shows unusual deviations from Raoult's law. A possible explanation is given. HENRY J. WING

Study of solutions of tartrates in fused calcium chloride hexahydrate. E. DARMOIS AND J. CESSAC. *Compt. rend.* **191**, 1053–5(1930).—By use of the av. cryoscopic const. k_1 detd. by dissolving urea, KCl, NH_4Cl and $CuCl_2$ in fused $CaCl_2.6H_2O$, solns. of Ca, Me and Et tartrates in fused $CaCl_2.6H_2O$ are shown to have a normal mol. wt. However, $[\alpha]$ differs entirely from $[\alpha]$ in aq. solns. and is in accord with the hypothesis of the existence of several isomers that reach equil. very rapidly. A. P. SACHS

Study of nitric acid. VI. Total vapor pressure of solutions of nitrogen dioxide in highly concentrated to absolute nitric acid and their corresponding densities. ALFONS KLEMENC AND JOHANN RUPP. *Z. anorg. allgem. Chem.* **194**, 51–72(1930); cf. *C. A.* **24**, 2765. The d. of the system: HNO_3–NO_2 was detd. at 0°, 12.5° and 25°. At 0°, as NO_2 ranges from 0 to 41%, d. increases from 1.5472 to 1.6727, and then falls gradually to 1.657 at 55% NO_2. At 12.5 and 25° the max. ds. are 1.6508 and 1.6273, resp. At 55% NO_2, 2 liquid phases are in equil., HNO_3 satd. with NO_2 and NO_2 satd. with HNO_3. In the system: HNO_3–H_2O–NO_2, with 19 *N* HNO_3, d. at 0 ranges from 1.4918 at 0% NO_2 to a max. of 1.5256 at 14% NO_2. With 16 *N* HNO_3, d. at 0° ranges from 1.4491 at 0% NO_2 to a max. of 1.4729 at 16% NO_2. These results indicate a compd. of NO_2 with HNO_3. Vapor-pressure curves were detd. for the same systems at the same temps. Henry's law does not apply for the partial tension p_{NO_2}. The soly. of NO_2 is very great in abs. HNO_3, about equal to that of NH_3 in H_2O. The equil. $HNO_3.NO_2 + H_2O \rightleftarrows HNO_3.H_2O + NO_2$ is assumed and must quickly follow temp. changes. The dissocn. of N_2O_4 occurs rather slowly in the system contg. H_2O, but much more rapidly in abs. HNO_3. The partial specific and molar vols. in the system $HNO_3.NO_2$ were detd. H. STOERTZ

Thermodynamic data on metallic sulfates. II. FUSAO ISHIKAWA AND HOSAKU MURAKA. *Bull. Inst. Phys. Chem. Research* (Tokyo) **9**, 781–94 (Abstracts 81 (in English)) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, No. 271–[illegible]1930); cf. *C. A.* **24**, 4689.—The vapor pressures in mm. of Hg of the following systems were measured by a tensimetric method:

Temp.	$CuSO_4.5H_2O$ and satd. soln.	$ZnSO_4.7H_2O$ and satd. soln.	$CdSO_4.8/3H_2O$ and satd. soln.
20	16.99	15.93	15.65
25	22.99	21.17	21.17
30	30.80	27.73	28.44
35	40.63	35.90	37.84
40	53.37	45.68	49.68

The following values are given for 25°: $ZnSO_4.7H_2O + ZnSO_4.6H_2O - 15.38$; $ZnSO_4.6H_2O + ZnSO_4.H_2O$ 13.73; $ZnSO_4.H_2O + ZnSO_4$ 0.006; $CdSO_4.8/3\ H_2O + CdSO_4.H_2O$ 17.00; $CdSO_4.H_2O + CdSO_4$ 0.02. By combining these results with available data the following were calcd.: $Cu + S + 2O_2 = CuSO_4$, $\Delta F_{298} = -156{,}898$ cal., $\Delta H_{298} = -182{,}172$ cal., $S_{CuSO_4} = 29.1$ cal./deg. (25°); $Zn + S + 2O_2 = ZnSO_4$, $\Delta F_{298} = -207{,}038$ cal., $\Delta H_{298} = -231{,}322$ cal., $S_{ZnSO_4} = 34$ cal./deg. (25°); $Cd + S + 2O_2 = CdSO_4$, $\Delta F_{298} = -194{,}712$ cal., $\Delta H_{298} = -219{,}604$ cal., $S_{CdSO_4} = 34$ cal./deg. (25°). J. B. AUSTIN

New investigations concerning alkali alkyls. FR. HEIN AND H. SCHRAMM. *Z.*

physik. Chem., Abt. A, **151**, 234–56(1930).—Earlier investigations concerning the nature of alkali alkyls, as NaEt, KEt, etc. (cf. *C. A.* **19**, 1080), have established the conception of these substances as salts. In continuing, a cryoscopic investigation was made of the soln. state, or, as far as permitted, the soly. of $ZnEt_2$ solvates of the alkali metal alkyls in benzene. LiEt in C_6H_6 is assocd. 6 to 7 fold, which may be traced to its polar character. The $ZnEt_2$ solvate of LiEt aggregates to higher complexity. The investigation of $ZnEt_2$ solvate of NaEt, KEt and RbE indicated that these are likewise assocd. in C_6H_6. The solns. of the pure monosolvates may be represented by $[MeC_6H_5{\cdot}Zn(C_2H_5)_2]_2$. It is detd. by the method of Barger-Rast (cf. *C. A.* **16**, 519) that NaEt is monomolecular in its dil. non-conducting $ZnEt_2$ soln. The cond. of NaEt-$ZnEt_2$ solns. in C_6H_6, as well as the viscosity, decreases with diln. The electrochem. nature of RbEt is confirmed by detn. of the cond of its $ZnEt_2$ soln. It possesses the most decided salt character of all the alkali metal alkyls investigated. ALLEN S. SMITH

The cryoscopy of paraldehyde in solutions of sodium chloride and barium chloride. F. BOURION AND E. ROUYER. *Compt. rend.* **191**, 1062–4(1930).—The parameter K, for 0.5 and 1.225 *M* NaCl = 23.30 and 31.64, resp.; ΔC = 1.721° and 4.310°, resp. The paraldehyde $(C_2H_4O)_3$ is more or less polymerized. The greater the concn., the less is the mol. wt. An equil exists exclusively between the simple and triple mols. K, for 0.25 and 0.6125 *M* $BaCl_2$ solns. = 22.44 and 28.60, resp.; ΔC = 1.195° and 3.056°, resp. There is no depolymerization and $BaCl_2$ stabilizes the paraldehyde. M. E. L.

Equilibria in osmotic systems in which forces act. I. F. A. H. SCHREINEMAKERS. *Proc. Acad. Sci. Amsterdam* **33**, 820–6(1930).—The first section of a thermodynamic discussion of osmotic equilibria in systems in which there exist in the membrane forces capable of driving one or more substances in one direction or another J. B. AUSTIN

Associations in solution. JAKOB MEISENHEIMER AND OSKAR DORNER. *Ann.* 482, 130–60(1930).—The assocn. of a large no. of simple org. substances, representing many different types of compds dissolved in $PhNO_2$, dioxan and C_6H_6, was detd. by the cryoscopic method. The factor of assocn. increases linearly with the concn. of the soln. and this is regarded as the general course of assocn. The same result is also reached theoretically from kinetic considerations. In certain instances, however such as in a soln. of BzOH in $PhNO_2$, the assocn. factor at first increases rapidly with the concn. and later more slowly. This behavior is due to a special type of assocn leading to the formation of new double or triple mols. in accordance with the law of mass action. The curve obtained is never simple, because the general assocn. process is always superimposed on the special assocn. The assocn. of mixed mols. was also studied. The assocn. of HCl with H_2O, a series of alcs., Et_2O and Me_2CO was followed by prepg. solns. of the components in $PhNO_2$ or in dioxan and detg. the alteration in the f. p. on mixing. HCl assoc. strongly with H_2O and a series of alcs. examd. assoc. to a smaller extent. Those substances that show the greatest sp. assocn. of their own mols. also assoc. most strongly with HCl and the order of the tendency to assoc. with HCl is the same for the series of alcs., in both solvents. Me_2CO assocs. strongly and Ph_2CO weakly with HCl and in general assocn. is less with aromatic compds. In a few cases no change of f. p. occurs on mixing the solns. and in other instances a very slight further lowering takes place. The nature of the force involved in mol. assocn. is discussed and it is pointed out that the assocn of HCl with H_2O does not depend on the no. of single H_2O mols. but on the no. of assocd. H_2O complexes. The degree of sp. assocn. of the solute depends not on the dielec. const of the solvent but on the extent of solvation of the solute in the particular solvent. C. J. WEST

Recalculations of the first dissociation constant of phosphoric acid in aqueous solution at 18°, and incidental determination of the activity coefficients of the undissociated acid molecules. JOSEPH W. H. LUGG. *J. Am. Chem. Soc.* **53**, 1–8(1931).—pK_1 at infinite diln. has been assigned the value 2.09. An approx. equation for the activity coeff. of the undissocd. fraction in pure dil. aq. solns. of H_3PO_4 at 18° is $p\gamma_{H_3PO_4} = -1.8\mu$ where μ is calcd. from the equiv. ion concn. FREDERICK G. GERMUTH

Electrical conductivity of solutions of potassium perrhenate. N. A. PUSHIN AND P. S. TUTUNDŽIĆ. *Z. anorg. allgem. Chem.* **193**, 420–4(1930).—Cond. measurements were made at 18, 25, 30 and 40° on solns. ranging in concn. from 0.04 to 0.0005 *M*. The results include specific and mol. cond., ion mobility (ReO'_4) and degree of dissocn. Mol. cond. at infinite diln., obtained by graphic extrapolation, was found to be 111.5 at 18°, 125.7 at 25°, 141.8 at 30° and 169 at 40°. Specific cond. × 10^6 ranges at 18° from 1923 at a concn. of 0.02 *M* to 55 at a concn. of 0.0005 *M*; at 25° from 2248 at 0.02 *M* to 124 at 0.001 *M*; at 30° from 2510 at 0.02 *M* to 140 at 0.001 *M*; and at 40° from 2976 at 0.02 *M* to 167 at 0.001 *M*. At 0.02 *M* $KReO_4$ is 86% dissocd. at 18°,

89% at 25° and 30°, and 88% at 40°, while at 0.001 *M* it is 96.8% dissocd. at 18°, 98.6% at 25° and 99% at 30° and 40°. H. STOERTZ

Mobility of iron-containing ions. III. The complex ions of the salts $Na_3[Fe(CN)_5OH_2]$ and $Na_2[Fe(CN)_5OH_2]$. FRANK HÖLZL. *Monatsh.* 56, 253–60(1930); cf. *C. A.* 25, 245.—The acid character of the salts is established by both cond. and titration methods. These ions carry an "uncoördinated" mol. of H_2O which, with the acid H, forms hydroxonium salts $Na_3H_2O{\cdot}H[Fe(CN)_5OH]$ and $Na_2H_2O{\cdot}H[Fe(CN)_5OH]$. These with NaOH form salts contg. 4 and 3 Na atoms, resp. GREGG M. EVANS

The thermodynamic properties of molten solutions of lead chloride in lead bromide. E. J. SALSTROM AND J. H. HILDEBRAND. *J. Am. Chem. Soc.* 52, 4641–50(1930).—A reversible and reproducible Br electrode was devised. The ds. at 500° of $PbBr_2$ and $PbCl_2$ and of their solns. were detd. The molal vols. are additive. The free energy changes of molten $PbBr_2$ on diln. with $PbCl_2$ were also detd. The free energy of formation in cals. of pure molten $PbBr_2$ is $-69270 + 28t$ between 450° and 580°. J. B. AUSTIN

The thermodynamic properties of solutions of molten lead chloride and zinc chloride. A. WACHTER AND J. H. HILDEBRAND. *J. Am. Chem. Soc.* 52, 4655–61(1930).; cf. preceding abstr.—The e. m. f. of reversible cells with metal and Cl_2 electrodes and fused salt electrolytes was measured in the range 500° to 600°. At 500° the free energies and heats of formation, resp., are: molten $PbCl_2$, —58,750 cals., —81,100 cals.; molten $ZnCl_2$, —72,550 cals., —97,300 cals. The free energy change upon diln. of $PbCl_2$ with $ZnCl_2$ was also calcd. Neither the assumption of no ionization nor that of complete ionization of both salts accounts for the observed values. The d. of molten $PbCl_2$ in this range is $4.947–0.00164\ (t-500)$; that of molten $PbCl_2$, $2.424–0.00046\ (t-500)$. A 50 mol. percent soln. has a d. slightly less than the additive value. J. B. AUSTIN

The activity coefficient of copper iodate in aqueous salt solutions. BEN H. PATERSON AND EARL L. MEYERS. *J. Am. Chem. Soc.* 52, 4853–7(1930).—Activity coeff. of $Cu(IO_3)_2$, measured by the soly. method in aq. solns. of the chlorides and sulfates of K and Mg, show deviations from the Debye-Hückel limiting law similar to those found for other valence types by La Mer and Goldman (*C. A.* 23, 5085). The soly. of $Cu(IO_3)_2$ in water is 0.003693 mols. per l. at 25°. OSCAR T. QUIMBY

A potentiometric study of acid-base titration systems in the very strongly acid solvent formic acid. LOUIS P. HAMMETT AND NICHOLAS DIETZ, JR. *J. Am. Chem. Soc.* 52, 4795–4807(1930).—Titrations in HCOOH with $C_6H_5SO_3H$ were made with $NaHCO_2$, $(C_6H_5)_2COH$, and urea, which acted as strong bases. Gold electrodes were used and the comparison electrode was *p*-benzoquinhydrone in HCOOH satd. with $NaO_2SC_6H_4$ plus 0.098 *M* $NaHCO_2$. L. P. HALL

The strength of organic bases in glacial acetic acid solution. NORRIS F. HALL. *J. Am. Chem. Soc.* 52, 5115–28(1930); cf. *C. A.* 24, 2017.—A large no. of org. bases were titrated with $HClO_4$ in glacial AcOH soln. It is shown that the relative strengths of the bases in AcOH and H_2O are nearly proportional and that it is possible to det. in AcOH the "H_2O strength" of certain bases which cannot be studied in H_2O. A large part of the published data on the strength of bases in H_2O has been surveyed, and the values cor. to 25° where necessary in accordance with the new detns. of the temp. coeff. of pK_B for bases of different strengths. H. W. LEAHY

Chemical reaction between metallic magnesium and aqueous chloride solutions. ICHIRO IITAKA. *Proc. Imp Acad.* (Japan) 6, 363–6(1930).—Mg reacts with aq. solns. of NaCl, KCl, $BaCl_2$, $SrCl_2$, $CaCl_2$, $MgCl_2$, $AlCl_3$, $MnCl_2$, $ZnCl_2$, etc., but not with solns. of nitrates, sulfates, phosphates and acetates. Solns. freed from O_2, N_2 and CO_2 also react showing that these gases have no part in the reaction. The reaction velocity of Li with HNO_3, NaOH, HCl, H_2SO_4, AcOH and H_3BO_3 is given in the form of curves. Possible equations are given. Full details will be given in the *J. Iron Steel Inst. Japan.* C. J. WEST

Slow and induced oxidation of potassium oxalate, sodium nitrite and sodium sulfite. SACHINDRA NATH CHAKRAVARTI AND N. R. DHAR. *J. Phys. Chem.* 34, 2749–60(1930).—In previous work (*C. A.* 20, 2935) it was shown that $K_2C_2O_4$ and $NaNO_2$ are not oxidized appreciably by passing air for 5.5 hrs. at 30° through their solns. in the presence of $Fe(OH)_3$, $Ce_2O_3{\cdot}6H_2O$, and Na_2SO_3. The expts. are repeated with *freshly pptd.* $Fe(OH)_3$ and $Ce_2O_3{\cdot}6H_2O$ and aq. solns. of Na_2SO_3. The concns. of the acceptor and inductor as well as the time of passing air are varied. In addn. the oxidation of Na_3PO_3 in the presence of Na_2SO_3 is studied. In the presence of $Ce_2O_3{\cdot}6H_2O$ neither $K_2C_2O_4$ nor $NaNO_2$ can be oxidized, but both are oxidized easily by passing air at 30° in the presence of $Fe(OH)_3$ and Na_2SO_3. The oxidation of $NaNO_2$ is much greater when the $Fe(OH)_3$ is prepd. in the soln. contg. the $NaNO_2$ than when prepd. separately.

This is explained on the assumption that an easily oxidizable complex is formed between $FeSO_4$ and $NaNO_2$. In all cases oxidation increased with increasing concns. of inductor and acceptor, and also with time. A peroxide type of compd. is formed in every case (except with Na_3PO_3) which liberates I from an acid soln. of KI, and which depends upon the concn. of the acceptor only. Colloidal complexes prevent investigation of the oxidation of Na_3PO_3 in the presence of $Fe(OH)_3$ and $Ce_2O_3 \cdot 6H_2O$.
H. W. Leahy

The sorption of hydrogen sulfide by potassium benzenesulfonate. II. Willy Lange and Gerhard Lewin. *Ber.* **63B**, 2954–9(1930); cf. *C. A.* **25**, 21.—The integral heat of reaction, when 1 mol. of $(KO_3SPh)_4 \cdot H_2S$ (I) is formed from H_2S and aged KO_3SPh (II), is 10,000 ± 200 cal. The differential heat of this reaction is less for fused than for aged II. The sorption of H_2S obeys the equation: $c = (ap/kRT)/(1 + p/kRT)$, in which c is the no. mols. H_2S taken up per mol. II under pressure p and temp. T, k is the equil. const. and a is the limiting value of c, namely, 0.25. The exptl. isotherm at 0° gives $a/kRT = 0.00437$ if p is in mm. Hg. The sorption isobar also follows the above equation if the influence of T on k is detd. by the reaction isochore. O. T. Q.

The combustion of carbon disulfide with oxygen. H. W. Thompson. *Z. physik Chem.*, Abt. B, **10**, 273–95(1930).—The reaction between CS_2 and O with vol. relations of 1:3 was followed manometrically over a range of temps. and pressures. Below 140° the thermal reaction was very slow, but above this temp. there were definite pressure limits which became wider with increasing temp. The similarity of this reaction to that of H and O is stressed, as is also the importance of the effects of walls
L. P. Hall

Oxidation of carbon monoxide by dissociated water vapor. G. I. Lavin and W. E. Jackson. *J. Am. Chem. Soc.* **53**, 383–4(1931).—Harteck and Kopsch (*C. A.* **24**, 5612) showed that atomic O, from a discharge tube, has very little effect on CO. It is now shown that dissocd. H_2O vapor causes oxidation of CO to CO_2; the oxidation in H and K.'s expts. is due to the presence of a small quantity of H_2O. C. J. West

The indanthrene fusion. III. Indanthrene fusion in presence of phenol. T. Maki. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 456–60(1930) (in German); cf. *C. A.* **24**, 2366; Japan. Patent 84,373.—Addn. of phenols or naphthols to the fusion mass selectively accelerates indanthrene over alizarin formation. Fusing a mixt. of 4.2 g. PhOH 40 g. KOH (79%), and 10 g. 2-aminoanthraquinone at 180°, for 60 min., gave 51.5%, the max. obtainable yield of indanthrene. A straight fusion, under optimum conditions, yielded no more than 18%. **IV. Influence of temperature in fusions with phenol present.** *Ibid* 461–3(1930).—No temp. variation raised the yield above the max. 51.5%. Fusion at 180° was completed in 60 min., at 210° in 15 min. Higher temps. than 210° increased the decompn. velocity unduly. K. H. Engel

The reactivity of the halogen derivatives of cyclohexane. B. V. Tronov and L. V. Ladigina. *Ber.* **63B**, 3060–7(1930).—A detn. was made of the relative reaction velocity of cyclohexyl chloride, bromide and iodide with CH_3ONa, pyridine and piperidine. The compds. in equimolar amts. interact at 17–19° for equal time intervals. The liberated halide is detd. gravimetrically as the Ag salt. The compds. studied rank next to the tertiary halohydrocarbons in reaction velocity. The mechanism of reaction is considered on the basis of the electron and polarity theories. B. A. S.

The solution of metals in acids. Gerhard Walpert. *Z. physik. Chem.*, Abt. A, **151**, 219–33(1930).—The soln. of metals in acids after the addn. of salts, acids and high-mol. substances is investigated. HCl reduces the potential and the soln. velocity of iron in 8 *N* H_2SO_4. The influence of the addn. does not follow immediately and no change is observed in the gas evolution in the first few minutes. A const. gas evolution and potential are obtained after 30 to 40 min. H_2SO_4 added to 8 *N* HCl reduces the soln. velocity of iron but not in the same measure as in the reverse order. The sequence of the reduction of soln. velocity of iron in concd. H_2SO_4 through salts is I > Br > Cl. In dil. solns. the influence of salts is small. The aliphatic acids reduce the reaction velocity in the order: formic, acetic, propionic, butyric. High-mol. substances, such as gelatin and methyl violet, reduce the reaction velocity to a large extent. The results are analogous for Cr, Zn and Cd, only salts increasing the soln. velocity. The observations may be traced to the adsorption of foreign substances. It follows that the primary process in the soln. of metals is likewise an adsorption of ions.
Allen S. Smith

An attempt to measure the velocity of dissociation of nitrogen tetroxide by the method of sound waves. Geo. B. Kistiakowsky and Wm. T. Richards. *J. Am. Chem. Soc.* **52**, 4661–71(1930).—The velocity of sound at 25° in N_2O_4 was investigated at frequencies from 10 to 80 kilocycles and pressures from 760 to 140 mm. by the use

of the magnetostriction oscillator developed by Pierce. It is independent of the frequency. Calcns. indicate that the theoretical velocity of decompn. and the no. of triple collisions have values close to those calcd. from the min. velocity const. defined exptly. Preliminary detns. of the absorption of sound in N_2O_4 are given. A. S. S.

The effect of neutral salts on reaction velocities in alcoholic solutions. ANTON KAILAN AND ADOLF IRRESBERGER. *Monatsh.* **56**, 428–46(1930).—The esterification of benzoic acid in alc. soln. with HCl as a catalyst is retarded by the addn. of 0.1–1 mol /l. of LiCl, $CaCl_2$ or $HgCl_2$, provided that the water content of the alc. is very small (0.05 *M.*). However, in alc. contg. approx. 1 mol./l. of water the same reaction is accelerated by addn. of the salts named, except $HgCl_2$ added in concn. $^1/_2$ mol. or less. The retardation is attributed to viscosity, the acceleration to hydration.

L. ONSAGER

Determination of the melting point of platinum alloys. LUDWIG MÜLLER. *Ann. Physik* [5], **7**, 9–47(1930).— For the measurement of temps. above 1500° a photoelec. cell was used with a wave filter. Standardizations were made with pure metals similar in kind and m. p. to the alloy under investigation. The liquidus curves (freezing point) were detd. for the systems Pt–Rh, Pt–Ir, Pt–W (up to 51.4 at. % W), Pt–Cr (up to 61.7% at. % Cr). For detn. of elec. cond. and temp. coeffs. wires were made of Pt with 3 and 5% Cr and 5 and 10% W, which were homogenized at 800°. Photomicrographs of Pt alloys with 50% Rh, Ir and W, 10% W and Cr, also 30% Cr were made. These studies indicated the formation of mixed crystals for Pt alloys contg. from 0 to 100% Rh or Ir, from 0 to at least 50% W, and from 0 to 10 or perhaps 30% Cr.

L. P. HALL

Special properties of eutectic and eutectoid mixtures in the binary metal systems. ...DAU *Z. anorg. allgem. Chem.* **194**, 1–37(1930).—Annealed eutectic mixts. of ...Pb, Sb, Sn–Zn, Au–Zn and Au–Cd and annealed C contg. eutectoid steels possess greater hardness and elec. resistance and lower temp. coeff. and cond. than the neighboring mixts. For this reason the phys. and mech. properties of eutectics and eutectoids cannot be brought into a scheme of straight-line diagrams, as can be done for the properties of alloys that consist of mech. mixts. of phases. On the property diagrams, eutectics and eutectoids take positions of relative maxima (hardness, elec resistance) or relative minima (cond., temp. coeff.) or, in general, the intersecting point of 2 lines that represent the properties of alloys on each side of the eutectic or eutectoid. This condition applies to all isotherms up to the m. p. of the eutectic or to the transition into solid soln. by the eutectoid and reappears on cooling. For coalescence to occur on heating, the eutectic mixt., an excess of one phase of which the eutectic is comprised is necessary.

H. STOERTZ

Does a middle horizontal part between two eutectic points exist on the fusion diagrams of binary systems? N. A. PUSHIN AND I. I. RIKOVSKII. *Z. physik. Chem.*, Abt. A, **151**, 257–68(1930).—R. Kremann *et al.* (cf. *C. A.* **12**, 1524) have worked out many fusion diagrams of binary systems that indicate chem. compds. between the components. The authors det. whether such diagrams exist. The investigation of the systems *m*-dinitrobenzene–*o*-phenylenediamine, *m*-dinitrobenzene–*m*-phenylenediamine, benzamide–*m*-nitrophenol, benzamide–*p*-nitrosodimethylaniline, benzophenone–picric acid by means of thermal analysis indicates that the middle horizontal branches which are given on the diagrams of Kremann, do not exist. In the five systems the diagram of state is expressed by two branches that meet at a single eutectic point. The system naphthalene–*m*-dinitrobenzene contains no horizontal branch but is characterized by a eutectic and a transformation point. The components form an equimol compd. It is concluded that middle horizontal branches between two eutectic points seldom exist on a fusion diagram since in none of the cases investigated was it confirmed

ALLEN S. SMITH

Electrochemical investigations of aluminum and alloys of aluminum with mercury. H. GERDING. *J. physik. Chem.*, Abt. A, **115**, 190–218(1930).—The complete binary system Al–Hg is detd. by means of potential measurements of Al and Al–Hg alloys in acetylacetone solns. The system contains no compds. A region of two phases, a liquid and a solid, extends from 0.8 to 99.97 atomic % Hg. The potentials of Al amalgams are more neg. than the potential of Al in solns. of Al amalgam and acetylacetone. The potential increases up to 0.35% Hg and is const. in the region of the two phases. The potential difference between an amalgam with two phases and the extrapolated potential of the "theoretical Al" amts. to 130 mv. Amalgams with 0.2% or more Hg evolve H in the soln. used and form Al acetylacetonate. No H is evolved in pure acetylacetone soln. at first and the potential is slightly neg. The difference between the pure liquid and a satd. soln. of Al acetylacetonate in acetylacetone is probably the

result of a difference of the charge on the Al ion. The oxide-film theory cannot explain the electrochem. behavior of Al and the Al–Hg alloys in the soln. The normal potential of the "theoretical Al" is 1.47 v. in $AlCl_3$ and 1.43 v. in $Al_2(SO_4)_3$ soln. in water.
ALLEN S. SMITH

Rates and temperature coefficients of the catalytic decomposition of ammonia over molybdenum, tungsten and promoted iron. C. H. KUNSMAN, E. S. LAMAR AND W EDWARDS DEMING. *Phil. Mag.* 10, 1015–37(1930).—A formula for the "true heat of activation," Q, is developed in terms of the temp. coeff., E, and the heats of desorption of the reactant and products. $E = Q - \lambda_0 + \sum_0^n \lambda_i \sigma_i$, in which $\lambda_0, \lambda_1 \ldots \lambda_n$ are the heats of desorption for the reactant and n products and $\sigma_0, \sigma_1, \ldots \sigma_n$ are the fractions of the surface covered by the reactant and the n products. NH_3 was decomposed on Mo and on W in the form of filaments and also promoted Fe catalysts. The change in pressure with time was detd. The temp. of the catalysts was detd and kept const. during an expt. by means of a Wheatstone bridge arrangement. Temp. measurements were made with pyrometer, thermocouple and by means of the temp coeff. of the resistance of W and Mo. It is concluded that the absorption of N from the gas phase is negligible and that the surface is covered with H and NH_2 during a run. The heat of activation and the heat of desorption of NH_2 less that of H are computed and tabulated. The heats of activation vary from 24,500 for used Mo at high temp. to 45,600 for one of the Fe catalysts.
WILLIAM E VAUGHAN

Dependence of detonating gas catalysis upon the quantity of catalyst. C. KRAUSE *Z. anorg. allgem. Chem.* 194, 73–88(1930).—In a heterogeneous catalytic gas reaction, such as takes place in detonating gas ($2H_2 + O_2$), the equil. depends, among other factors, upon the quantity of catalyst. The silent union of H_2 and O_2 was studied in the presence of catalysts that adsorb O_2 markedly, such as Ag, or catalysts that act chiefly chemically, in which the adsorption is retarded by the formation of intermediate compds. Catalysis with Sb, Ni, Cu and Ni and Cu oxides involves alternate oxidation and reduction. With Ag having a particle size from 0.05 to 1.0 mm., the reaction takes place at a lower temp. the greater the amount of catalyst present. With 2 g. of Ag, the reaction was 38.7% completed at 302°, with 4 g. of Ag, 38% completed at 265° and 84% at 315°; with 16 g. of Ag, 31.2% at 206°, and with 62 g. of Ag, 100% completed at 190°. The heat of activation of the Ag was found to be 12.12–12.98 kg.-cal. For the reaction with Sb as catalyst, "Kahlbaum" metal was finely powdered, its particle size being 0.02–0.2 mm. In this case variation in quantity of catalyst was without effect, indicating no adsorption of either H or O. The heat of activation was found to be 13.5 kg.-cal. With Ni, the temp. at which 100% reaction was brought about with 2 g. was 286°, with 4 g. 257°, with 8 g. 247° and with 16 g. 191°. The heat of activation was found to be 18.3 kg.-cal. NiO gave 100% reaction with 4 g. at 230°, with 8 g. at 215°, with 16 g. at 223° and with 64 g. at 247°. With Cu, 100% reduction occurred with 8 g. at 313°, with 16 g. at 350° and with 64 g. at 310°. The heat of activation with 16 g. was 17.6 kg.-cal. With CuO, 100% reaction was obtained with 4 g. at 204°, with 8 g. at 258°, with 16 g. at 265° and with 32 g. at 272°.
H. STOLTZE

The catalysis of autoxidation: antioxygenic and pro-oxygenic action of iron and its compounds. CHARLES DUFRAISSE AND RAYMOND HORCLOIS. *Compt. rend.* 191, 1126–8 (1930); cf. *C. A.* 18, 2138, 2635, 3134; 20, 2443, 3625.—The wide distribution of Fe in nature and its presence in respiratory pigments of higher animals make study of the catalytic activity of Fe important. Some authorities consider Fe exclusively a positive catalyst for autoxidation (cf., however, Berl and Winnacker, *C. A.* 24, 4374). Expts. were made on the following autoxidizable substances: acrolein, PhCHO, furfural, styrolene, turpentine and Na_2SO_3 in slightly acid or slightly alk. aq. soln. The following Fe compds. were used as catalysts: in the ratio 1:100—metallic Fe, anhyd. FeO, $Fe(OH)_2$, anhyd. $FeCl_2$, anhyd. $FeCl_3$, FeI_2, anhyd. $FeSO_4$, ferric alum, FeC_2O_4, $K_4Fe(CN)_6$, $K_3Fe(CN)_6$, Prussian blue, French blue; in the ratio 1:50—ferric acetylacetonate; in the ratio 1:10 (corresponding to a concn. of Fe of the order of 3.5 in 10,000)—oxyhemoglobin, methemoglobin, carboxyhemoglobin; in the ratio 1:25 (corresponding to a concn. of Fe of the order of 3.5 in 1000)—hematin, α-chlorohemin, β-chlorohemin, β-bromohemin, di-Me ester of α-chlorohemin. In common with other elements, the catalytic activity of Fe varies in intensity and in sign, according to its chem. form and the nature of the autoxidizable materials with which it is in contact. The non-ferruginous part of the catalyst often exerts a detg. influence. Thus $FeCl_2$ accelerates, while FeI_2 retards, the autoxidation of PhCHO and of acrolein. Ferric alum is strongly

-oxygenic, while ferric acetylacetonate is clearly antioxygenic toward Na_2SO_3. With re complex catalysts, especially with the large mols. like that of oxyhemoglobin, non-ferruginous portion influences the catalyst even so far as to cause a reversal the direction of the action. The following Fe compds. have an antioxygenic action:) for furfural; $Fe(OH)_3$ for Na_2SO_3 in slightly alk. soln.; $FeCl_3$ for PhCHO and for rfural; ferric acetylacetonate for Na_2SO_3 in weakly acid or weakly alk. soln. and for rfural; oxyhemoglobin, carboxyhemoglobin and methemoglobin for furfural and to maller extent for acrolein and Na_2SO_3; α-chlorohemin for furfural; β-chlorohemin, matin, di-Me ester of α-chlorohemin, and β-bromohemin for furfural, acrolein and to maller extent for Na_2SO_3 and PhCHO. These expts. show that Fe has an anti- nic as well as a pro-oxygenic action, and that the "relationship of inverse catalyses" plies to ferruginous catalysts as well as to others. LOUISE KELLEY

The **reaction between methanol and steam as an example of heterogeneous catalys.** J. A. CHRISTIANSEN AND JOHN R. HUFFMAN. *Z. physik. Chem.*, Abt. A, **151**, 2(1930).—A kinetic investigation is reported of the reaction $CH_3OH + H_2O = 3\ H_2$ catalyzed by Cu at temps. of 190° to 250°. In all the expts. about 0.1 tom of Cu with varying addns. of $Mg(OH)_2$ was used. The conclusions were from expts. made with a ratio of 0.7 atom Mg/1 atom Cu. The catalyzer de- activity with time but can be reactivated to a known max. value by treatment The activity decreases with increased ratio of Mg to Cu. The reaction ve- can be expressed by $(\sqrt{[M]}/2v) = I\ (1 + \varphi.[H_2] + \varphi[H_2]\ [CO_2]/[M])$, where indication of the activity of the catalyst, φ is a function of the partial pressure and H_2O, and $[M]$, $[H_2]$ and $[CO_2]$ are partial pressures. The initial velocity proportional to $\sqrt{[M]}$, whereas H_2 apparently arrests the reaction. The of CO_2 and H_2O on the velocity is small. The temp. effect is large and its to the const. $1/I$ may be expressed by $-\log_{10} I = -(6470/T) + 12.19$.

ALLEN S. SMITH

The **catalytic preparation of 2,4-diaminophenol.** W. E. BRADT. *J. Phys. Chem.* 34, 1(1930).—An abs.-alc. soln. of 2,4-$(O_2N)_2C_6H_3OH$ (I) was reduced to 2,4- H_3OH (II) in the presence of a Ni catalyst under 500 lbs. of H pressure. The of II was obtained at 96°. Increasing the time of reduction beyond 2 hrs. a slight increase in the yield of II. Variation of the concn. of I (when the Ni to I was 1:5) caused a max. yield of 91.5% at a concn. of 5 g. in 20 cc. of sol- When the ratio of Ni to I was 2:5, variation of the concn. of I gave a max. 97%, from 2.5 g. of I in 20 cc. of solvent. The latter ratio of g. of catalyst to g. of I caused an increase in the yield of II at all concns. investigated. Abs. EtOH at room temp. over $CuSO_4$ gave higher yields than any other solvent The Ni catalyst was reduced from $NiCO_3$ at 288°. H. W. LEAHY

Adsorption and promoter action in catalysis. A. C. ROBERTSON. *J. Am. Chem.* 53, 3(1931).—R. does not agree with Taylor that the result of Elissafoff's 1, 9, 3015) is an example of adsorption in catalysis. The glass wool prob- Cu from soln. as E. says but not as $CuSO_4$; the Cu probably forms a upon the surface of the glass wool and then solid CuO_2. C. J. WEST

Reactions at the surface of hot metallic filaments. B. S. SRIKANTAN. *Rec. trav.* 49, 946–9(1930); cf. *C. A.* **24**, 2036, 5584.—A general discussion. A study of the reaction of CO_2 and H_2 at various surfaces indicates that a good catalyst sup- the necessary energy of activation at a lower temp. than a poor catalyst, and at the same temp. enables the reactants to reach an active state with a smaller quantity of energy. CORNELIA T. SNELL

I. The **specific heats of thallium, calcium and magnesium measured to 10° absolute.** II **The entropy and chemical constants of magnesium from spectroscopic data.** F. G. KEYES AND J. V. VAUGHEN. *J. Am. Chem. Soc.* **52**, 4686–99(1930).—By use of a vacuum calorimeter and Pb resistance thermometer (*C. A.* **23**, 3609) the sp. heats of Tl, Ca, and Ca were detd. between 10° and 200° abs. and their Debye functions studied. The entropies were calcd. as 15.51, 9.72 and 7.76, resp. The vapor pressure constant of Mg was calcd. as 0.443 ± 0.1 and the entropy of Mg vapor as 35.29 at 25°. L. P. HALL

The calculation **of free energy from spectroscopic data.** W. F. GIAUQUE. *J. Am. Chem. Soc.* 52, 4808–15(1930).—Preparatory to the presentation of thermodynamic properties from spectroscopic data, methods and equations for the exact calcn. of free energy, entropy, etc., for **gases** are discussed. L. P. HALL

The entropy **of hydrogen and the third law of thermodynamics. The free energy** and dissociation **of hydrogen.** W. F. GIAUQUE. *J. Am. Chem. Soc.* **52**, 4816–3

(1930).—The relative amts. of ortho- and para-H are calcd. from 0° to 298° abs. for equil. conditions. Energy contents and heat capacities for the 2 rotational states and mixts. are obtained from certain equations (cf. preceding abstract). Values for the free energy of the reaction $H_2 = 2$ H, equil. consts. and percentage dissocn. up to 5000°K. are calcd. from band-spectrum data and agree well with those experimentally detd. by others. L. P. HALL

Calculation of heat of activation. H. EYRING AND M. POLANYI. *Naturwissenschaften* **18**, 914–5(1930); cf. *C. A.* **24**, 2941.—Application of the theory of London (Sommerfeld Festschrift Leipzig 1928, 104) on the reaction H + H_2 (para) = H_2 (ortho) + H (all atoms being assumed to be on one line) does not give a satisfactory result. The activation heat is actually between 4 and 8 kg.-cal. (Farkas, *C. A.* **25**, 32) more than the value calcd. from London's equation. By taking into account Coulomb members of the energy equation and the influence of the 2 outer atoms on each other (both factors were left out by L.) it is found that for a symmetrical condition of 3 H atoms in line the energy is a max. By taking the energy of the lowest max. as activation energy and considering the corresponding distances as those of an intermediary condition in the reaction above mentioned, it is found that the H atoms are thereby 0.95 A. U. apart (normal H_2 mol. 0.76 A. U.); the heat of activation is less than 10 kg.-cal The influence of the two outside H atoms on each other makes the original H_2 mol wider. B. J. C. VAN DER HOEVEN

The heat of formation of water. FREDERICK D. ROSSINI. *Proc. Nat. Acad. Sci.* **16**, 694–9(1930).—H_2 and O_2 were burned in a small chamber in a calorimeter and the wt. of H_2O formed was detd. The temp. rise was measured by a Pt resistance thermometer. The temp. rise was then reproduced with a measured elec. input. The av temps. were 25° and 30° in two sets of expts. The heat of formation of 18.0156 g of liquid H_2O at 25° and const. pressure of 1 atm. was 285,775 ± 40 international joules, or 68,313 cal. (15°). Also in *Bur. Standards J. Research* **6**, 1–35(1931). L. P. HALL

Thermal decomposition of nitrous oxide between one and ten atmospheres. N NAGASAKO AND M. VOLMER. *Z. physik Chem.*, Abt. B, **10**, 414–8(1930).—The uni mol. character of the reaction is confirmed. Temp. range is 848–938°. The heat of activation is 53 kg.-cal./mol. WILLIAM E. VAUGHAN

The decomposition of citric acid by sulfuric acid. EDWIN O. WIIG. *J. Am. Chem. Soc.* **52**, 4729–37(1930).—The decompn. of citric acid was found to follow the unimol. rate law. Small quantities of both SO_3 and H_2O have a pronounced inhibitory action on the velocity of decompn. As the concn. of H_2SO_4 increased, the rate increased to a max. which varied with the temp. For a 10° rise in temp. the temp coeff. was approx. 4 and increased regularly as the H_2O content of the H_2SO_4 increased The decompn. is assumed to proceed through the formation of an unstable citric acid – H_2SO_4 mol. complex. The inhibition by H_2O and SO_3 is explained on the basis of Taylor's theory of neg. catalysis. H. W. LEAHY

The effect of sulfur trioxide on the decomposition of oxalic acid by sulfuric acid. EDWIN O. WIIG. *J. Am. Chem. Soc.* **52**, 4737–41(1930); cf. preceding abstr.—The rate of decompn. of oxalic acid by H_2SO_4 mixts. contg. 0–30% free SO_3 showed a max at 14% SO_3 (2.0 molar). The data have been interpreted to indicate that SO_3 is not a pos. catalyst but merely decreases the concn. of H_2O, which is a very powerful inhibitor, the SO_3 being relatively weak. H. W. LEAHY

Inhibition in the decomposition of organic acids by sulfuric acid. EDWIN O. WIIG. *J. Am. Chem. Soc.* **52**, 4742–51(1930); cf. preceding abstrs.—The mechanisms of the above decompns. are discussed. Taylor's theory of neg. catalysis offers the only satisfactory explanation for the effect of inhibitions on the decompn. of org. acids by H_2SO_4 No definite conclusions with respect to the applicability of the chain reaction theory can be made until more data are available. H. W. LEAHY

The decomposition of ethylamine. A unimolecular reaction. H. AUSTIN TAYLOR. *J. Phys. Chem.* **34**, 2761–70(1930).—The decompn. of $EtNH_2$ was shown to be a homogeneous unimol. reaction over the temp. range 500–40° and at pressures of 50–400 mm The energy of activation was detd. to be 43,400 cals. and the value of E/RT of 28.9 was found to be comparable with that of other unimol. reactions. H. W. LEAHY

Thermal and chemical potential. PAUL DROSNE. *Chaleur et ind.* **11**, 465–8 (1930).—A discussion of terminology. S. L. B. ETHERTON

The use of optical data for calculation of activation heat. H. EYRING. *Naturwissenschaften* **18**, 915(1930).—In the calcn. of the H + H_2 (para) = H_2 (ortho) + H reaction it appeared that the Coulomb members of the London energy equation amount approx. to 10% of the whole if the system is in the reaction range. If this is a general rule it will make possible the calcn. of a large no. of chem. reactions when the total

energy of diatomic mols. as a function of the nucleus distance is known from optical consts. (cf. Morse, *C. A.* **23**, 5406). B. J. C. VAN DER HOEVEN

Direct determination of the electron volume. V. POSEJPAL. *Compt. rend.* 191, 1000–2(1930).—P. derives the equation $\sigma/\rho = (\pi/m_H)r^2$, in which σ/ρ is the sp. diffusion coeff. of very hard γ-rays in H, $m_H = 1.662 \times 10^{-24}$ g., and r the radius of the ether corpuscle. For r is obtained the same value which the electromagnetic theory gives for the radius of the electron, thus lending support to the author's theory of a *corpuscular ether* composed of neutrons. FRANK URBAN

Optics of x-ray reflection from crystal faces. IV. Complete spectral diagrams (zone diagrams). H. SEEMANN. *Ann. Physik* [5], 6, 793–824(1930).—A detailed consideration of x-ray optics. C. E. P. JEFFREYS

A relationship between electron interference and soft x-rays. E. RUPP. *Naturwissenschaften* 18, 880(1930).—Vacuum tubes were constructed which made possible measurement of electron diffraction and of the crit. potential of soft x-rays (method of Richardson and Chalklin, *C. A.* 22, 2712), the former with or without variable angle of incidence. When the diffraction curve was measured for (111) face of Ni, angle of incidence $\theta = 10°$, maxima at 66 and at 132 v. were found. On the same surface a measurement of the photoelectrons caused by soft x-rays (electrode circuit of Richardson and Andrews, *C. A.* 24, 5215) gave a relation between i_p/i_t (i_p is photoelectron current, i_t current to Ni crystal) and potential with crit. potentials at 66.5 and 132 v. obviously the same as before. This coincidence is not accidental. The same result is obtained for const. velocity of the rays and variation of θ. A similar coincidence was furthermore found on W and on Cu. Apparently certain crit. potentials for soft x-rays exist which are related to the properties of the crystal lattice. B. J. C. v. D. H.

Interference of x-rays on thin films. HEINZ KIESSIG. *Naturwissenschaften* 18, 847–8(1930).—Reflection curves of thin Ni mirrors for x-rays were studied (Cu K_α line of $\lambda = 1.54$ A. U.). The mirrors were made by pptn. of Ni vapor on glass, rotational diagrams and a curve are reproduced. The curve shows that at angles up to 10′ the reflection is as high as 97%; it drops steeply at about 20′, and has low maxima again at about 28′ and 38′ for the thin Ni film used (thickness about 220 A. U.). These maxima are explained by reflection on the Ni-glass interface and interference of the 2 reflected rays. From the maxima and minima the thickness of the film was calcd.; also the intensities followed satisfactorily from calcns. B. J. C. VAN DER HOEVEN

The cathode-ray tube in x-ray spectroscopy and quantitative analysis. GORTON R. FONDA AND GEORGE B. COLLINS. *J. Am. Chem. Soc.* 53, 113–25(1931).—A method is described by which the x-ray spectrum of a sample is excited by directing upon it a stream of electrons transmitted by the Al window of a cathode ray tube. The usual photographic method of recording is replaced by a system consisting of an ionization chamber together with amplifying app. in which the new 4-element vacuum tube, FP 54, is employed. The law governing intensity variation, $I = C(V - V_0)^2$ is discussed for the case of the K_α radiation of Fe and Mo. The exponent is found to be correct up to a voltage four-fold that of V_0, the exciting voltage for Mo, and eleven-fold for Fe. Quant. results are presented of the analysis of certain metallic alloys. C. J. H.

Half-life of uranium II. The weight relations of the isotopes uranium I and uranium II in the element uranium. E. WALLING. *Z. physik. Chem.*, Abt. B, 10, 467–75(1930).—The half-life of U-II was detd. by α-ray activity as 340,000 years ± 15% (av. of 3 detns.) For each atom of U-II there exist 13,200 atoms of U-I
W. F. V.

The atomic weight of uranium lead from Swedish kolm. G. P. BAXTER AND A. D. BLISS. *J. Am. Chem. Soc.* 52, 4848–51(1930).—Pb was extd. from the ash of kolm and pure $PbCl_2$ prepd. Nephelometric end points showed this Pb to have an at. wt. of 206.013, agreeing with the fact that no Th was found in the mineral. Ordinary Pb from Coeur d'Alêne Pb-Ag ores yielded an at. wt. of 207.218. L. P. HALL

Obtaining U_3O_8 as a standard of radioactivity. D. K. GORALEVICH. *J. Russ. Phys.-Chem. Soc.* 62, 843–64(1930).—U ore is of a very complex chem. compn., contg.

practically every known element. As U_3O_8 constitutes the adopted standard of radioactivity, its prepn. in the pure state becomes a problem of great importance. This article reports in detail a system worked out by G. for obtaining pure U_3O_8 by starting with uranyl nitrate. Particular emphasis is placed on the elimination of the alkalies, alk. earths, radioactive elements, Mg and, particularly, Th. G. also discusses the products obtained by igniting various salts of uranyl. Thus U_3O_8 obtained from the nitrate is olive-green; from NH_4 salts, black or dark gray; from the chloride, black; from the sulfate, yellowish green; from equimol. mixts. of the chloride and nitrate, coffee-brown. The color of U_3O_8 evidently depends on the size of the particles. The layer of uranyl salt being ignited should not be thicker than 4–5 mm., as otherwise UO_3 is formed along with U_3O_8. D. K.

The atomic weight of uraninite lead from Wilberforce, Ontario, Canada. G. P. BAXTER AND ALLEN D. BLISS. *J. Am. Chem. Soc.* **52**, 4851–3(1930).—To check the age detn. of a specimen of uraninite from Wilberforce (cf. *Trans. Can. Inst. Min. & Met.* 1930, 2; *Am. Mineralogist*, Oct., 1930) the at. wt. of its Pb was detd. as 206.195. Analyses by Wells for Th, U and Pb indicated a value for the Th/U const. of 0.27, instead of 0.36, the usual lead-producing power of Th as compared with U. L. P. HALL

The scattering of hard γ-rays. G. BECK. *Naturwissenschaften* **18**, 896(1930).—Meitner and Hupfeld (*C. A.* **24**, 4698) have shown that γ-rays of 4.7 X. U. are scattered by nuclei. B. demonstrates the theoretical possibility of it for hard γ-radiation and heavy nuclei on the basis of the Klein-Nishina equation. It is suggested that this scattering by nuclei will play a role in cosmic radiation. B. J. C. VAN DER HOEVEN

The constitution of tungsten. F. W. ASTON. *Nature* **126**, 913(1930).—The mass spectrum of W was obtained by using volatile $W(CO)_6$. It proves the presence of the 4 isotopes whose wts. and percentages are: 182, 22.6; 183, 17.2; 184, 30.1; 186, 30.0%. The packing fraction curve indicates a zero value. The resulting chem. at. wt. is 184.96. C. E. P. JEFFREYS

Diffraction phenomena of molecular rays. O. STERN. *Physik. Z.* **31**, 953–5 (1930).—A review. FRANK URBAN

Increased output of electron tubes. NIKOLAUS VERMES *Ann. Physik.* [5], **7**, 257–66(1930); cf. *Ann. Physik.* **4**, 943(1930). J. B. AUSTIN

Secondary electronic emissions from metal foils and animal tissues. W. V. MAYNEORD. *Proc. Roy. Soc.* (London) **A130**, 63–80(1930).—Expts. on small ionization chambers, made artificially sensitive to different x- and γ-radiations by the insertion of foils of different elements, show a max. sensitivity in the region of medium wave lengths when compared to an air chamber. The relative intensity of primary and secondary scattered beams of γ-rays showed differences depending upon the materials of which the chamber was constructed. With ionization chambers contg. animal tissues it is shown that besides a region of max. sensitivity the various tissues diverge by varying amounts from "air equivalence." The significance of these observations is briefly discussed. H. W. LEAHY

The photoelectric effect of aluminum and aluminum-mercury alloys. H. GERDING. *Z. physik. Chem.*, Abt. B, **11**, 1–37(1930).—Photoelec. measurements for Al and Al amalgams show that the photoelec. sensitivity increases greatly by shaving the surfaces in vacuum, the limiting wave length advancing toward the red. The sensitivity decreases with time even in high vacuum, more rapidly in the presence of air, the limiting wave length receding toward the violet; this "exhaustion" is explained by adsorption of air (O_2). Max. sensitivity values, reached by continued shaving of the surfaces, were greater for amalgams contg. 0.38 or 0.26% Hg than for an amalgam contg. 0.06% Hg or for pure Al. L. ONSAGER

The photoelectric effect in metals. HERBERT FRÖHLICH. *Ann. Physik* [5], **7**, 103–28(1930).—On the basis of Sommerfeld's electron theory a theory of the photoelec. effect in thin layers of metal is developed. With the alkali metals this theory yields intensity values and maxima for current and light frequency which agree in general with experimentally obtained values. The difference in behavior of a surface toward fast and slow electrons accounts for the direction of polarization. For fast electrons the atomic structure of the surface is important; for slow electrons the surface may be regarded as smooth. The distribution of energy of the photoelectrons shows a strong maximum near the max. velocity. L. P. HALL

Energy losses of electrons on nitrogen. ERIK RUDBERG. *Proc. Roy. Soc.* (London) A129, 628–51(1930).—The velocity distribution of an initially homogeneous beam of electrons was detd. after passing through a chamber contg. N_2 at a pressure of the order 0.01 mm. The method of velocity analysis was based on a special type of electrostatic deflection, combining considerable resolution with a focusing property for slightly

divergent beams. The distribution curves show 7 maxima in the region corresponding to individual energy losses of 0–30 v. The smallest loss was attributed to collisions with the electrodes. The strongest max., rather sharp, occurred at 12.78 v.; this and one further prominent max. were interpreted as due to excitation of the first singlet level of mol. N_2, known from far ultra-violet spectra. Two further definite maxima are probably related to similar levels; the corresponding spectra have not been classified at present A search for a characteristic energy loss connected with ionization of K electrons from N gave neg. results, although the test was very sensitive. L. O.

The formation of neutral particles of high velocity by charge exchange. H. KALLMANN AND B. ROSEN. *Naturwissenschaften* **18**, 867–8(1930).—It was shown previously (*C. A.* **24**, 4221) that moderate-speed ions acting on a neutral gas charge can give rise to slow ions with high-speed neutral particles. Such exchange occurs frequently. The neutral rays thus produced can be recorded in the following way. When neutral particles at speeds above 100 v. hit a metal plate slow electrons are emitted (Oliphant, *C. A.* **23**, 4135). A wire ring of variable potential was used to measure the electron current thus brought about. When the ring is pos. both ions and neutral particles in the ray are measured, but when the ring is neg. only the ions are measured. The neutral ray produced by a 400-v. argon ion ray had approx. the same intensity as the original ray. B. J. C. VAN DER HORVEN

Discharge of hydrogen canal rays by passage through gases and solid bodies. H. BARTELS. *Ann. Physik* [5], **6**, 957–84(1930).—The discharge of H canal rays by passage through gases at low pressure, and through solid bodies, was investigated by use of a high-vacuum ionization chamber. The app. and prepn. of the materials are described. O was very effective in discharging the rays; curves are given; the effect of the O is const. for canal rays from 30 kv. after the pressure of the O has reached 2×10^{-3} mm. of Hg; further rise in pressure has no effect. N was even more effective than O. H was least effective of the pure gases. The ability of air to discharge the rays was calculable from the data on O and N and was in agreement with expt Curves for all of the cases are given. The course of the curve in which an equil. state exhibits a relationship to the velocity of the rays, was more or less analogous for both the solids and the gases. The discharge coeff. n_-/n_0 for solid bodies was const. for thicknesses greater than 13.3 mμ. WILLIAM E. VAUGHAN

Ionization of noble gases by slow alkali ions. OTTO BEECK. *Ann. Physik* [5], **6**, 1001–24(1930); cf. *C. A.* **24**, 5217.—The ionization of A, Ne and He by Li^+, Na^+ K^+, Rb^+ and Cs^+ was systematically investigated. The app. and method are described in detail. The ionization was general between 100 and 300 v. ion velocity and the curves show a more or less gradual rise up to 500 v. In He the ionization was very slight, not measurable in part. There are some sharp breaks in the curves. Correlation of these points with other data is attempted. B. states that a noble gas atom is most easily ionized by an alkali ion which has the same no. of electrons in the shell as has the gas atom; *e. g.*, Ne by means of Na^+ and A by means of K^+. The data indicate this correlation. Helium is most easily ionized by $Li.^+$ WILLIAM E. VAUGHAN

Measurement of the light yield in the mercury spectrum on excitation by electronic collisions. W. HANLE AND W. SCHAFFERNICHT. *Ann. Physik* [5], **6**, 905–31(1930). cf. *C. A* **24**, 1283.—The radiation produced in a vacuum tube filled with Hg vapor at 10^{-3} mm. by electronic impact with Hg is passed through a filter and detd with a vacuum photoelec. cell (either K or K-Cs type). An electrometer is used for measurement. The cell is calibrated by means of a Hg arc whose emission is detd. by a thermopile, in turn calibrated with a standard lamp. The light yield, *i. e.*, the ratio of quanta emitted to the no. of collisions between electrons and Hg atoms, is detd. for various accelerating potentials in the electron tube. With electrons of 60 v. for each 1000 collisions there are found 2.7 quanta for line 4348, 5.4 q. for 4358, 4.4 q for 5461, 0.85 q. for 5675, 3 4 q. for 5769, 6.9 for 5789 and 5790 together. The method is described in detail. WILLIAM E. VAUGHAN

Magnetic analysis of negative ions in mercury vapor. WALTER M. NIELSEN. *Proc. Nat. Acad. Sci.* **16**, 721–7(1930).—A beam of electrons from a W filament was projected parallel to a magnetic field of approx. 100 gausses, produced by a pair of Helmholtz coils The ions produced were deflected by suitable elec. fields and the ratios of m/e were detd. in terms of the deflection produced by an electromagnet giving fields up to 2000 gausses. The results are displayed as curves giving the ratio of the ion current to the total electron current as a function of m/e. The curve for pos. ions shows peaks corresponding to Hg^+ and Hg^{++} as well as giving evidence of other pos. ions for which m/e has smaller values. The curve for the neg. ions shows a peak at m/e = 200, which is ascribed to Hg^-, as well as several definite peaks lying in the region below m/e 40.

which are ascribed to C, CO and possibly to H_2O. One or two peaks have not been accounted for satisfactorily. W. W. STIFLER

The measurement of the life period of excited helium atoms and a direct method for the determination of the diffusion coefficient of excited atoms. EDGAR EBBINGHAUS. *Ann. Physik* [5], **7**, 257-66(1930).—The life period and diffusion coeff. of metastable He atoms in the 2^3S_1 state have been measured by a method based on the absorption of light. For 1 mm. pressure and room temp. the diffusion coeff. is 400 sq. cm./sec. The diam. of the normal He atom is 2.5×10^{-8} cm. while that of the excited atom is 4.5×10^{-8} cm. This is in accord with theory. J. B. AUSTIN

Paramagnetism independent of the temperature and the existence of electronic isomers in polyatomic ions. SIMON FREED AND CHARLES KASPER. *J. Am. Chem. Soc.* 52, 4671-9(1930).—The variation of susceptibility between room temp. and that of liquid air has been studied for the ions UO_2^{++}, WO_4^{--}, $Cr_2O_7^{--}$. The susceptibility of UO_2^{++} decreases slightly but uniformly with temp. The others showed no variation within exptl. error. A discussion based on Van Vleck's deductions from quantum mechanics is given. J. B. AUSTIN

Kinetics of the thermal transformation of para-hydrogen. A. FARKAS. *Z. physik. Chem.*, Abt. B, **10**, 419-33(1930); cf. *C. A.* **25**, 32.—An amplification of the previous paper. WILLIAM E. VAUGHAN

The crystal structure of para-hydrogen at liquid-helium temperature. W. H. KEESOM, J. DE SMEDT AND H. H. MOOY. *Proc. Acad. Sci. Amsterdam* **33**, 814-9(1930).—Three films made by the Debye-Scherrer method show faint granular lines. The spacings cannot be explained by a cubic lattice but do agree with those calcd. on the basis of a hexagonal closely packed structure $a = 3.75$ A. U., $c/a = 1.633$. This leads to a calcd. density of 0.088. J. B. AUSTIN

Direction of magnetization of single ferromagnetic crystals. F. C. POWELL. *Proc. Roy. Soc.* (London) **A130**, 167-81(1930).—When a magnetic field is applied to a crystal the direction of magnetization does not, in general, coincide with that of the field. Gans recently attempted to account for this on the assumption that the elementary magnets are electron orbits, and had at least partial success with Fe and pyrrhotite. There are 2 objections to this theory, *viz.* (1) that it does not hold quantitatively for non-magnetic crystals, such as Co, and (2) that the elementary magnets should be ascribed to electron spins rather than to electron orbits. P. then proposes a theory based on the magnetic interaction between each electron and the atom to which it belongs. This interaction is represented by a field G, fixed in the crystal, called the "crystalline field." It may be in a no. of possible directions which bear simple relations to the crystal structure. The math. part of the theory as worked out is based on certain equations developed by Dirac and Heisenberg. When applied to Kaya's data for Fe and Ni, the results to be good agreement between calcd. and exptl. results. For Ni, G = 5×10^5 gausses and for Fe it is of the order of 10^6 gausses. It is then shown that the theory may be applied to a non-cubic crystal with satisfactory results and for Co it is shown that G is not less than 4.5×10^6 gausses. W. W. STIFLER

Paramagnetic rotation in the uniaxial crystals of the rare earths. H. A. KRAMERS. *Compt. rend.* **191**, 784-6(1930); cf. *C. A.* **24**, 2046.—The magneto-optic effects in uniaxial crystals of the rare earths indicate that the metallic ions are in an intense elec. field, symm. with respect to the optical axis, which is attributed to the neighboring ions. The particular forms which the equation for this field assumes for xenotine and tysonite are discussed. W. W. STIFLER

The paramagnetic rotatory power of crystals of xenotine at very low temperatures and the paramagnetic saturation. JEAN BECQUEREL AND W. J. DE HAAS. *Compt. rend.* 191, 482-4(1930); cf. *C. A.* **24**, 2046.—Expts were made on crystals placed with the optical axis parallel to the light and to the magnetic field for wave lengths 5616 and [illegible] A. U. At the temp. of liquid He, and a field of approx. 20,000 gausses, practically complete paramagnetic satn. was obtained. When the rotation is plotted as a function of H/T, the curves for $T = 4.22$°K. and $T = 1.38$°K. have the same asymptote, although they do not seem to follow exactly the same law. They indicate a magnetic moment between 6.5 and 7 Bohr magnetons. The curve for $T = 14.34$°K. follows the hyperbolic tangent law and indicates a magnetic moment in the vicinity of 7 magnetons. W. W. STIFLER

The nuclear moment of sodium. S. FRISCH AND A. FERCHMIN. *Naturwissenschaften* 18, 866(1930).—From the study of the hyperfine structure of Na II with a quartz Lummer plate in the near ultra-violet (cf. *C. A.* **22**, 3584) the majority of these lines were found to be narrow doublets. For the lines at 3711, 3631 and 3533 A. U. the photometer curves are given. The 3711 A. U. line is single ($3P_2 - 3S_1$); the other 2

have $\Delta\lambda$ 0.025 and 0.020 A. U. resp. ($3P_1 - 3S_1$ and $3P_2 - 3S_1$). **Conclusion:** The nuclear moment of Na is $i = 1/2$. With Fermi's calcns. (*C. A.* **24**, 1791) a value of μ_o $\mu/890$ is found (μ is the Bohr magneton, μ_o the magnetic moment of the nucleus).
B. J. C. VAN DER HOEVEN

Arc spectrographic estimation of chromium in ruby. JACOB PAPISH AND WM. J. O'LEARY. *Ind. Eng. Chem., Anal. Ed.* **3**, 11-3(1931).—The effect of concn. of Cr in detg. the persistence of its spectral lines in the region between 5785.8 and 3120.4 A. U. has been studied both with Cr introduced into the arc as chromic acid and in the form of synthetic rubies consisting of a mixt. of fused chromic oxide and alumina. The sensitive lines are found to persist with smaller concns. in the oxide mixts., a concn. of 0.001% being sufficient to excite the lines at 4289.7, 4274.8 and 4254.3 A. U. The results made possible an estn. of the Cr content of 8 samples of natural ruby, of which 2 were available in sufficient amts. to check the result by direct analysis. C. J. H.

The red coronal line in oxygen. JOHN J. HOPFIELD. *Nature* **126**, 846(1930).—A strong line λ6374.29 A. U. on spectrum plates of O_2 seems to be identical with the red coronal line λ6374.2 A. U.
ARTHUR FLEISCHER

. *J. Soc. Chem. Ind*

spectra of cyanogen

cyanogen-O flame. The absorption spectrum obtained was: 3.71, 3.85, 4.55, 15.5 and 16.1μ. The explosion spectrum band of 2.8μ probably confirms the assumption that the spectrum will be like that from CO-O mixt., *i. e.*, 2.8 and 4.4μ
ALLEN S. SMITH

Spectrum of hydrogen bromide. W. WEIZEL, H. W. WOLFF AND H. E. BINKELI *Z. physik. Chem.*, Abt. B, **10**, 459-66(1930).—A discharge in HBr gives a continuous spectrum that increases in intensity from the green toward shorter wave lengths. In the near ultra-violet several maxima exist. The continuous spectrum is interpreted as the dissocn. spectrum of HBr or HBr^+.
WILLIAM E. VAUGHAN

Determination of the abundance ratios of isotopes from band spectra. A. ELLIOTT *Nature* **126**, 845-6(1930); cf. *C. A.* **24**, 5227.—An account of the detn. of the correction necessary to obtain abundance ratios from intensity data is presented with more complete data.
ARTHUR FLEISCHER

The relation between molecular structures and absorption spectra. E. K. PLYLER *J. Elisha Mitchell Sci. Soc.* **46**, 22(1930).—The results of infra-red absorption measurements indicate that all materials contg. C and H have absorption bands in the region of 3 and 6μ.
A. L. MEHRING

The constitution of prussic acid. A. DADIEU. *Naturwissenschaften* **18**, 895(1930).—The Raman spectrum of pure dehydrated HCN was again detd.; besides the known frequency of 2094 cm.$^{-1}$ (intensity 12) 2 weak bands at 2062 (1/2) and 3220 (2) cm.$^{-1}$ were found. The 2062 line is not due to dissocn. It is assumed that 3220 is a vibration of H with respect to CN with increased C-H frequency due to triple bond. The other 2 lines are due to the 2 isomeric forms of HCN: 2094 to normal HCN, 2062 to the isonitrile form. For the latter a triple bond is thereby indicated: $H—\overset{+}{N}\equiv\overset{-}{C}$ in agreement with results of Lindemann (*C. A.* **24**, 5018).
B. J. C. VAN DER HOEVEN

New bands in the secondary spectrum of hydrogen. III. D. B. DEODHAR *Phil. Mag.* **10**, 1082-95(1930); cf. *C. A.* **24**, 2952.—The data of Part II are discussed and interpreted. Data and calcns. are given in tabular form.
W. E. V

The emission spectra of some simple benzene derivatives. JAMES B. AUSTIN AND IAN A. BLACK. *J. Am. Chem. Soc* **52**, 4755-62(1930).—The emission spectra of *toluene ethylbenzene* and *o-, m and p-xylene* have been photographed with the Tesla discharge for excitation. They contain a no. of bands in the region 2600 to 2900 A. U. which are generally accompanied by a continuous background.
J. B. AUSTIN

Ultra-red spectrum filters. H. G. HIRSEKORN. *Ann. Physik* [5], **6**, 985-1000 (1930).—The transmissivity of thin layers of NaCl, KCl, NH_4Cl and TlCl (prepd. by evapn. was investigated spectrometrically in the region from 40 to 140μ. All of the substances show that they act as selective filters in this region. The width of the absorption region decreases in the order of the following: NaCl, NH_4Cl, KCl and TlCl. All of the substances show a gradually subsiding transmission increase on the long wave-length side. With NaCl, NH_4Cl and TlCl there appear 2 and with KCl possibly 3 symmetrically arranged transmission minima. The problem is complicated by interrelationships of absorption, reflection and transmission and scattering properties of the thin layers.
WILLIAM E. VAUGHAN

Chemical constitution and Raman effect, ethylene hydrocarbons. R. LESPIEAU AND M. BOURGUEL. *Bull soc. chim.* [4], **47**, 1365-76(1930).—See *C. A.* **24**, 4460. G. G.

Chemical constitution and Raman effect; the acetylene linkage. M. Bourguel and P. Daure. *Bull. soc. chim.* [4], **47**, 1349–65(1930).—See *C. A.* **24**, 4222. E. C. K.

The Raman effect at the critical point. G. Placzek. *Proc. Acad. Sci. Amsterdam* 33, 832–40(1930).—Intensity measurements have been made on the Raman spectrum at the crit. mixing temp. of a mixt. of CH_3OH and C_6H_{14}. They show that the intensity of the Raman lines of each component remains unchanged as the crit. temp. is approached while that of the continuous spectrum increases. This continuous effect is attributed to vibrations of mol. complexes. The bearing of these observations on the theory of liquids is discussed. J. B. Austin

Raman spectra of pinene. G. B. Bonino and P. Cella. *Nature* **126**, 915(1930).—In liquid *d*- and *l*-pinene, a series of very weak lines was found, whose distance from the Raman frequency, 1454 cm.$^{-1}$, excited by the Hg line $\lambda = 404.6$ A. U. could be represented by $\Delta\nu = 6.15\ (4\ m + 4)$, $m = 2, 4, 6$, etc., which corresponds to the series of Raman frequencies of rotation relative to the rotator with fixed axis. By supposing the rotator composed by 2 atoms of H of 1 CH_2 group rotating around the C atom (the Raman frequency, $\nu = 1454$, being attributed to the transverse oscillation of 2H atoms in the CH_2), the value $1.16\ 10^{-8}$ cm. was calcd. for the distance between the atoms of H and C in the CH_2 group. C. E. P. Jeffreys

Studies in Raman effect. VIII. Calculation of simple molecular models. Michael Radaković. *Monatsh.* **56**, 447–60(1930).—Mathematical. **IX. Raman spectra of organic substances.** A. Dadieu and K. W. F. Kohlrausch. *Ibid* 461–76.—Raman spectra of *propionitrile, benzonitrile, methylene bromide, methylene iodide* and *dimethylaniline* are given and discussed in relation to Raman spectra of other compds. (cf. *C. A.* 24, 5026). L. Onsager

Raman lines of simple polyatomic molecules. G. B. B. M. Sutherland. *Nature* 126, 906–7(1930).—The Raman spectrum of N_2H_4 showed 3 lines of roughly the same intensity at 3196, 3270 and 3344 cm.$^{-1}$, along with a very doubtful line at 1720 cm.$^{-1}$. These lines correspond to N-H vibrations, and the sym. N-N vibration was extremely weak if present at all. $N_2H_4.H_2O$ gave the same 3 lines with less intensity. C. E. P. J.

The Geiger-Müller tube as a quantitative ion counter. J. A. Van den Akker. *Rev. Sci. Instruments* **1**, 672–83(1930).—The new Geiger-Müller ion-counter tube is accurate only when the rate of counting is as low as 300/min. Various spurious discharges occur which seem to be due to temporary disruptions of ion layers in the tube, causing abnormally high values of the field gradient. Gregg M. Evans

The liberation of electrons from a metal surface by positive ions. II. F. M. Penning. *Proc. Acad. Sci. Amsterdam* **33**, 841–57(1930); cf. *C. A.* **22**, 1097.—In continuation of previous assumptions it is shown that neutral particles do not liberate any appreciable no. of electrons. The condition of the metal surface has also been investigated. The no. of electrons liberated from W per pos. ion depends on the extent of outgassing of the W surface. The no. of electrons per ion of 500 v. energy on properly degassed W is 0.20 ± 0.02. A no. of complicated tubes are described. J. B. A.

The emission of electrons under the influence of chemical action at lower gas pressures. O. W. Richardson and L. G. Grimmett. *Proc. Roy. Soc.* (London) **A130**, 217–38(1930); cf. *C. A.* **16**, 1703; **18**, 1945–6, 2466.—A method is described by which the partial pressures of $COCl_2$ can be controlled and their changes measured down to 10^{-5} mm. Hg. The electron emission from NaK in this gas was directly measured to pressures of 10^{-3}, pressures of 5×10^{-7} being extrapolated. In contrast to the results obtained above 10^{-4}, the emission is now found to be a function of the pressure as R. originally supposed. Evidence is presented to show that the experimentally detd. velocity distribution function among the electrons approaches a limit as the pressure is reduced. H. W. Leahy

The photoelectric properties of ammonia catalysts. A. Keith Brewer. *J. Am. Chem. Soc.* **53**, 74–83(1931).—Unpromoted Fe catalysts as well as those promoted with Al_2O_3 have the photoelec. characteristics of pure Fe; those promoted with K_2O or with $K_2Al_2O_4$ have long-wave-length limits that lie between those of metallic K and those of pure Fe, the limit for the K_2O-promoted catalyst being much farther toward the red than that for the $K_2Al_2O_4$-promoted catalyst. It is suggested that the known poisoning effect of K_2O present as a single promoter in NH_3 catalysts may be due to the metallic K formed by dissocn. of the K_2O. P. H. Emmett

Energy losses of electrons in carbon monoxide and carbon dioxide. Erik Rudberg. *Proc. Roy. Soc.* (London) **A130**, 182–96(1930); cf. *C. A.* **24**, 3431, 4696, 4986.—Previous measurements of the energy losses suffered by electrons in N at low pressures by R. have been extended to CO and CO_2. The energy distribution of the electrons

after passing through the gas shows several well-marked maxima which were measured for different voltages and pressures. The maxima are characteristic for the mols. used. With CO the various maxima are correlated with the transitions from the normal state to the excited states known from analysis of the band spectra belonging to the mol. or to singly ionized CO. In these cases where a max. has been attributed to a single electron level, a study of the potential curves for the mol. shows the position of the max. to be in accordance with the Franck-Condon theory. H. W. L.

Fracture of discharge tubes. R. H. SLOANE. *Phil. Mag.* **10**, 1099–102(1930).—Some rather detailed observations are made on the breakdown of discharge tubes.
WILLIAM E. VAUGHAN

Photometric measurements of the concentration and dispersion in colloidal solutions. I. Measurements on decrease in light intensity. TORSTEN TEORELL. *Kolloid-Z.* **53**, 322–38(1930).—The decrease in light intensity of light obtained with monochromatic filters on passing through colloidal solns. of mastic, Fe hydroxide and gelatin was measured with a Pulfrich photometer. The factors studied are the layer thickness, concn., wave length of the light employed, particle size, particle form, index of refraction and hydration. The Lambert-Beer law was obeyed over a wide range for layer thickness. The hydrophobe sols obey Beer's law for concn. up to high values. For colorless or white sols filters for 470 or 570 mμ are suitable for dil solns., and 610 or 720 for more concd. solns. The weakening of light increases rapidly with increase in particle size, reaching a max. and then decreasing. The max. is displaced to larger particles with increasing wave length, but the value of the max. decreases. Solvated colloids do not follow the Lambert-Beer law and empirical relations must be used.
A. FLEISCHER

Spectrophotometric investigations on the action of light on nuclear silver sols. A. GALECKI AND R. SPYCHALSKI. *Kolloid-Z.* **53**, 338–52(1930); cf. *C. A.* **22**, 4027, 25, 459.—From measurements of the ultra-violet light sensitivity, viscosity change at 25° by radiation, and change in cond., the following mechanism is proposed for the action of light on Ag sols. The ultra-violet light causes the formation of H_2O_2, which dissolves the colloidal Ag and decolorizes the soln. by forming Ag ion, which may subsequently be reduced by the action of the ultra-violet light. Spectrophotometric measurements at 510 mμ were carried out to det. the reaction mechanism. Under the influence of light, it is a reaction of the first order. At 29° the velocity const. varies from 0.0875 to 0.2104 and at 10° from 0.0528 to 0.1345, the individual value depending on the particular soln. The mean value for the temp. coeff. is 1.3. A. F.

The behavior of cathode rays on cellulose preparations. C. TROGUS, H. HAUBER SCHADT AND K. HESS. *Naturwissenschaften* **18**, 846–7(1930).—Thomson has reported Debye-Scherrer interference obtained on irradiation of cellulose with cathode rays (*C. A.* **22**, 1723) (also Kirchner, *C. A.* **24**, 5604). The authors found that ash-free cigaret paper does not give a diffraction effect when perpendicularly incident rays from an incandescent cathode are used. If the same paper is provided with a pinhole and irradiated near it, it gives a no. of interference spots attributed to diffraction at the edges of the hole. Reproductions are given of these photograms obtained with 5 and 10 kv. potential, 2 to 10 sec. exposure. The character of the diagram is like that of mica monocrystals (cf. Kikuchi, *C. A.* **22**, 4052). The sharpness of the spots decreases with increasing potential. Diffraction effects were observed by tangential irradiation of fibers of acetylcellulose II or of natural silk.
B. J. C. VAN DER HOEVEN

Catalytic influence of light on efflorescence of a salt. ERNST BEUTEL AND ARTUR KUTZELNIGG. *Monatsh* **56**, 184–90(1930).—Light causes a decided increase in the velocity of efflorescence in most hydrates. Depending upon the case with which the resp. salts give up their water, radiated ones give off 1.5–5.0 times the amt. of those held in the dark for the same time at the same temp. Detailed results of 15 salts are given.
GREGG M. EVANS

A study of some of the chemical characteristics and the absorption spectrum of cystine. MARY L. FOSTER, GLADYS A. ANSLOW AND DOROTEA BARNÉS. *J. Biol. Chem.* **89**, 665–73(1930).—The ultra-violet absorption curves of *l*-cystine in HCl and water show only continuous absorption and are similar to those of alanine. Since tyrosine, uric acid, etc., exhibit selective absorption it is concluded that cystine cannot possess the ring structure suggested by Ward (*C. A.* **18**, 1117). From the absorption coeff. the % dissocn. produced by light is calcd. to be 2×10^{-8} at 4000 A. U., the energy of dissocn. being 70,800 cal. per g.-mol. The p_H of optimum pptn. of cystine varies with the concn. of the soln.
K. V. THIMANN

Comparison of molecular ionizing potentials in an alternating electric wind. W. M. THORNTON. *Phil. Mag.* **10**, 1052–63(1930).—Ionizing potentials were detd. in an app.

in which the gas under investigation was enclosed in a glass chamber with the hot wire. A p. d. was applied to the hot wire and another electrode outside the glass chamber. Voltages as high as 60 kv. were used. The galvanometer deflections of a bridge of which the hot wire is one arm are detd. for varying voltages and several of these plots are given. From the curves and the measured slopes, the mol. ionizing potentials of the various materials studied can be calcd. The gases investigated are A, Ne, He, H_2, O_2, N_2, air, CH_4, C_2H_6, C_3H_8, C_4H_{10}, C_5H_{12}, C_2H_2, C_2H_4, $CHCl_3$, Et_2O, CO_2, CO, NO, NH_3, CS_2 and H_2O. The data are summarized. WILLIAM E. VAUGHAN

Polarization phenomena in the stepwise activation of the fluorescence of mercury. L. F. RICHTER. *Ann. Physik* [5], **7**, 293–328(1930).—A color effect produced by polarized radiation in a mixt. of N and Hg vapor has been investigated spectroscopically. The polarization and Zeeman patterns of the lines have also been observed. The color is laid to stepwise activation. Quant. measurements of the degree of polarization of the excited lines show only a qual. agreement with theory. The deviations from theoretical values are of the same order of magnitude as those in Hg resonance radiation and are explained in the same way. Ultra-violet lines show the same behavior as visible ones. Measurements of the angle of rotation and of depolarization give approx. the same results for the half life period of the excited atoms. The variation of life period with pressure of the added N shows that it is impossible to extrapolate to the life period *in vacuo*. J. B. AUSTIN

A new method of producing and controlling the emission of positive ions. F. G. CORRELL, C. H. KUNSMAN AND R. A. NELSON. *Rev. Sci. Instruments* **1**, 654–61(1930).—By shrinking a Na-free capillary glass tube upon a Pt strip and then electrolyzing K from fused KNO_3 into the space between the strip and the glass, a reservoir of K is produced. A Pt layer is then sputtered upon the outer surface of this anode. Electrically heating the filament strip, electrolyzing K from the reservoir to the outer coating, and applying a plate potential between anode and a cylindrical cathode provides a source of pos. ions which is const. for long periods of time. Since the cathode surface is at low temp., surface action is reduced to a min. The ion current is subject to easy control by means of the electrolyzing potential. GREGG M. EVANS

Spectroscopic study of the decomposition and synthesis of organic compounds by electrical discharges. I. The electrodeless discharge. WM. D. HARKINS AND DAVID T. WILLIS. *J. Am. Chem. Soc.* **52**, 5165–75(1930); cf. *C. A.* **24**, 3440.—The electrodeless discharge in the vapors of benzene, phenol, aniline acetylene, naphthalene and pyridine has been exaind. spectroscopically for the purpose of detg. the decompn. products of the discharge. The following were found in all cases: CH, C_2, C, H and C^+. Phenol showed in addn. OH, H_2O and CO, and the aniline discharge indicated CN, NH^+, and N_2^+. All these intermediate decompn. products are extremely active and coalesce very rapidly to form brown or black solids which are insol. in water and org. liquids and probably have high mol wts. Heptane, unlike the unsatd. hydrocarbons, gives very little solid in the type of app. employed. C. J. HUMPHREYS

Thermal and photochemical decomposition of ozone. HANS J. SCHUMACHER AND GERHARD SPRENGER. *Z. physik. Chem.*, Abt. B, **11**, 38–44(1930).—The authors maintain their standpoint (*C. A.* **24**, 2946, 4224) on the mechanism of ozone decompn. against that of Riesenfeld and Wassmuth (*C. A.* **24**, 5592). L. ONSAGER

The photochemical reaction between ethylene iodide and iodine in carbon tetrachloride solution. HANS J. SCHUMACHER AND EDWIN O. WIIG. *Z. physik. Chem.*, Abt. B, **11**, 45–55(1930).—The photochem. reaction between $C_2H_4I_2$ and I_2 in CCl_4 solution can be described by the equation: $d[C_2H_4I_2]/dt = k\sqrt{J_{abs}}[C_2H_4I_2]$, where J_{abs} = light absorbed. The temp. coeff. at 100° is 1.57 per 10°. The mechanism is a chain of simple type, involving I atoms; the only difference from the dark reaction (cf. *C. A.* **24**, 5255) is the displacement of the I_2 dissocn. equil. by light. L. ONSAGER

Decomposition of thiocyanates in ultra-violet light. K. JABLCZYŃSKI AND H. JABLCZYŃSKA. *Rozniki Chem.* **10**, 579–99 (599–600 German)(1930).—The decompn. of NH, K and Na thiocyanates under the influence of ultra-violet light of a quartz lamp of Heraeus type was investigated spectrophotometrically. The decompn. was accompanied by a sepn of S. As this reaction takes place endothermally the opposite reaction, that is the formation of the thiocyanate from S, must proceed spontaneously in distant places of the soln. Both simultaneous processes must lead to an equil. which was observed experimentally. It was found that the decompn. reactions of thiocyanates are autocatalytic and correspond very well with the equation $K = [1/(1+d)t] \log[(x+d)/d(1-x)]$, where t is time, x degree of partial turbidity and d is a const. When to a fresh soln. of the thiocyanate a little of the turbid soln. of the preceding expt. is

added the reaction velocity is greatly accelerated. With the dilution of the thiocyanate the equil. point is displaced and a max. of the reaction velocity appears on the concn. line. The temp. has a big influence on the velocity. It is true the main reaction (decompn.) being photochemical should be independent of the temp. yet the opposite reaction depends upon the temp. to a large extent. The addn. of an acid increases the velocity supposedly because the thiocyanic acid set free is more easily decompd. than its salts. Addn. of KCl, Zn and Ni sulfate to KCNS soln. accelerates the decompn. which is dependent on the cation. The decompn. of NH_4, K and Na thiocyanates takes place only under the influence of rays of length of 3000 and 1850 A. U. J. K.

The lattice energies of the silver halides and their photochemical decomposition. II. S. E. SHEPPARD AND W. VANSELOW. *J. Phys. Chem.* **34**, 2719–48(1930); cf. *C. A* **23**, 1819.—The importance of lattice energy for light absorption and photodecompn. of crystals is affirmed. Sommerfeld's "electron gas" theory and Pauling's "electron affinity of the crystal" conception are analyzed and certain objections to the latter are raised. Pauling's theory is replaced by the virtual field (lattice potential) of the metal released by photoionization, since better agreement is obtained between the observed and calcd. wave-length limits of absorption. It is suggested that the deformation of anions by cations with large external electron sheaths tends to shorten the wave-length limit of absorption rather than to extend it. Adsorption effects supporting the opposite view are ascribed to lattice loosening. H. W. LEAHY

Luminescence from solidified gases at the temperature of liquid helium. L. VEGARD AND W. H. KEESOM. *Comm. Phys. Lab. Univ. Leiden* No. **205b**, 49–114(1930); cf *C. A.* **24**, 2670.—Expts. were made with cathode rays. No polarization effects were found. Again N_2 and N_4 appear in the afterglow, with N_3 very faint and of short duration, indicating that N_2 and N_4 are characteristic of the solid state. Their wave lengths agree satisfactorily with the red and green aurora lines. Mixed with Ne these lines are displaced toward the red. Three diffuse lines identified as new components of the η-series (ϵ-system) were found. Ne with 1.6% N shows in the green and red only the 4 auroral lines. These shift and approach the auroral frequencies with diminishing concn. of N. The N_2 band may consist, according to conditions, of a narrow band with an av. wave length of 5206 or 5238 A. U. explaining former results (cf. *C. A.* 21, 3311). The results of both this and the previous article are tabulated and summarized both with respect to conditions under which the lines occur and with respect to the various series. Extended theoretical discussion is deferred to a future paper GREGG M. EVANS

Luminescence from solidified gases at the temperature of liquid hydrogen. II. Luminescence produced by canal rays. L. VEGARD. *Comm. Phys. Lab. Univ. Leiden* **205a**, 3–45(1930); cf. *C. A.* **24**, 1288.—A continuation of earlier investigations in which cathode rays were used. Measurements of lines are given tabularly and spectrographs reproduced that were taken (*a*) with a glass spectrograph of the solid systems N, A and A + 1.2% N, and (*b*) with a large quartz spectrograph of the solid systems A, A + 1% N, A + 2.2% N and A + 30% N. These show in each case both the spectrum of the direct light and the afterglow. In this work certain lines of gaseous N_2 such as the N_1 line appear in the direct spectrum. The *A* band which remains in the afterglow seems to be characteristic of solid N. A new series in N, the *E*-series was noted. This is possibly connected with the third pos. group of N. In A, and A-N mixts. a χ-series, some lines of which had already been observed, was classified and 2 new lines were noted. The α- and η-series seem to dominate in the afterglow. A κ-series similar to the ϵ-series may have the latter's lower level but a different upper level. The *G*-*G'* system is now seen to correspond to the third pos. group of N bands, and probably arises from gaseous N_2 mols. temporarily liberated from the solid system by the intense energy of stoppage of the canal rays. The α-series is believed to be characteristic of the mol. elements of the crystal lattice of N, and is referred to an oscillatory system corresponding to the bottom level of the *G*-series. GREGG M. EVANS

Changes in the absorption spectrum of a dye solution due to the introduction of a colloid. A. BOUTARIC AND M. DOLADILHE. *Compt. rend.* **191**, 1008–11(1930).—Introduction into a colloidal dye soln. of a lyophobic sol of opposite charge decreases the opacity of the former. The ordinates of the absorption curve all decrease by the same fraction. This also occurs when lyophilic colloids are added. In this case, the magnitude of the shift is a function of the p_H changes. If the introduced lyophobic sol has the same charge, no change is observed. Whenever these effects are not observed, this is a true dye soln. FRANK URBAN

Electronic arrangement in the principal organic bindings. MANFRED DUNKEL. *Z. physik. Chem.*, Abt. B, **10**, 434–58(1930).—Theoretical. Recent work on the struc-

ture of simple substances is utilized in an attempt to make statements relative to the structure of more complex org. substances. The polarizability of atoms and their spatial arrangement in mols. is related to electronic structure. The electrons shared in certain bonds are classified and various groups of materials are subdivided according to this idea. WILLIAM E. VAUGHAN

Radioactive preparations. DEUTSCHE GASGLÜHLICHT-AUER-GES M. B. H. Fr. 691,215, Mar. 5, 1930 Radioactive prepns. pptd. on supporting materials are lixiviated with solns. which lower the soly. of the pptd. salt or liquids in which the salt is more difficultly sol. than in water, *e. g.*, solns. of $(NH_4)_2CO_3$. Fr. 691,217 describes the manuf. of concd emanation prepns. by using strongly active charcoals or SiO_2-gel to absorb the emanation.

Phosphorescent letters, signs, etc. DEUTSCHE GASGLÜHLICHT-AUER-G. M. B. H. Fr. 510,565, Sept. 14, 1928. The color or pigment is mixed to a paste with a small quantity of highly viscous binding material and applied to indifferent material. Thus, radioactive ZnS is mixed to a paste with highly viscous nitrocellulose soln. and applied to celluloid.

Luminescent surfaces. LUMINOSE S. A. Fr. 689,925, April 25, 1929. Plates, films or other surfaces are covered with a luminescent layer on which is applied a layer sensitive to light contg. an agglomerant not attacked by the ordinary reagents used for photographic treatments. An image is obtained on the sensitive layer and developed, and the proof has the peculiarity of being visible at night while having the appearance of an ordinary photograph during the day. Fr. 689,939, Apr. 26, 1929, describes the prepn. of luminescent surfaces on paper, etc., resistant to atm. agents and capable of receiving typographic, lithographic or heliographic printings, by depositing on the paper a layer of luminescent salts agglomerated by a mixt. of soap, gelatin and alum. The surface is allowed to dry and is calandered.

COLIN G. FINK

Economy of electrothermal zinc recovery. RICHARD ROSENDAHL. *Metall u. Erz* 27, 616-7(1930).—Comment is made on a paper under the same title by Walter (*C. A.* 24, 5626). H. STOERTZ

The electrical conductivity and tensile properties of light magnesium-aluminum alloys as affected by atmospheric exposure. ERNEST WILSON. *J. Inst. Elec. Eng.* **69,** 89-94(1930).—The 0.5% Mg alloy of Al (Aldrey) is being used in Continental Europe for overhead elec. conductors without steel cores. The results of exposure tests of this type of metal to London atms. are indicated. The conductors were in the form of wires, and variations in elec. and mech. properties have been studied with special reference to type of corrosion and mech. stress during exposure. Increased stress has been beneficial as far as variations in tensile properties are concerned but has little effect upon elec. cond. Expts. are described that attempt to explain the reason for the beneficial results obtained. Phys. tests and chem. analyses of the Mg alloys used are tabulated, and variation of elec. cond. as a function of the time of exposure is shown by a curve.

Reference is made to published work on the atm. exposure of light Ni alloys, duralumin and high-purity Al, and comparisons are made with the present expts. An attempt is being made to det. the effect the nature of the corroded surface of Aldrey will have upon *corona* production, in comparison with the corroded surfaces of other light Al alloys. W. H. BOYNTON

Debismuthizing lead with calcium. RALPH F. COHN. *Trans. Electrochem. Soc.* 59 (preprint) 6 pp.(1931).—Desilverized Pb contg. one-tenth to one-third of a % of Bi is not suitable for white-lead manuf. The Betts' electrolytic Pb process for the elimination of the Bi is applicable, but the new process herewith presented is more economical. Metallic Ca is introduced into molten Pb. A Ca-Bi dross is formed. The Bi in the Pb is reduced to less than 0.05%, and the last traces of As, Sb, Ag and Cu are scavenged. The slight excess of Ca remaining in the Pb is removed with Cl. The dross is submitted to the Betts' process. The theory and economics of the new process are discussed at length. C. G. F.

Effect of various metallic sulfates upon the throwing power of a chromium plating bath. LAWRENCE E. STOUT AND JONAS CAROL. *Ind. Eng. Chem.* **22**, 1324–5(1930).—The addn. of Ni, Co, Zn or Cd sulfates to a chromic acid plating bath in the ratios of CrO_3-SO_4 of 200:1 or 150:1 increases the throwing power of the bath. When used in these proportions, $CdSO_4$ gives the greatest throwing power, Ni and Co sulfates give deposits much more resistant to the solvent action of HCl, and these metals do not deposit at the cathode with the Cr. C. L. READ

The time factor in anodic passivation of metals (gold, iron). WM. J. SHUTT AND VINCENT J. STIRRUP. *Trans. Faraday Soc.* **26**, 635–42(1930); *J. Electroplaters & Depositors Tech. Soc.* **6**, 41–8(1931).—Passivation of Au in 2 *N* HCl was studied with a rotating commutator recording time, current and potential on an oscillograph. The time (t) required for the Au to become passive depended on the current density (c) and the temp. At 9.5°, $(c - 0.58)\ t = 0.11$. The time of recovery depended only on the temp. Essentially the same results were found with Swedish Fe in H_2SO_4. Interpreted in the light of recent theory (*C. A.* **19**, 1538), these exptl facts indicate that the OH-ion concn. increases until O should be liberated, but because of the high overvoltage of O, the potential rises still higher until Cl is evolved with HCl or O with H_2SO_4. L. P. HALL

Electrode potentials in air-free electrolyte. A. L. MCAULAY, G. L. WHITE AND E. C. R. SPOONER. *Nature* **126**, 914–5(1930).—Expts on Fe, Cd and Zn and some rough measurements on other metal electrodes show that when there is no sensible concn. of the ions of a metal electrode in a soln., and when the electrode is not covered by an oxide film, its potential is detd by p_H if its H_2 overvoltage is pos. to the deposition potential which it would have in a soln. of the order of 0.001 *N* of its own ions. When this is not the case, the potential is controlled by anion concn. probably acting through a film of electrolyte in contact with the metal with a concn. of electrode-metal ions of the order of 0.0001 *N*. Reproducible potentials for high-overvoltage metals were found. The reason for this is under investigation. C. E. P. JEFFREYS

Experimental investigations on the lead accumulator. E. DENINA. *Atti soc. ital. progresso sci.* **18**, 135–40(1929); cf. *C. A.* **22**, 2516.—From the expts. and the thermodynamical calcns it is shown that the pos. plates of the normal Pb accumulator are formed by the couple $PbO_2|PbSO_4$ with exclusion of peroxides and other compds. G. A. BRAVO

Electrolytic fixation of compressed nitrogen at ordinary temperatures. FR. FICHTER, PIERRE GIRARD AND HANS ERLENMEYER. *Helv. Chim. Acta* **13**, 1298–306 (1930); cf. *C. A.* **16**, 2440.—E. found that Li catalyzed the cathodic reduction of N. Accordingly, LiCl soln. in abs. EtOH was electrolyzed between a water-cooled Pt cathode and graphite anode, the cell being placed into a hermetically sealed chamber filled with N at pressures up to 1000 atm. At 1 atm. N no appreciable amt. of NH_3 was formed, although Li metal was deposited. A soln. of $LiC_2H_5O_2$ in EtOH produced no Li upon electrolysis. As the N pressure was increased, the amt. of NH_3 formed increased. At 1000 atm. 22.3 mg. NH_3 per amp. hr. was produced. The catalytic effect of Li is due to the intermediate formation of Li_3N, which then reacts with the EtOH: $Li_3N + 3C_2H_5OH = 3LiOC_2H_5 + NH_3$. Li metal is sol. in abs. EtOH. Expts. with LiBr in EtOH were not as good as those with LiCl. Upon electrolyzing LiCl in butyl alc. (b. 116°) the output of NH_3 at 1000 atm. N ranged from 20.6 to 23.5 mg./amp. hr. MARY E. LEAR

Glow discharge at the active electrode of an electrolytic rectifier. JOHN S. FORREST. *Phil. Mag.* **10**, 1003–14(1930).—Three types of cells were used: Al in NH_4 phosphate; Ta in dil. H_2SO_4 with $FeSO_4$ added; W in dil. H_2SO_4. Pb was used as the inactive

lectrode in all cases. A dull glow is observed at the active electrode surface with the assage of current at some definite potential; this was 60 v. for the Al cell. As the oltage increases the glow increases and sparking occurs (at 150 v. for the Al cell). The sparks are replaced by an arc of a reddish color and breakdown takes place; this ecurs at 200 v. for the Al cell, 115 for the W cell and at approx. 90 for the Ta cell. ther observations of a qual. nature are given. Measurement shows that the layer gas on the active Al electrode is approx. 10^{-6} cm. thick. The spectrum of the glow hows it to be brightest at about 5550 A. U. This is attributed to O under weak ex- itation. Magnetic fields of 4000 gausses had no effect upon the current through the ells and the appearance of the glow. The pressure of the gas at the surface is thought to be many atms. The intensity of the glow is primarily a function of the current; the curve is slightly concave upward. This is attributed to the increase in the thick- ness of the gas layer with increase in the current and voltage. Possibly a satn. value may be attained, although this was not realized. The cathode glow becomes visible at approx. the same voltage as the anode glow. The cathode glow must be viewed by means of a stroboscope. The general characteristics of the cathode glow are similar to those of the anode. Twenty-five cycle current was used in all of the expts. A dis- cussion is given. WILLIAM E. VAUGHAN

Storage-battery electrodes, etc. I. G. FARBENIND. A.-G. Brit. 334,628, June 12, 1929. Battery manuf. as described in Brit. 211,401 (*C. A.* **24**, 790) is modified by making the hard lead parts of the battery by stamping or swaging a hard lead band made by extrusion. Various details of manuf. are described. Cf. *C. A.* **25**, 461.

Active material for storage batteries. WM. GARDINER and HENRY D. STALEY (to Vulcanite, Inc.). U. S. 1,788,571, Jan. 13. A mixt. (for pos. electrodes) formed from Ta oxide 4, Pb oxides 200 parts and an acid soln. such as H_2SO_4 is used in paste form Mo oxide, C, $Al_2(SO_4)_3$ and pumice stone may be added.

Porous metal articles such as storage-battery electrodes. I. G. FARBENIND A.-G. Fr. 690,485, Feb. 24, 1930. See Brit. 332,052 (*C. A.* **25**, 39).

Accumulators. CHARLES J. V. FÉRY. Fr. 690,580, May 1, 1929. The neg. electrode is placed horizontally at the bottom of the container, a layer of porous material covers it and the pos. electrode is mounted vertically above that.

Accumulators. JEAN M. LARGE. Fr. 689,751, Feb. 12, 1930. The electrodes of accumulators are made of little cases of insulating material perforated to a certain height, in which the Pb conductors and active material are placed.

Accumulators. KARL NAUMANN. Fr. 690,409, Feb. 21, 1930. Benzoic acid, citric acid or phosphoric acid or one of their salts is added to the active mass of the plates of elec. Pb accumulators, whereby the life of the plates is lengthened.

Accumulators. YVES LE MONIES DE SAGAZAN and PHOSPHATES ET SUPERPHOSPHATES DE TEBBAKA. Fr. 691,181, May 15, 1929. An electrolyte for Pb accumulators is composed of an aq. soln. of $(NH_4)_2SO_4$.

Accumulators. PHOSPHATES ET SUPERPHOSPHATES DE TEBBAKA. Fr. 36,869, Feb. 19, 1929. Addn. to 667,341 (*C. A.* **24**, 1042). The electrolyte is composed of an aq. soln. of H_2SO_4 contg. 65–120 g. of H_2SO_4 per l., the cupric soln. being formed after one normal charge and discharge of the battery. Cf. *C. A.* **24**, 3955.

Accumulator electrodes. I. G. FARBENIND. A.-G. Fr. 690,452, Feb. 22, 1930. Accumulator electrodes are made by submitting metal powders (preferably made from the corresponding carboxyl), mixed with an addnl. substance such as NH_4HCO_3, NaCl or C, to compression or to a heat treatment or both and then eliminating the addnl substance either wholly or in part.

Accumulator electrodes. I. G. FARBENIND. A.-G. Fr. 36,653, Mar. 16, 1929. Addn. to 644,966 (*C. A.* **23**, 1828). Electrodes for Edison accumulators having an alkali electrolyte are made of metals made by decompn. of their carbonyl compds. and used in the form of porous agglomerates.

Galvanic cells. ARTHUR GASSAN. Ger. 510,829, Oct. 30, 1928. Addn. to 495,983 (*C. A.* **24**, 3479). Further details of die-casting the Zn containers are given.

Selenium cell. "SELENOPHON" LICHT- UND TONBILDGES. M. B. H. Fr. 689,585, Feb. 7, 1930. Arrangement and connections of plates of 2 types of metals, one capable of being wetted by molten Se and the other not.

Electrodeposition of tin. SIEMENS & HALSKE A.-G. Brit. 334,738, March 28, 1929. Alk. Sn solns. contg. no plumbite or bismuthite or other not-readily-oxidizable compd. of these metals are treated with an oxidizing agent (such as O_2, H_2O_2, alkali metal or alk. earth metal peroxides or $KMnO_4$) for quant. conversion of all the Sn into stannate and the solns. are then electrolyzed without addn. of a colloid.

Electrodeposition of a coarse chromium layer on metallic surfaces. N. D. BIRYUKOV. Russ. 38,892, Jan. 16, 1929. A coarse layer of Cr is deposited on metal disks, etc., used for grinding purposes, from an electrolyte consisting of chromic acid and chromium sulfate, which compounds are introduced into a soln. of manganese chromate in strong chromic acid and of complex compds. obtained by the action of org. reducing compds on chromic acid.

Chromium electroplating. N. D. BIRYUKOV. Russ. 38,889, Jan. 16, 1929. To an electrolyte contg. chromic acid, Cr sulfate and other metals is added hydrated Pb oxide and a mixt. of Fe and Co chromates in chromic acid in a proportion of metallic cobalt, iron and lead equal to 5:1:0.6.

Chromium electroplating. N. D. BIRYUKOV. Russ. 38,898, Jan. 16, 1929. In the prepn. of a stereotype plate an electrolyte is used which contains, besides a soln. of chromic acid, Cr sulfate and Zn and Cd chromates, also a hydrate, carbonate or oxide of Ca. The proportion of metals is Ca:Zn:Mg = about 1:1:0.03.

Removing chromium plating. TRENSTEDT MANUFACTURING CO. Fr. 689,415, Feb 4, 1930. Cr plating is removed from objects coated therewith by making the object

the anode in an electrolytic bath composed of an aq. soln. of an org. acid such as oxalic, tartaric or citric acid.

Electrolyte for nickel-plating aluminum and other metals. M. O. GERSHMAN. Russ. 61,475, Dec. 31, 1929. The electrolyte is a soln. of Ni NH_4 sulfate, NH_4 lactate and $(NH_4)_2SO_4$ acidified with citric acid.

Applying abrasives to sheet materials by electrostatic precipitation on the sheets. JAMES S. SMYSER. U. S. 1,788,600, Jan. 13. Various details of app. and operation are described.

Coating electrolytic or battery electrodes. SOC. ANON. LE CARBONE. Ger. 512,341, April 26, 1923. See Brit. 206,471 (*C. A.* **18**, 1089).

Electrolysis. NADAL R. ROMULO. Fr. 691,378, Feb. 10, 1930. To obtain by electrolysis metallic compds. having low coeffs of soly. in the electrolyte, a series of vats is used in which are placed electrodes in the form of plates, the anodes being formed of the metal of which compds. are desired, and the cathodes of the same metal or of another convenient conducting substance. No membranes or diaphragms are placed between the electrodes.

Electrolytic vats. ANACONDA COPPER MINING CO. Fr. 690,437, Feb. 22, 1930. Contamination of the atm. by gas bubbles escaping from an electrolytic vat is prevented by maintaining on the electrolyte a layer of a finely divided solid substance such as ground cork, which may itself be covered with S.

Electrolyzing vessel. I. G. SHCHERBAKOV. Russ. 55,448, Sept. 28, 1929. Constructional details.

Electrolytic cell for decomposing water. ARNO E. ZDANSKI (to Bamag-Meguin A.-G.). U. S. 1,788,904, Jan. 13. Structural features.

Electrolytic cell for etching zinc or other plates. GEORGE F. JOHNSTONE. U. S. 1,788,462, Jan. 13. Structural features.

Electrolytic cell for metal deposition. IMPERIAL CHEMICAL INDUSTRIES, LTD. Ger. 512,277, Jan. 20, 1929. See Brit. 312,395 (*C. A.* **24**, 792).

Electrolytic deposition of metals. IMPERIAL CHEMICAL INDUSTRIES, LTD. Ger. 510,618, Jan. 19, 1929. Details are described of a circular cell comprising anode and cathode chambers sepd. by a filter diaphragm.

Electrolytic production of salts and alkalies such as ferrous chloride and sodium hydroxide. PETER FIREMAN (to Magnetic Pigment Co.). U. S. 1,788,512, Jan. 13. A soln. of an alkali metal salt such as NaCl is electrolyzed in the presence of a cathode and of an anode such as Fe; the bodies of the salt soln. in contact with the anode and cathode are sepd. by an independent body such as an electrolyte in an intermediate compartment which is constantly renewed without contacting the anode or cathode; the salt soln. is separately supplied to the soln. bodies in contact with the anode and cathode. App. is described.

Electrolytic refining plant for silver and other precious metals. SIEMENS & HALSKE A.-G. (Victor Engelhardt, Georg Eger and Herbert Hein, inventors). Ger. 512,172, May 7, 1928. Details of the arrangement of the anodes are described.

Drying electrolytic iron, etc. INTERNATIONAL STANDARD ELECTRIC CORP. Ger. 512,115, Aug. 9, 1927. Pulverulent, electrolytically prepd. magnetic metals, especially Fe to be used in making cores for Pupin coils, are washed with water, treated with a volatile liquid, *e. g.*, EtOH, to displace the water, and then dried.

Aluminum. COMPAGNIE DE PRODUITS CHIM. ET ÉLECTROMÉTALLURGIQUES ALAIS, FROGES ET CAMARGUE. Fr. 691,336, May 21, 1929. In the prepn. of baths used in the fabrication of Al by electrolysis, the cryolite is partly or wholly replaced by a mixt. of Al fluoride dry or damp, and NaCl or KCl. Cf. *C. A.* **25**, 647.

Nitric acid. GUTEHOFFNUNGSHUTTE OBERHAUSEN A.-G. Fr. 688,602, Jan. 21, 1930. Compds of N and O for the manuf. of HNO_3 are made by passing mixts. of N and O through a high-frequency elec. field which is created in a controlled circuit of high-frequency elec. oscillations of very high tension. Substances having a catalytic action are used, preferably as intermediate electrodes, in the high-frequency elec. field.

Phosphoric acid (electrolytic purification). I. G. FARBENIND. A.-G. Brit. 334,790, Feb. 20, 1929. The process described in Brit. 319,656 (*C. A.* **24**, 2679) is modified, when the crude acid contains an insufficiency of heavy-metal salt, by adding to the acid, before refining, a small quantity of a Cu salt (preferably Cu phosphate) in order to promote deposition of the As present (presumably as Cu arsenide). The Cu should not exceed 10% of the quantity of the As present and is preferably only 25–40% the quantity of the As. The temp. is maintained at about 50° by the working current or by external heating.

Ozone. VITTORIO GAMBAROTTA. Fr. 689,677, Feb. 10, 1930. An app. is de-

scribed for producing ozone by the action of elec. waves, in which one of the armatures is placed outside and the other inside a closed vessel.

Purifying hydrocarbons. ABRAHAM ESAU. Fr. 690,342, Feb. 20, 1930. Air, water, etc., are eliminated from solid or liquid hydrocarbons by submitting them to the action of an elec. field of high frequency or of a condenser or of a solenoid field.

Purifying liquids by electrodialysis. FILTRES PHILIPPE. Fr. 689,674, Feb. 10, 1930. Liquids are purified by electrodialysis in a vat having 3 compartments; the central compartment is traversed by the liquid to be purified and the side compartments (anodic and cathodic) are traversed by a washing liquid, the said compartments being sepd. by porous membranes. The flow of liquids in the compartments is detd to give optimum yield for a const tension of elec. current.

Chemical reactions using high-frequency currents. I. G. FARBENIND. A.-G. Fr. 691,099, Mar. 5, 1930. In carrying out reactions (such as the production of O_3, oxides of N or NH_3, the formation of acids by oxidation, etc.) by means of high-frequency currents, the elec. consts. of the generator of oscillations of high frequency and of its coupling elements are so chosen that strongly deformed oscillations are necessarily produced, comprising in each period a long pause of current. The reaction chamber is either a space, acting as condenser, placed between the generator and the vibratory circuit or in the circuit itself, or a space situated in the condenser of a coupled circuit, preferably harmonized.

Recording electric currents by color reactions. ROBERT POLLAK-RUDIN. Ger. 512,411, Dec. 4, 1928. See Brit. 301,749 (*C. A.* 23, 4309).

Liquid electric resistance. A. A. SHAPOSHNIKOV and V. A. SUKODSKII. Russ. 41,858, Mar. 1, 1929. A liquid elec. resistance having two electrodes of the same material is prepd. by dissolving Br or I in the electrolyte.

Loading wire or tape for electric conductors. STANDARD TELEPHONES & CABLES, LTD., G. LAWTON and W. H. DEARDEN. Brit. 334,547, May 31, 1929. A magnetic material is used, on the surface of which is an exceedingly thin layer of a material of higher resistivity, such as C, a nitride or Cr, *e. g.*, a layer produced by treatment with NH_3 or hydrocarbons or by a cementation process with ferro-chrome, the layer being diffused into an underlying layer, the permeability of which is at least as great as that of soft iron at low-flux ds. Also, an Fe-Ni alloy may be coated successively electrolytically with Ni and with Cr and then heated to 1000–1200°.

Electric furnaces. EMIL F. RUSS. Fr. 690,195, Feb. 19, 1930. An arrangement of suspended heating resistances is given.

Electric furnaces. ELECTRIC FURNACE CO., LTD. Fr. 689,999, Feb. 14, 1930. Construction of inductors is given.

Electric furnaces for treating metals. VICTOR SORREL and LOUIS A. LAFONT. Fr. 36,999, June 3, 1929. Addn. to 641,635 (*C. A.* 23, 1066).

Electric furnace functioning continuously for reheating or for chemical reactions. LOUIS VENNIN. Fr. 689,955, April 29, 1929.

Electric induction furnaces. GUILLIAM H. CLAMER. Fr. 690,231, Feb. 19, 1930.

Electric induction furnace for smelting ores. HERMANN ZEPERNICK. Ger. 510,599, Nov. 20, 1927. Details of construction.

Induction furnace for fusing metals. HIRSCH, KUPFER- UND MESSINGWERKE A. G. Fr. 689,754, Feb. 12, 1930.

Electric resistance oven for heating articles to be tempered, etc. L. W. WILD and WILD-BARFIELD ELECTRIC FURNACES, LTD. Brit. 334,621, June 11, 1929. A centrifugal fan effects circulation of air within the oven, various structural details being described.

Electric shaft furnace for treating waste metals and oxygen or sulfur ores. JOHANN HALÁSZ. Fr. 689,874, Feb. 14, 1930.

Melting metals in the electric furnace. K. G. WENNERSTRÖM. Brit. 334,201, May 28, 1929. In melting metals such as waste Cu, brass or Al, or heating molten [illegible] means of a slag layer by passing current through it, the entire charge is situated above the slag layer during the entire treatment. Various details of process described; a slag may be used which is lighter than the charge but has a [illegible] p. so that the surface of the slag may be kept in solid condition.

[illegible]s-distributing device for electric gas cleaner. SIEMENS-SCHUCKERTWERKE A.-G. (Richard Heinrich, inventor). Ger. 512,129, Oct. 31, 1925.

Hanging electrode for electric gas cleaners. METALLGES. A.-G. (Kurt von Eberhard, inventor). Ger. 510,199, May 24, 1929.

Furnace electrodes. SIEMENS & HALSKE A.-G. (Otto Rönitz, inventor). Ger. 512,055, June 1, 1929. A protective device is described for furnace electrodes nor-

mally kept in place by a source of power. The device acts so as to prevent the electrodes from falling into the furnace if the source of power fails.

Furnace electrodes. SIEMENS-PLANIAWERKE A.-G. FÜR KOHLEFABRIKATE. Ger. 512,499, Jan. 22, 1927. Details are given of a method of renewing self-baking electrodes while they are in use.

Carbon electrode. MERRILL J. DORCAS (to Canadian National Carbon Co., Ltd.). Can. 307,403, Jan. 6, 1931. A C electrode has a core formed by baking a mixt. of CaF_2 40, SrF_2 10, Na or K silicate 5, C flour 45 parts and tar sufficient to bind.

Electrodes for arc lamps. K. N. PUZANKOV. Russ. 60,096, Dec. 11, 1929. The elec. resistance of electrodes is increased by pressing them from a mixt. contg. 60–65% moist retort carbon and 40–35% NaCl.

Arc-lamp electrodes. PAUL GRAVIER and COMPAGNIE LORRAINE DE CHARBONS D'ELECTRICITÉ. Ger. 510,227, Sept. 15, 1929. Occluded air and other gases are removed from the electrode mass, before it is compressed, by rinsing when cold or warm with a liquid or a vapor, *e. g.*, steam. A vacuum may then be applied. App. is shown.

Quartz lamp for analysis. QUARZLAMPEN-GES. M. B. H. Fr. 689,989, Feb. 14, 1930.

5—PHOTOGRAPHY

E. P. WIGHTMAN

Reflection and transmission of light by photographic plates. D. BRENT MCRAE and R. C. TOLMAN. *J. Optical Soc. Am.* **20**, 565–72(1930).—The reflecting power and transmission for red, green, blue and "actinic" light were detd. for unexposed Eastman 40 plates. The method used was a photographic one, approx. monochromatic light being obtained by the use of Wratten filters. It was found that the reflection and transmission varied with wave length in the same general manner as did the photographic sensitivity of the emulsion. G. SILBERSTEIN

Mechanism of the formation of the latent photographic image. A. P. H. TRIVELLI. *Nature* **126**, 760(1930). —It is pointed out that the larger a Ag speck (so long as it is below a size at which development is spontaneous) the less is the amt. of Ag required to be added to it to produce developability. Viewed in this way the objections of Toy and Harrison (cf. *C. A.* **24**, 5650) may be overridden. E. W. H. S.

The **latent photographic image.** R. HILSCH AND R. W. POHL. *Nachr. Ges. Wiss. Göttingen, Math.-physik. Klasse* No. **2**, 176–8; *Z. Physik* **64**, 606-22(1930).—The no. of nuclei of the latent photographic image is related as $1:10^7$ to the no. of original AgBr mols. Because of this low concn. they are optically invisible in the AgBr layers of the dry plate. They become visible, however, in a quite transparent AgBr crystal of a few mm. thickness. The absorption spectrum of the latent image forms a band with a max. at 690 mμ. A. P. H. TRIVELLI

Photochemistry of mercuric iodide. LÜPPO-CRAMER. *Phot. Korr.* **65**, 97–100 (1929). Except for Lüppo-Cramer, only F. Kropf (*C. A.* **4**, 2911; **8**, 1710) appears to have published any work on the photochemistry of HgI_2 in gelatin. The present paper, in part, describes a repetition (and confirmation) of some of the author's earlier expts. Red HgI_2 (with gum arabic) in a gelatin film is light- and color-sensitive, the latent image being developable in alk. amidol or metol-hydroquinone. After a preliminary uniform exposure to white light, a wedge exposure to the same light source gives early and extensive "bleaching-out" (reversal) followed by re-reversal of the highest wedge exposures; the onset of these effects can be further hastened by phenosafranine. The Schwarzschild phenomenon (intensity more effective than time) is strongly marked, and the latent image itself fades rapidly, almost disappearing in about 5 hrs. E. R. BULLOCK

Luminescent surfaces (Fr. pat. 689,925) **3.**

Verarbeitung **der photographischen Platten, Filme und Papiere. Ausführliches** Handb. d. **Phot. Bd. III, Tl. 2.** 6th ed., edited by JOSEF M. EDER AND H. LÜPPO-CRAMER. Halle (Saale): W. Knapp. 388 pp. M. 30; bound, M. 32.

Photography. JOS-PE FARBENPHOTO-GES. M. B. H. Ger. 512,476, Feb. 21, 1929. See Brit. 319,077 (*C. A.* **24**, 2390).

Color **photography.** GIOVANNI ALIFREDI. Fr. 688,615, Jan. 21, 1930. Natural

colors are produced directly by the use of a single negative obtained without a screen. The negative is obtained by using a panchromatic plate and an appropriate color filter consisting of a perfect crystal. This negative is printed on an appropriate support, *e. g.*, a blue lithographic stone previously prepd. by a sensitizing soln. and developed, after which the various colors are selected by appropriate solvents and appear clearly on the matrix.

Color photography. ARTHUR TRAUBE. Fr. 689,977, Feb. 14, 1930. In the production of color photographs the reliefs in tanned gelatin are colored and absorbed by coloring solns. of a specific degree of dispersion, the prepn. of these solns. being effected by decompn. of polydispersed solns., particularly azo solns. The colored reliefs are submitted to a complementary treatment with distd. water, and, if necessary, with swelling agents such as glycolic acid. The reliefs may be regenerated by oxidizing agents destroying the colors.

Color photography. WILFRED T. L. BECKER and LESLIE W. OLIVER. Ger 510,010, April 19, 1929. See Brit. 317,909 (*C. A.* **24**, 2071).

Color photography. I. G. FARBENIND. A.-G. (Bruno Wendt, inventor). Ger. 499,481, June 5, 1929. Photographic pictures in two or more colors are produced with the use of esters and ester salts of leuco compds. of dyes as light-sensitive substances. A compd. having an oxidizing action in light, *e. g.*, an org. nitro compd., may be used as an accelerator. The carrier for the light-sensitive substance may be a colloid that hardens when exposed to light, *e. g.*, gelatin.

Screens for color photography. J. N. GOLDSMITH and SPICERS, LTD. Brit. 334,243, May 30, 1929. In forming multicolor screens upon a support of celluloid, cellulose acetate or similar compns., a greasy resist contg. a dye is applied, as by printing, to the surface of a film in a series of lines or in a geometrical pattern; the dye migrates from the resist into the surface of the film so that after removal of the resist, as by a solvent, a colored series of lines or a pattern remains on the film. Various details of compns., etc., are given.

Multicolor screen for color photography. J. N. GOLDSMITH, T. T. BAKER, C. BONAMICO and SPICERS, LTD. Brit. 334,265, June 1, 1929. The surface of a film of cellulose or celluloid or other suitable cellulose deriv. is made receptive to dyes by applying to it a layer of cellulose acetate without dye-inhibiting addns.

Photographic emulsions. KODAK PATHÉ (SOC. ANON. FRANÇAISE). Fr. 689,246, Feb. 1, 1930. New compds. suitable for photographic emulsions as sensitizers are prepd. by condensing the quaternary salts of 1-methylnaphthothiazole with ethyl orthoformate in dry pyridine. A discussion as to the mol. structure of the compds. and their intermediate products is given. In an example, the bromide of 2,2′-diethyl-5,6,5′,6′-dibenzothiocarbocyanine is prepd. by converting β-naphthylamine to 1-methyl-α-naphthothiazole, 2 mols. of which or of its halogen derivs. are condensed with 2 mols. of ethyl-*p*-toluenesulfonate by heating them together to 100° for 6 hrs. The crude product is dissolved in boiling pyridine; ethyl orthoformate is added and the mixt. heated under reflux. The dye is pptd. as bromide by adding excess of NH_4Br in aq. soln. and is recrystd. from MeOH. Another example is given.

Photographic emulsions. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 690,646, Feb. 25, 1930. A photographic emulsion is composed of a colloid, particles of photographic Ag salts and a stabilizing compd. of the type R-X-NH-Y-R, in which R is an org. radical free from N, and X and Y chosen from among the electroneg. radicals may be carbonyl, sulfuryl and imide N groups. Examples are diacetamide, phthalimide, pyrrol, succinimide, saccharine, pyrazolonic rings, pyrazolic rings, etc. Fr. 690,647 describes a similar emulsion in which the stabilizing compd. is chosen from among the group of substituted carbamides, cyclic carbamides, acid amides, substituted acid amides and amidohydrazides.

Photographic layers. KALLE & Co. A.-G. (Hermann Neuroth, inventor). Ger. 510,165, Oct. 22, 1929. Light-sensitive layers are prepd. by bringing aryl azides onto a support together with phenols, aromatic amines or aminophenols. Development of the exposed layer is effected by washing out the unreacted azide or by rendering it inactive, *e. g.*, by reduction. Examples are given. Cf. *C. A.* **24**, 3187.

Photographic diazo copies. KALLE ET CIE. A.-G. Fr. 687,956, Feb. 15, 1929. Photographic diazo copies are stabilized by adding S compds. to the light-sensitive layer, particularly derivs. of thiocarbonic acid. Examples are given of the use of thiourea.

Fixing bleaching layers containing basic dyes. I. G. FARBENIND. A.-G. Fr. 690,386, Feb. 21, 1930. Layers contg. basic dyes are fixed so that they may be rendered colorless in a subsequent operation, by treating them, after exposure to light

under a negative, with a soln. of HBF_4 or one of its salts in a solvent which dissolved the sensitizer contd. in the layer. During this operation the dyes are transformed into their insol. fluoborates while the sensitizer is dissolved. Thus, a layer of gelatin which contains anilidoflavinduline chloride sensitized by thiosinamine is exposed to light under a negative and washed with a 12% aq. soln. of $NaBF_4$ and then with weaker solns. of $NaBF_4$.

Bleach-out color films. I. G. FARBENIND. A.-G. Fr. 689,122, Jan. 30, 1930. Bleach-out color films contain basic oxonium dyes free from N with the exception of anthocyanosides Examples are the chloride of 3,6-dihydroxy-9-phenylxanthoxonium and the ethers and the chloride of 3, 6-dimethoxy-9-*o*-carbomethoxyphenylxanthoxonium.

Photographic film rolls. I. G. FARBENIND. A.-G. Brit. 334,206, May 27, 1929. Protective paper backing-strips or leader-strips are rendered unnecessary by printing non-actinic-ray-excluding coloring material over the rear of the film at its ends and over its entire width, for which purpose compns. may be used insol. in usual photographic developing baths, *e. g.*, compns. such as are described in Brit. 287,124 (*C. A.* 23, 349), Brit. 295,383 (*C. A.* **23**, 2113) and Brit. 295,578 (*C. A.* **23**, 2113).

Producing designs on surfaces composed of cellulose derivatives. I. G. FARBENIND A.-G. Fr. 689,007, Jan. 28, 1930. Designs, etc., are produced on surfaces composed entirely or partly of cellulose derivs. by incorporating in the surface products which are capable of changing, under the influence of light, the phys. or chem. properties of the cellulose derivs., exposing the layers to light under a negative and rendering the image visible by an appropriate treatment. Thus, acetylcellulose is dissolved in acetone and a soln. of $Na_2Cr_2O_7$ in MeOH is added. The mixt. is applied in a thin layer on a sheet of glass, dried and exposed to light under a negative. The development is effected by acetone in which the unexposed parts remain sol., and the image remaining is colored by appropriate dye solns. Other examples are given.

Apparatus for developing photographic prints such as diazotypes with ammonia, etc. F. C. FUKE and OZALID CO., LTD. Brit. 334,555, April 5, 1929. This pat. covers subject-matter similar to that of Brit. 331,823 (*C. A.* **25**, 45).

Photographic papers. I. A. KHOKHRENKOV. Russ. 43,109, Mar. 20, 1929. A soln. of diazo compds. and Cu salts in HPO_3 is used to treat photographic paper.

Sensitized paper. LÉONID STAROSTIN. Fr. 689,318, Jan. 28, 1929. Diazo compds. prepd. with org. acids such as oxalic acid instead of mineral acids are used for making sensitized paper. Oxidizing substances or substances having an oxidizing effect by the action of light may be used jointly with the diazocompds.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Germanium. VIII. The sulfides of germanium. WM. PUGH. *J. Chem. Soc.* 1930, 2369–73; cf. *C. A.* **24**, 2391.—A method of prepg. GeS direct from GeO_2 is developed. Thus, GeS is obtained from GeO_2 and H_2-H_2S mixts. (1–3 vols. H_2/vol. H_2S) at 700°, traces of GeS_2 in the product being removed by pulverizing, digesting overnight with cold dil. NH_3, and drying. Cryst. GeS_2 is slowly produced by the action of S vapor on GeO_2 at 850°, and is formed quite rapidly by heating (700–800°) GeO_2 in a current of H_2S and S vapor. Some of the properties of GeS and GeS_2 are described.

J. BALOZIAN

Isomorphism among oxides of quadrivalent metals. The systems: CeO_2–ThO_2, CeO_2–ZrO_2 and CeO_2–HfO_2. L. PASSERINI. *Gazz. chim. ital.* **60**, 762–76(1930).—The expts. continue similar investigations of isomorphism in oxides of metals of lower valency, the results of which have been recently published for binary systems of tervalent metal oxides (*C. A.* **25**, 633). Besides the chief object of the work, which is devoted to the problem of isomorphism, attention was also devoted to the cubic form of HfO_2 and ZrO_2. The existence of a monometric modification of these oxides is established for ZrO_2 but not for HfO_2 except by analogy in the similar chem. behavior of Hf and Zr. However, solid cubic solns. between ZrO_2 and HfO_2 were obtained, in which each oxide was dissolved in a greater proportion of the other oxide; therefore it was possible to det. the dimensions of the cell of the cubic modification of HfO_2 and thus to est. the diam. of the Hf^{++++} ion. The oxides were prepd. by calcination, at approx. 800°, of solid solns. of the hydroxides, which had been pptd. by KOH from calcd. quantities of the nitrates or sulfates. The systems CeO_2–ThO_2, CeO_2–ZrO_2 and CeO_2–HfO_2 were then examd. by x-rays (with the powder method). They consist of solid solns. which,

like CeO_2 and ThO_2, crystallize in the cubic system with a lattice structure of the fluorite type. In the CeO_2–ThO_2 system, the components are sol. in all proportions, and the lattice consts. and the d. are proportional to the compn. of the solid solns. In the CeO_2–ZrO_2 and the CeO_2–HfO_2 systems the soly. is only partial. The max. proportions dissolved are approx. 27% CeO_2 in ZrO_2 and 23% ZrO_2 in CeO_2, and 25% CeO_2 in HfO_2 and 32% HfO_2 in CeO_2. These limits are slightly greater than the limits for the bivalent and tervalent metal oxides, where the difference in dimensions of the metal ions is equal to that between the Ce^{++++} and Zr^{++++} ions. From the solid solns. obtained it was possible to calc. by extrapolation the lattice dimensions of the cubic form of ZrO_2 and of the probable cubic form of HfO_2. These were for ZrO_2: $a = 5.065 \pm 0.01$ A. U., $v = 129.94 \times 10^{-24}$ cc., d. 6.27; for HfO_2: $a = 5.115 \pm 0.01$ A. U., $v = 133.82 \times 10^{-24}$ cc., d. 10.43. The 2 oxides have a lattice of the fluorite type, with a calcd. diam. of the Hf^{++++} ion of 1.79 A. U. The solubilities in the solid state of the quadrivalent metal oxides are qualitatively similar to those of the bivalent and tervalent metal oxides, insofar as the soly. is an inverse function of the ratio between the dimensions of the metal ions in any system. Quantitatively, however, the soly. differs in that the limits of soly. between the quadrivalent metal oxides are slightly higher than those of the oxides of the metals of lower valency. Consequently, the ratios between the diams. of the metal ions which delimit the solubilities (total and partial solubilities and insolv.) are 1–2% different from those of the bivalent and tervalent metal oxides. C. C. Davis

Use of oscillating discharges in the formation of some gaseous hydrides. B. Foresti with Mario Mascaretti *Gazz. chim. ital.* **60**, 745-54(1930).—The expts. are closely related to the ground-breaking expts. of Paneth and his collaborators (cf. P., *C. A.* **13**, 1043, 1430; **15**, 350; **17**, 2238; P. and Winternitz, *C. A.* **13**, 1431; P. and Fürth, *C. A.* **14**, 1494; P. and Nörring, *C. A.* **15**, 213; P. and Matthies, *C. A.* **16**, 2088; P., M. and Schmidt-Hebbel, *C. A.* **16**, 2088; P. and Rabinowitsch, *C. A.* **19**, 1228; P., Haken and R., *C. A.* **19**, 1228), and deal with the formation of SnH_2, BiH_3 and PbH_2 by the use of oscillating discharges between Sn, Bi and Pb electrodes in a current of H at atm. pressure and in the complete absence of org. substances. The previous investigators had been unable to obtain any hydride unless certain org. substances were present, and their results indicated that the presence of the latter was essential to the formation of hydrides (cf. P. and Hofeditz, *C. A.* **23**, 5159; Schultze and Müller, *C. A.* **24**, 2036). Under the conditions and with the technic employed by F., however, hydrides were formed in the absence of any org. substance. The *app.*, which is described and illustrated, involved: (1) heating by a "localized" discharge (2) rapid elimination of the products and cooling the latter rapidly to room temp.; and (3) abs. absence of org. substances. Under these conditions all 3 hydrides were obtained. The best results were obtained with Sn, where the yield increased with diminution of the distance of the discharge. If the latter becomes aperiodic, the quantity of hydride becomes almost or wholly negligible. To obtain the highest yields, it is necessary, with increase in the self-induction of the circuit, to increase the capacity, and *vice versa*. This indicates that there is no relation between the yield and the period of the oscillating discharge. C. C. Davis

Boron hydrides. XIV. B_4H_{10}. Alfred Stock, Egon Wiberg and Hans Martini. *Ber.* **63B**, 2927–37(1930); cf. *C. A.* **24**, 2684.—B_4H_{10} is the principal product of the dissocn. of borides with acids. At room temp. B_2H_6 occurs also. H_3PO_3 was found preferable to the HCl formerly used (cf. *C. A.* **24**, 2684). With HCl the hydride itself gives B_4H_9Cl, and with NaHg, $2Na.B_4H_{10}$, which with H_2O gives H_2 and the hypoborate. With NH_3 (−70°) a solid white salt-like substance, $B_4H_{10}.4NH_3$, is formed, which decomposes with loss of H and NH_3 at room temp., but at 180° loses H to form $B_4N_4H_6$, for which a 6-at. ring structure is suggested. $B_4H_{10}.4NH_3$ can be chlorinated with HCl in steps at room temp. On electrolysis in liquid NH_3, NH_4 (with subsequent decompn.) is given off at the cathode and B_4H_6 at the anode. Several intermediate reactions such as the formation of $[B_4H_4(NH_2)_2]H_4$, $[B_4H_2(NH_2)_4]H_4$, $[B_4(NH_2)_6]H_4$ and their salts are indicated, leading to the conclusion that 4 of the H atoms in B_4H_{10} are different from the other 6 Gregg M. Evans

Investigations of the structure of compounds of the $MeMe_2^{\prime\prime\prime}O_4$ type. I. Cadmium and calcium indiates. L. Passerini. *Gazz. chim. ital.* **60**, 754–61(1930).—The present work is a continuation of studies of the factors on which the lattice structure and the cryst. system of $MeMe_2^{\prime\prime\prime}O_4$ compds. depend, studies which were begun with compds. of this type which crystallize in the cubic system with the lattice structure of spinels (cf. *C. A.* **23**, 4167; **24**, 4439; Natta and P., **23**, 4649; **24**, 1311). A consideration of these results and those of other investigators shows that compds. of the $MeMe_2^{\prime\prime\prime}O_4$ type can crystallize with a spinel lattice structure only for certain relations between

the at. dimensions, whereas the chem. properties have little or no influence. In the present expts., 2 hitherto unknown compds. were prepd. by calcination at 900° of mixts. of the theoretical proportions of the resp. nitrates, *viz.*, *Cd indiate*, $CdIn_2O_4$, and *Ca indiate*, $CaIn_2O_4$. Both are white powders; they were examd. by x-rays (with the powder method). They crystallize in the tetragonal system with a lattice structure of the hausmannite type (spatial group $D_4^{19}{}_h$), as judged by calcns. of the theoretical intensities of the observed lines. The elementary cells contain 8 mols. For $CdIn_2O_4$, $c/a = 1.14$, $a = 8.650 \pm 0.005$ A. U., $c = 9.875 \pm 0.007$ A. U., $v = 739.0 \times 10^{-24}$ cc., calcd. d. 7.30. For $CaIn_2O_4$, $c/a = 1.12$, $a = 8.770 \pm 0.005$ A. U., $c = 9.822 \pm 0.007$ A. U., $v = 755.5 \times 10^{-24}$ cc., d. 5.87. C. C. DAVIS

A note on the preparation of iodine trichloride. E. C. TRUESDALE AND F. C. BEYER. *J. Am. Chem. Soc.* **53**, 164–5(1931).—A convenient app. and method for the prepn. of pure ICl_3 are described. P. H. EMMETT

Rubidium and cesium nitrides. K. CLUSIUS. *Z. anorg. allgem. Chem.* **194**, 47–50 (1930).—In the decompn. of Rb and Cs azides, the residues contain the nitrides of these metals, Rb_3N and Cs_3N. They are gray, green powders, extremely sensitive to moisture, giving the following reaction: $Me_3N + 3H_2O \longrightarrow 3MeOH + NH_3$. H. S.

The other oxides of carbon. KENNETH A. KOBE. *J. Chem. Education* **8**, 232–9 (1931).—A review. E. H.

Recovery of rubidium and cesium compounds from carnallite. III. GERHART NDER AND FRANZ BUSCH. *Z. anorg. allgem. Chem.* **194**, 38–46(1930); cf. *C. A.* **24**, 84.—An artificial carnallite contg. between 0.7 and 1.0% RbCl and 0.007 and 0.01% CsCl was the raw material for these expts. 2.3 kg. was dissolved in a mixt. of 2.9 l. O and 0.9 l. concd. HCl, the soln. was warmed to 65°, and 140 cc. of silico-molybdic id was added. After distn. in a current of HCl gas and sepn of silicic acid, 3.25 of mixed chlorides was obtained. From the HCl soln. of this salt mixt., CsCl was pd directly by $SbCl_3$ in the form of a Cs-Sb chloride, and the CsCl was sepd. from the $SbCl_3$ by a HCl distn. The chloride residue so obtained contained 0.234 g. CsCl, rresponding to about 0.01% CsCl in the carnallite. In working up larger quantities this material, a further working of the silico-molybdate ppt seems desirable. This dissolved in a caustic alkali to form a soln. of simple alkali molybdates and alkali licates. If $Ca(OH)_2$ or a soln. of $Ba(OH)_2$ is used, a soln. of alkali hydroxide and a t. of poorly sol. Ca silicate and Ca molybdate or the corresponding Ba compds. are rmed. If the filtrate is satd. with CO_2 the hydroxide is converted into a carbonate; a digestion of this the carbonates of the alk. earths sep. out and the filtrate remaining contains only the carbonates of the alkalies. This method, applied to 2.3 g. of carnallite, yielded 0.23 g. CsCl and 24.3 g. RbCl, in complete agreement with he HCl distn. method. A method for recovering molybdic acid from the silico-molybate ppt. is described. H. STOERTZ

The **behavior of molybdenum pentachloride in organic solvents.** WM. WARDLAW ND HARRY W. WEBB. *J. Chem. Soc.* **1930**, 2100–6.—This study of the action of $MoCl_5$ n EtOH, Et_2O and pyridine (I) shows that it is a most reactive compd., the green solns. oing due in all cases to a reaction between $MoCl_5$ and the solvent. Analogous to the eaction between EtOH and PCl_5, dry EtOH and $MoCl_5$ react vigorously, $[NMe_2H]_3$-$MoOCl_5$] being isolated with 2-methylamine hydrochloride from the reaction soln. hild with EtOH. The coördination compd. $MoCl_5.2(C_2H_5)_2O$ (black crystals) is prepd. by mixing dry Et_2O (100 cc.) and powd. $MoCl_5$ out of contact with the air, decanting and evapg. in a vacuum. In the presence of H_2O the green $MoOCl_3$ is formed. *$MoCl_4$.-$3C_5H_5N$* (brown amorphous powder) is prepd. by reacting in a sealed vessel for 10 days $MoCl_5$ (12 g.) and dry I (250 cc.), filtering, and washing with CH_2Cl until the wash is free of I. *$MoCl_4.4C_5H_5N$* (colorless cryst. substance) deposits on allowing the preceding filtrate to stand. *$MoCl_4.5C_5H_5N$* (red orthorhombic crystals) deposits from the filtrate on prolonged standing. To explain the action of $MoCl_5$ on I it is suggested that the reaction is preceded by the formation of $C_5H_5N\langle^{Cl}_{MoO_4}$ which breaks up to form MoO_4 and C_5H_5NCl. J. BALOZIAN

Partial substitution of the oxalic acid residue in oxalate anions of bivalent metals. II. R. SCHOLDER AND CARL F. LINSTRÖM. *Ber.* **63B**, 2828–31(1930); cf. *C. A.* **21**, 3322.—The following compds. have been prepd.: $MnC_2O_4.2KNO_2.H_2O$; $2ZnC_2O_4$-$K_2C_2O_4.KNO_2.6H_2O$; $2MnC_2O_4.K_2C_2O_4.2KCNS$; $2ZnC_2O_4.K_2C_2O_4.KCNS.6H_2O$; CoC_2O_4-$K_2S_2O_8$; $MnC_2O_4.K_2S_2O_8.H_2O$; and anhyd. $ZnC_2O_4.K_2C_2O_4$. In general, this was done by the action of very concd., hot solns. of the nitrite, etc., upon the metallic oxalate.

The coördination structure of these is discussed with relation to similar ones prepd earlier. GREGG M. EVANS

Oxidation with fluorine. XVII. Preparation of pertitanic, pervanadic and permolybdic acids; reduction of peracids by ozone. FR. FICHTER AND ARON GOLDACH. *Helv. Chim. Acta* **13**, 1200–7(1930); cf. *C. A.* **24**, 4997.—Molybdic acid in HF is oxidized by F to permolybdic acid, the yield varying from 4.89 to 29.05% calcd. to the F used. Temps. from 0 to 50° were employed and periods during which F was passed into the soln. were varied from 5 to 30 min. The higher temps. and shorter duration gave the best yields. A similar soln. of TiO_2 gave 0.4–4.58% pertitanic acid, and a soln. of vanadic acid dissolved in H_2SO_4 was oxidized to the extent of approx. 1%. Ozonized O reduces H_2SO_4 solns. of the 3 per acids, this accounting for the diminution of yield with increase in duration of the oxidation expts. since ozone is formed gradually in these expts. This explanation, however, is not applicable to the F oxidation of Na metaborate in Na_2CO_3 since, although ozone reduces the perborate, the formation of ozone has never been observed under these conditions. A. WIEBEN

The true nature of per-acids and the alleged "acid nucleus theory." SHIN'ICHIRO HAKOMORI. *Bull. Chem. Soc. Japan* **5**, 333–44(1930).—A polar mol. such as H_2O or H_2O_2 may induce polarity in a particle and be held to that particle by the resulting "induction valence." Thus, an oxy-acid may be considered a combination of H_2O with an "acid nucleus," which is an element combined with O to form a stable octet For H_2SO_4 the acid nucleus is (SO_3), forming $(SO_3) \sim HOH$. *Orthophosphoric acid* may be written $(P_2O_5) \sim 3HOH$, which is unstable and breaks down to give $2H(PO_3) \sim HOH$, which in turn loses H_2O to become HPO_3 The per-acids are similar combinations of H_2O_2 with acid nuclei such as UO_3, TiO_2, MoO_3, V_2O_5 and CrO_3, which are listed in order of increasing color and constraint of electrons and decreasing stability of the per-acid formed. JANET E. AUSTIN

Purification of perchloric acid by vacuum distillation. G. FREDERICK SMITH AND O. E. GOEHLER. *Ind. Eng. Chem., Anal. Ed.* **3**, 48–52(1931).—Designs of stills for the purification of $HClO_4$ by vacuum distn. are described, including a cold-target type, the use of special designs to prevent superheating is discussed. A cold target design giving the best results is described in detail. This form of still provided the greatest degree of superheating and the best time rate of distn. The variation in the acid concn. of both distillate and residue with change in pressure over the range 1 to 7 mm. is given. The sepn. of $HClO_4$ from various amts. of H_2SO_4 and H_3PO_4 by vacuum distn. is examd. quantitatively, and the conditions under which complete sepns. are effected are described. The time rate of distn. of various designs of stills is detd. and the rate of distn. shown to be directly proportional to the degree of superheating employed. Graphs and tables accompany the paper. J. W. SHIPLEY

Dissociation of concentrated perchloric acid during vacuum distillation at moderately low pressures. New method for the preparation of anhydrous perchloric acid. O. E. GOEHLER AND G. FREDERICK SMITH. *Ind Eng. Chem., Anal Ed.* **3**, 55–8(1931). A study of the vacuum distn. of 73.3–73.6% $HClO_4$ was made over the pressure range 7–18 mm. Yields of 7–10% anhydrous $HClO_4$ were obtained without the use of any desiccating agent and under abnormally high superheating conditions. The mechanism of the distn. is explained on the basis of assuming a surface film of oxonium perchlorate, OH_3ClO_4. J. W. SHIPLEY

Oxonium structure of hydrated perchloric acid. G. FREDERICK SMITH AND O. E. GOEHLER. *Ind. Eng. Chem., Anal Ed* **3**, 58–61(1931).—**The transition** of cryst. $HClO_4$ was studied in a f.-p. app., approx. 73% $HClO_4$ being used. **Transition** with absorption of heat indicating the reaction $HClO_4.2H_2O \longrightarrow OH_3ClO_4.H_2O$ was pointed out The m. p. of oxonium perchlorate was detd. as 49.905° ± 0.005°. No evidence of the existence of $HClO_4.H_2O$ was obtained and the reaction $OH_3ClO_4 \longrightarrow HClO_4.H_2O$ probably does not occur. The construction of a density-acid concn. table over the range 70–80% is suggested in place of detg. the acid strength by chem. means. The data secured indicate an oxonium structure for all of the hydrates of $HClO_4$. J. W. S.

Oxonium perchlorate as reference standard for the construction of specific gravity-percentage composition table for strong perchloric acid solution. G. FREDERICK SMITH AND O. E. GOEHLER. *Ind. Eng. Chem., Anal. Ed.* **3**, 61–3(perchlorate, OH_3ClO_4, was prepd. and the d. of solns. covering the range 65–[illegible] detd. by the displacement method. A table of ds. covering this range of concns. is given. Const.-boiling $HClO_4$, 72.4% at 760 mm. and 203°, has the approx. d. 1.6964. The d_4^{25} $HClO_4.2H_2O$ is 1.71282. J. W. SHIPLEY

Possibility of a partial substitution of the lead halides by lead chromate in the chlorophosphates, chlorovanadates and chloroarsenates of the same metals (pyro-

morphite, vanadinite and mimetite). GUIDO CAROBBI. *Atti III congresso naz. chim. pura applicata* 1930, 341–2.—By melting together $Pb_3(PO_4)_2$, $PbCl_2$ and $PbCrO_4$ with excess NaCl, yellow hexagonal crystals of pyromorphite were obtained. Analysis gave the formula as $3Pb_3(PO_4)_2.(PbCl_2.PbCrO_4)$ with not more than 6% $PbCrO_4$. Similar procedure gave compds. $3Pb_3(VO_4)_2.(PbCl_2.PbCrO_4)$ and $3Pb_3(AsO_4)_2.(PbCl_2.PbCrO_4)$ with not more than 6% and 4% $PbCrO_4$, resp. G. M. MURPHY

Physicochemical studies of complex acids. III. Molybdic acid. HUBERT T. S. BRITTON AND WM. L. GERMAN. *J. Chem. Soc.* 1930, 2154–66; cf. *C. A.* **24**, 4477.—The reaction in aq. soln. between Na_2MoO_4 and strong and weak acids (HCl, AcOH, phenylacetic acid) is followed potentiometrically and conductometrically. To explain the results it is assumed that the Na polymolybdate first formed in HCl soln. decomposes with further addn. of HCl, giving a highly ionized polymolybdic acid, the ionization of which decreases with increase in the HCl added until finally un-ionized MoO_3 remains in soln. Weak acids decompose Na_2MoO_4 to a smaller extent than HCl, the final complex being $Na_2O.3MoO_3$, which resists further attack by the weak acid. $ClCH_2CO_2H$ gives a final Na polymolybdate intermediate between $Na_2O.3MoO_3$ and $Na_2O.5MoO_3$. IV. **The vanadates of silver.** HUBERT T. S. BRITTON AND ROBERT A. ROBINSON. *Ibid.* 2328–43.—A study of the compds. of Ag and 5-valent V, potentiometric titrations of $AgNO_3$ soln. with 3:1, 2.5:1, 1.6:1 and 1:1 $Na_2O{\cdot}V_2O_5$ (I) (and the reverse titrations) with the cell $Ag \mid 0.1\ N\ AgNO_3 \mid$ satd. $KNO_3 \mid 0.01\ N\ AgNO_3 + Na_3VO_4 \mid Ag$, and conductometric titrations of 3:1, 2:1 and 1:1 I with $AgNO_3$ solns. being described. No compds. of Ag_2O and V_2O_5 other than the 3:1, 2:1 and 1:1 could be found. If an excess of $AgNO_3$ soln. is added to a $x Na_2O.V_2O_5$ soln, then a mixed ppt. of compn. $xAg_2O.V_2O_5$ is obtained. If the I soln. in excess is added to $AgNO_3$ soln., the 3:1 $Ag_2O.V_2O_5$ is pptd. if the solute lies between 3:1 and 2:1 I, while the 2:1 $Ag_2O.V_2O_5$ is pptd. if the solute lies between 2:1 and 1:1 I. If it is assumed that the VO_4^{---} ion hydrolyzes into HVO_4^{--} and OH^- (this being confirmed by both series of titrations), const. values of the soly. product (K) of Ag_3VO_4 are detd. as: $K = [Ag^+]^3[OH^-][HVO_4^{--}] = 1.5 \times 10^{-21}$. In the 2 $Ag_2O.V_2O_5$ soln., the HVO_4^{--} ion exists rather than the $V_2O_7^{----}$ ion, giving const. values of $K = [Ag^+]^3[HVO_4^{--}] = 1.5 \times 10^{-14}$. The soly. product of $Ag_2O.V_2O_5$ is detd. as $K = [Ag^+][VO_3^-] = 4.8 \times 10^{-7}$. J. BALOZIAN

Handbuch **der anorganischen Chemie. Bd. IV, Abt. 3, Tl. 2, B. Lfg. 1. Die Elemente d. achten Gruppe d. period. Systems. Tl. 2. Eisen und s. Verbindungen.** Edited by RICHARD ABEGG, FRIEDRICH AUERBACH AND IVAN KOPPEL. Leipzig: S. Hirzel. 463 pp. M. 45.

7—ANALYTICAL CHEMISTRY

W. T. HALL

New ways **in analytical chemistry. Rapid determination of different elements according to classic methods. II.** J. DICK. *Z. anal. Chem.* **82**, 401–15(1930); cf. *C. A.* **23**, 1634.—The procedures recommended for detg. Zn as $ZnNH_4PO_4.H_2O$, Mn as $MnNH_4PO_4.H_2O$, Co as $CoNH_4PO_4.H_2O$ and Cd as $CdNH_4PO_4.H_2O$ correspond closely to those previously described except with respect to the drying and weighing of the ppts. $(NH_4)_2HPO_4$ is recommended as precipitant, 10–20 times as much as the wt. of metal cation to be detd. being used. The reagent is added to the boiling soln., which is then heated 10–20 min. on the hot-water bath. The presence of NH_4 salts is necessary in the Zn detn., does no harm in the Mn detn. but should be limited in the Co and Cd detns. The first 2 ppts. can be filtered off within half an hr. but the 2 latter should stand at least an hr. The Zn and Mn ppts. should be washed first with hot 0.1% (NH4)2HPO4 soln., the Co ppt. with hot 0.5% $(NH_4)_2HPO_4$ and the Cd ppt. with cold 0.1% $(NH_4)_2HPO_4$ soln. Then, to remove sol. PO_4^{---} the Zn ppt. is washed with water and the Mn, Co and Cd ppts. are washed with 65% alc. All ppts. are then washed with 95% alc. to remove water and lastly with ether. Finally air is drawn through the porcelain filtering crucible or it is dried in a vacuum; this final treatment constitutes the principal change in the procedure and the only shortening of the time needed. Ppts. with detg. Se as metal after pptn. with SO_2, of Te as metal after pptn. with an alk. soln. of *d*-glucose and of Cu as CuSCN show that in these cases also the drying in the hot closet can be omitted and considerable time saved. W. T. H.

Effect of ammonium chloride upon the results in the determination of magnesium by the method of B. Schmitz. J. MAJDEL. *Z. anal. Chem.* **82**, 425–9(1930).—The expts. described show very clearly that in the detn. of Mg as $Mg_2P_2O_7$ correct results

can be obtained when 20 times as much NH_4Cl as Mg is present, but the results are likely to be low with very little excess NH_4 salt present or with too much NH_4Cl. W. T. H.

New method for determining traces of chromium in steel. W. J. AGNEW. *Analyst* 56, 24–8(1931).—Dissolve 1 g. of sample in 15 cc. of 9 *N* H_2SO_4 and 20 cc. of water, finally oxidizing the Fe^{++} with 5 cc. of concd. HNO_3. Boil free from HNO_3 and make up to 200 cc. Take 40 cc. of the soln., add 3 drops of satd. $KMnO_4$ soln., boil 5 min., destroy excess $KMnO_4$ with concd. HCl added dropwise until the soln. becomes clear (about 50 drops). Cool, ppt. the Fe as hydrated oxide by a slight excess of satd. Na_2CO_3 soln., dil. to 100 cc. and filter. Take 50 cc. of the filtrate, add 20 cc. of 9 *N* H_2SO_4 and 5 cc. of 0.1% diphenylcarbazide soln. Compare the resulting color with that obtained with standards contg. known quantities of Cr. The results obtained with 0.0017–0.051% of Cr added to electrolytic Fe show an abs. check to 2 significant figures in 36 out of 38 analyses in the presence of Cu, Ni, Mo, V, W and Co. W. T. H.

Determination of potassium as potassium perrhenate. HANS TOLLERT. *Naturwissenschaften* 18, 849(1930).—The detn. of K as $KReO_4$ is advocated. The method is analogous to the $KClO_4$ method, with the following advantages: Less reagent need be employed, the perrhenic acid is non-volatile, the mol. wt. of the perrhenate (289.4) is favorable and Re can be re covered by reduction in H_2. B. J. C. VAN DER HOEVEN

Detection and determination of nickel with dimethylglyoxime in the presence of considerable cobalt. F. FEIGL AND H. J. KAPULITAS. *Z. anal. Chem.* 82, 417–25 (1930). The detection [illegible] of Ni as well as the detn. of the quantity

therefore, dissolve 0.0–1.0 g. [illegible] in 2–3 cc. of water, and treat with concd. KCN soln. till the cyanide ppt. redissolves. Add H_2O_2 to the hot soln. until a honey yellow color shows that $Co(CN)_6^{---}$ has been formed, evap. to a small vol. and add an excess of (*A*). To the luke-warm soln. (50–60°) add formaldehyde dropwise until an excess is shown by the smell. Shake with 1–2 cc. of ether to get the characteristic film between the 2 layers. The ppt can be weighed. From the aq. soln. pure *Co salt free from Ni can be prepd.* W. T. H.

Some tests for zirconium. F. PAVELKA. *Mikrochemie* [n. s.] 2, 345–51(1930). Zr gives many characteristic color reactions with org. substances. In this paper tests with carminic acid (*A*), gallocyanin (*B*), (*B*) together with arsenate (*C*) and (*B*) together with *m*-nitrobenzenearsonic acid (*D*) are described. The reagent (*A*) is yellow in acid soln. but gives with Zr a coloration resembling MnO_4^- in color. To the acid soln (0.4 *N* in HCl) add some (*A*) (dissolved in sufficient 30% alc. to give a wine red color) and heat on the water bath. To detect traces of Zr use only enough of (*A*) to give a slight yellow tint to the acid soln. The reagent (*B*) is pink in dil. acid solns. but turns blue if Zr is present. Add to 1 cc. of the sample, 0.2–0.3 cc. of 2 *N* HCl and enough of the aq. soln. of (*B*) barely to give a pink coloration in a blank test with dil. HCl. If Al, Th, Be or Ce is present, the tested soln. should contain 10% of concd. HCl. Ti interferes. To sep. Zr from Th, Moser and Lessnig (*C. A.* 19, 2180) have recommended pptg. the Zr as arsenate. When such a ppt. is formed in the presence of (*A*) or (*B*), highly colored ppts. are formed and it is easy to detect smaller quantities of Zr than are pptd by arsenate alone. To the soln. to be tested, add a little solid (*B*) and 0.2–0.3 cc. of 2.4 *N* HCl. Heat nearly to boiling, add 1 cc. of 4% Na_2HAsO_4 soln. and heat a little while on the water bath. Dil. with half as much alc. to dissolve the excess reagent and boil a min. Filter to see if any blue ppt. has been formed in the violet soln., using an Emich filtering rod, wash any ppt. with 1 cc. of hot alc. and dry if necessary. The presence of Al and Be does no harm but, when Ce is present, more acid is required. With *m*-nitrobenzenearsonic acid alone, a few drops of its dil., aq. soln. is added to the test soln. to which 0.2–0.3 cc. of concd. HCl has been added. A strong turbidity at once appears and the ppt. coagulates on heating the liquid. Al, Ce, Be and Th do not interfere but Ti must be absent. The pptn. with reagent (*D*) is effected similarly except that a tiny crystal of (*B*) is added before heating. Finally the ppt. should be filtered off as with (*C*). This test succeeds in the presence of Al, Ce and Be but more acid is required in the presence of Th. and Ti must be absent. The test with (*A*) can be carried out effectively as a spot test on good filter paper. W. T. H.

Determination of phosphorus in steel, alloy steels and cast iron. A. T. ETHERIDGE. *Analyst* 56, 14–21(1931).—The method recommended by E. is essentially that of J. O. Handy and depends on the formation of NH_4 phosphomolybdate and alkalimetric

titration of the ppt. after suitable washing. The details differ slightly from the directions commonly followed in the steel labs. of the U. S. The notes on the effect of Ti, Si, Cr, V and W are helpful. No analytical results are given. W. T. H.

Microchemical detection of certain heavy metals by drop tests with dithizone (diphenylthiocarbazone). HELLMUT FISCHER. *Mikrochemie* **2**, 319–29(1930); cf. C. A. **24**, 567.—Dithizone, in even as low concn. as 1–2 mg. per 100 cc., gives a bright-green color in CCl_4 soln. If such a soln. is shaken with an aq., approx. neutral soln. contg. salts of heavy metals, a characteristic color change is noticeable. The reaction can be carried out in spot tests on paper, on a tile or in a small test tube. The tests for Cu, Pb, Ag, Zn and Co are described. A yellow-brown color is obtained with Cu and thereby a very small quantity is detected in the presence of Pb, Zn, Cd and Ni. The Cu test is best made in neutral or very slightly ammoniacal soln. A brick-red color is obtained with Pb; in alk. solns. contg. KCN very small quantities of Pb can be detected in the presence of Ag, Cu, Ni, Zn, Cd and Sb. A fine, violet ppt. is obtained with Ag and in slightly alk. soln. traces of Ag can be detected in the presence of Pb, Zn and Sb. A purple-red color is obtained with Zn, a stronger soln. of reagent being desirable; the test can be obtained in AcOH soln. buffered with NH_4OAc in the presence of Ni, Cd and Al but Ag, Hg, Cu and any considerable quantity of Co interfere. A reddish violet color is obtained with Co in 2% NH_3 soln. and the test succeeds in the presence of Ni. To detect Co in the presence of Zn, a 2% NaOH soln. is advisable the color produced is at first bluish violet fading to a nearly colorless gray. Of these tests, those for Cu and Pb are to be recommended especially. W. T. H.

The analysis of various alloys. ETTORE DI NOLA. *Ann. chim. applicata* **20**, 601(1930).—Alloys of Cu-Zn and Cu-Zn-Ni may be analyzed rapidly and volumetrically by detg. the Cu by the Volhard method, the Ni by the use of dimethylglyoxime, the Zn by difference. A. W. CONTIERI

Analysis of ferro-silicon. G. H. GOODWIN. *Analyst* **56**, 21–4(1931).—To det. Si, fuse 1 g. of fine powder with 10 g. Na_2CO_3 and 5 g. Na_2O_2 in a Ni crucible. Ext. the fused mass with hot water and, when completely disintegrated, transfer to an evapg. dish, add an excess of HCl and evap. to dryness. Bake 2 hrs. at about 110°, take up in 20 cc. of 6 *N* HCl and heat 5 min. on the water bath. Add 150 cc. of hot water and filter immediately, washing the ppt. with 5% HCl. Then ppt. $Fe(OH)_3$ by adding a slight excess of NH_4OH, filter, dissolve the ppt. and evap. with HCl, repeating the treatment as before but using only 10 cc. HCl to take up the residue and washing the SiO_2 recovered with cold 1% HCl. Add this ppt. to that originally obtained and continue in the usual manner. W. T. H.

Detection of chlorates in the presence of perchlorates and nitrates. THEODORA P. RAIKOW AND KOWACHEWA. *Z. anal. Chem.* **82**, 415–7(1930).—If about 1 g. of the fine powder is treated with 5 cc. of freshly prepd. H_2S water, a turbidity due to S appears within 1 sec. and in 1–3 min. makes the soln white and opaque. Perchlorates do not show this reaction and it takes at least 10 min. for the same quantity of nitrate to show any effect. As little as 0.01 mg. of $KClO_3$ in 0.1 cc. of soln. gives the turbidity test with 5 cc. of the aq. H_2S. W. T. H.

Local detection of phosphides in metal sections. M. NIESSNER. *Mikrochemie* **2**, 94–6(1930).—Polish the section with the finest emery paper, be sure that all grease is removed and immerse for 30 sec. in a cold, satd. Ag_2SO_4 soln. contg. 0.1% free H_2SO_4 by vol. Wash off the deposited Ag by a strong stream of water and wipe repeatedly with cotton. Then treat with a 0.03% soln. of *p*-dimethylaminobenzylidenerhodanine in acetone. Adding to the reagent, just before using it, half as much of 6 *N* H_2SO_4. After 2 min. remove the specimen and wash off excess reagent by dipping in acetone and finally in ether. Dry in the air and examine under the microscope. The test is shown to give characteristic results in detecting P inclusions in Cu alloys. The assumption that S prints show evidence of P inclusions as well as of S is shown to be erroneous. W. T. H.

Note on the Denigès-Personne method (of potassium iodide analysis). JACINTO PLACERES. *Anales oficina quím. provincia* **3**, 104–7(1929).—In the assay of KI by titration with 0.2 *N* $HgCl_2$ the sample should be dissolved in less than 10 cc. of H_2O or the result may be too low. Titration in hot soln. is best. Enough $NaHCO_3$ should be added to neutralize any acid present in the $HgCl_2$ soln. L. E. GILSON

Determination of small amounts of hydrogen sulfide. W. V. HARSHMAN, D. A. MCPHERSON AND F. H. EDMISTER. *J. Elisha Mitchell Sci. Soc.* **46**, 54–61(1930).—Expts. were made to test the accuracy of various methods and suggestions are given for obtaining greater accuracy. No method was found sufficiently accurate for detg. H_2S produced by microörganisms. A. L. MEHRING

The reaction between nitrite and aminosulfonic acid. FRIEDRICH L. HAHN AND PAUL BAUMGARTEN. *Ber.* **63B**, 3028–9(1930); cf. *C. A.* **24**, 3727.—If the nitrite in a 4% soln. is destroyed by aminosulfonic acid, 0.004 mg./cc. of nitrate is found in the nitrite-free soln. After pptn. with 2,4-diamino-6-hydroxypyrimidine the filtrate shows 0.002 mg./cc. of nitrate. The diphenylamine test in the presence of chloride is sensitive to 0.0001 mg./cc. It is therefore pos. in either case but the $FeSO_4$ test is pos. only after concn. to 4% and 2%, resp., of the original vol. B. A. SOULE

Hydroxyquinoline and its usefulness in the determination of certain cations. E. CATTELAIN. *J. pharm. chim.* [8], **11**, 484–96(1930); cf. *C. A.* **20**, 1365.—The chem. nature and synthesis of the reagent (*A*) (Skraup, 1882) and the chem. compn. and properties of its compds. with metals are reviewed (cf. Fox, *C. A.* **4**, 2937; Mörner, *C. A.* **16**, 3527). The pptg. behavior of *A* (*e. g.*, in 2% alc. soln.) toward salts of 23 metals in either AcOH-AcONa, tartro-ammoniacal or tartro-alk. medium is tabulated, also the sensitiveness of pptn. for Cu, Mg, Zn, Cd, Al, Bi, U, Mn, Fe^{+++}, Co and Ni. The use of *A* in qual., gravimetric and volumetric analysis and sepn. of the metals is then briefly reviewed, based on the work of Berg (*C. A.* **21**, 799 (Br method), 1237 (outline), 1778, 2449, 2630, 3849–50 (Cu, Mg, Zn, Cd, Al); **22**, 1929 (Bi); **23**, 1588 (Fe, Mn, Ni, Co); **24**, 4479 (Ti)), Hahn, *et al.* (*C. A.* **21**, 244, 2632 (Mg, Zn, Al, Cu)), Niessner (*C. A* **23**, 1589 (Be)), Marsson and Haase (*C. A.* **23**, 1077 (Pb)), etc. A list of 23 references is added. S. WALDBOTT

Simple method for detecting traces of hydrochloric acid in the presence of hydrobromic acid. G. G. LONGINESCU AND TH. I. PIRTEA. *Bull. sect. sci. acad. roumaine* 13, 195–6(1930).—First ppt. all the halogen by adding an excess of $AgNO_3$. Filter off the ppt. and wash it with water till all excess Ag is removed. Then pour a little 6 *N* NH_4OH through the filter several times; this should dissolve the AgCl much more readily the AgBr. To the ammoniacal soln. add 1 cc. of 0.1% KBr soln., make acid with HNO_3 and filter. To the filtrate add a little $AgNO_3$; if a white ppt. of AgCl is obtained it is certain that the original ppt. contained at least 1 mg. of AgCl W. T. H.

New rapid method for the determination of the nitric acid radical in medicinal subnitrates. LEONOR S. VILLEGAS DE BOLLINI. *Anales oficina quím. provincia* **3**, 96–103 (1929).—Dissolve 0.1 g. of Bi subnitrate in 5 cc. H_2O and 2 cc. concd. H_2SO_4 and dil. to 100 cc. Mix 10 cc. of this soln. with 20 cc. concd. H_2SO_4 and titrate with a 1/40 soln. of indigotin sulfate. The end-point color change varies from dark bottle green to violet with different samples of indigotin sulfate and is detd. when the soln. is standardized against pure KNO_3. L. E. GILSON

Spot tests for acetic acid and for propionic acid. D. KRÜGER AND E. TSCHIRCH. *Mikrochemie* **2**, 337–8(1930); cf. *C. A.* **24**, 2083, 5002.—The characteristic blue colorations with basic La salt and I_2 can be used for spot tests. As reagents use (*A*) 5% $La(NO_3)_3.6H_2O$ soln., (*B*) 0.01 *N* I in alc., (*C*) *N* NH_4OH. Place a drop of the neutral soln. to be tested on the porcelain spot plate, add a drop of (*A*), a drop of (*B*), mix and add a drop of (*C*). Around the drop of (*C*) a blue or bluish brown ring is formed if acetic or propionic acid is present. W. T. H.

Quantitative analytical study of the simultaneous production of thiol acids (R-S-H) and sulfonic acids ($R-SO_3H$) from dithio acids (R-S-S-R) by silver sulfate. PAUL W. PREISLER AND DORIS B. PREISLER. *J. Biol. Chem.* **89**, 631–45(1930); cf. Vickery and Leavenworth, *C. A.* **24**, 2723.—Ag_2SO_4 reacts with $COOH.CH_2SSCH_2.COOH$, dithiodilactic acid, cystine and $COOH.(CH_2)_2SS(CH_2)COOH$ to produce iodine-reducing substances and some free sulfide. Three mols. $NaOOC.(CH_2)_2SS(CH_2)_2.COONa$ react with 5 mols. $Ag_2SO_4 + 3H_2O$ to give $5AgOOC(CH_2)_2SAg$ (I) + $5NaHSO_4$ + $NaOOC(CH_2)_2SO_3H$, (II), thus being more readily reduced by Ag_2SO_4 than by $CrCl_2$, (Preisler, *C. A.* **24**, 5023). (I) was identical with the Ag salt prepd. from thiohydracrylic acid and was unstable at 80°. (II) was crystd. as the Ba salt + $5H_2O$. K. V. THIMANN

Toxicological detection of barbituric acid derivatives. H. KAISER. *Pharm. Monatshefte* **11**, 271(1930); cf. *C. A.* **24**, 4732.—An address. W. O. E.

Defecation of extraction liquids obtained in toxicology. P. CHERAMY AND F. LAGARCE. *J. pharm. chim* [8], **12**, 366(1930).—Emulsifying matter (lipoids, fatty acids, biliary salts) in exts. obtained by the Stas-Otto-Ogier method may be largely eliminated by adding a slight excess of a 10% soln. of $BaCl_2$ to the aq. soln. of the alc.-tartaric residue, excess $BaCl_2$ being removed by means of dil. H_2SO_4. This method is specially useful in the toxicol. extn. of barbituric derivs. (cf. Lang, *C. A.* 24, 5110). S. WALDBOTT

Combustion arrangement for the acid method of determining iodine in organic products. G. PFEIFFER. *Biochem. Z.* **228**, 146–53(1930).—In the oxidation of org.

matter by means of H_2SO_4 and H_2O_2 a difficulty is encountered in the fact that volatile fatty acids escape in the distn. and are absorbed in the alkali. This is now prevented by inserting a short quartz tube contg. Pt gauze coil between the flask in which the org. matter undergoes oxidation and the absorption bottles. The tube is kept at red heat by means of an elec. heater. The I_2-contg. combustion gases are absorbed in K_2CO_3 soln. For 10 g. of dry substance the first bottle is filled with 5 cc. satd. K_2CO_3 and 5 cc. H_2O; the second bottle, with 1–2 cc. K_2CO_3. However, where as much as 1–2 γ I_2 is expected per cc. of absorption fluid, KOH may be used instead of K_2CO_3. The alkali, together with the wash water, is used for the I_2 analyses. A suitable aliquot, perhaps 10 cc., is transferred to a small Erlenmeyer flask, mixed with freshly prepd. Cl water and acidified with HCl dild. 1:1. The Cl_2 water should be added until the acidified mixt. smells strongly of Cl_2. This is now kept boiling vigorously 3–4 min. and cooled; the liberated I_2 is titrated with 0.002–0.001 *N* $Na_2S_2O_3$ after adding a few drops of 0.2% starch soln. and a few crystals of KI. If, however, a preliminary qual. test fails to show demonstrable amts. of I_2 in the collected fluid, this is to be evapd. and finally brought to dryness in a 250-cc. porcelain dish. The residue which must be pure white is rubbed with a pestle and worked into a thin mass with a few drops of H_2O. This is extd. with alc., the ext. evapd. to dryness in a porcelain dish. Only when this is still colored by admixture of org. matter is the residue transferred to a Pt dish and carefully ignited over a free flame. The residue is now available either for a titrimetric or colorimetric I_2 detn. S. MORGULIS

Micro iodine determination in organic substances. L. SCHEFFER. *Biochem. Z.* 228, 4–20 36(1930).—The ashing of the org. substance is carried out on the sand bath, 1–2 or 5 g. dry substance being completely ashed in 3–6 hrs. with an excess of KOH. The ash is treated with 2 cc. satd. I_2-free $(NH_4)_2CO_3$ soln. to convert all the KOH into K_2CO_3, the NH_4OH is driven off on the water bath and the crucible again heated on the sand bath for 5–10 min. To the ash moistened with a few drops of H_2O is added 2.5 cc. alc., this washing with alc. being repeated. The alc. ext. contains all the I_2. It should be evapd. cautiously without boiling, any residue of org. matter being ashed once more with a few drops of KOH for 10–30 min. It is important that the ash should be first taken up in a little water before the alc. extn. is attempted. The I_2 is estd. from the residue by means of CCl_4 after the elementary I_2 is set free by oxidation with HNO (Rosenthaler's method). For this purpose the ash is dissolved in warm H_2O and the soln. is filtered into a 30-cc. separatory funnel. This is acidified with 5% HNO_3 and after adding 2 drops of 5% $NaNO_2$ is extd. 4 times with 1-cc. quantities of CCl_4. Only HNO and not H_2SO_4 should be used for acidifying. The combined CCl_4 exts. are poured into 0.4 cc. 4 *N* H_3PO_4 contg. 0.4 cc. satd. $CaCl_2$ soln. and mixed well until the violet color of the CCl_4 disappears. This amt. of reagent is enough for 50 g. of I_2; other wise larger quantities must be used. On adding 4–5 cc. H_2O, the mixt. is boiled down to about 2–3 cc. The water-clear soln. after cooling is now titrated from a microburet with 0.002–0.005 *N* $Na_2S_2O_3$. One or two crystals of solid KI are added before the titration. S. MORGULIS

Iron activity. V. The benzidine reaction. A. SIMON AND TH. RIETZ. *Z. anorg. allg. Chem.* 194, 89–112(1930); cf. *C. A.* 23, 4113.—The activity of Fe compds. is characterized by at least 3 reactions: the ordinary benzidine reaction as used in the common test for blood; an influence on bacterial growth; absorption of O. The purpose of the present work was the application of the benzidine reaction in studying differences in activity between Fe^{II} ions and complex Fe^{II} salts, and its use as a quant. measure of this activity. The Fe compds. studied were $Fe(HCO_3)_2$, $FeCl_2$, $Na_3[Fe(CN)_5H_2O]$, $Na_2[Fe(CN)_4.H_2O]$, hemoglobin and Na Fe tartrate. Preliminary quant. tests indicated that the benzidine test gave neg. results in either strongly acid or strongly alk. solns., the max. p_H being 3.95. Fe^{II} ions give a less permanent blue color in this reaction than the complex Fe^{II} salts, hemoglobin or blood, because of the destruction of this blue color by oxidation, which takes place more rapidly in the presence of simple Fe^{II} ions than in soln. of complex Fe^{II} salts. The intensity of color in the benzidine is thus little suited as a measure of the catalytic activity of these Fe compds. A study was made with the object of using the amt. of benzidine consumed as an indication of the activity of the Fe. It was first necessary to develop a method for accurate detn. of benzidine in both alc. and H_2O solns. This was as follows in alc. soln.: After the Fe salt has completed its action, 3 times the vol. of H_2SO_4 is added and the pptd. benzidine sulfate filtered out. It is washed twice with 0.3% Na_2SO_4 soln. and finally with H_2O. The filter and ppt. are then suspended in 100 cc. of H_2O, vigorously shaken and titrated boiling hot with KOH and phenolphthalein. In H_2O solns. the method is essentially the same except that in addn. to the H_2SO_4 at least 35 cc. of alc. must be

added for every 100 cc. of soln. These methods gave good results on known solns.; this should then afford a means of quantitatively estg. the catalytic action of Fe compds. H. STOERTZ

Method of analyzing mixtures of hydrogen, methane and ethane. MLLE. E. M. J. MULDERS AND F. E. C. SCHEFFER. *Rec. trav. chim.* **49**, 1057–65(1930).—M. and S. have devised a *rather simple method of analyzing mixts. of* H_2, CH_4 *and* C_2H_6. The basis of the method is as follows: At the temp. of liquid air, H_2 is above its crit. temp., whereas CH_4 and C_2H_6 are solids with low vapor tensions. At −190° CH_4 has a vapor tension of 2.5 cm. of Hg; that of C_2H_6 is negligible. A mixt. of these 3 gases when condensed at −190° may contain solid CH_4, solid C_2H_6, liquid (H_2 + CH_4 + C_2H_6) and gas (H_2 + CH_4). When the pressure is diminished by means of a pump, the gas (H_2 + CH_4) is removed, the liquid is changed into solid C_2H_6 and gas (H_2 + CH_4), the solid CH_4 evaps., while the solid C_2H_6 remains in the cooled tube. The mixt. of the 3 gases is thus sepd. into 2 fractions, each of which contains only 1 or 2 gases. The analysis is carried out as follows: The mixt. of the 3 gases is passed through a tube cooled with liquid air. Some of the material condenses; a vacuum is then created by means of a Hg pump and the vol. of the gas obtained is measured. This fraction (I) contains all the H_2 in the sample and all, or nearly all, of the CH_4. The solid in the tube is then vaporized by removing the liquid air bath, and the vol. of the gas is measured. This fraction (II) consists of all the C_2H_6 and either no CH_4 or only a slight quantity of it. The gas in I is then oxidized by passing it several times through a tube contg. CuO heated to redness. A small quantity of O_2 is set free from the CuO, but is made to recombine with the Cu by passing the gases back and forth through the CuO tube at a lower temp. The CO_2 formed is measured in a buret; the H_2O is absorbed by P_2O_5. Fraction II is then oxidized and the products are measured as before. From the vols. measured, the compn. of the original mixt. may be calcd. The results obtained showed that the sepn. of H_2 and C_2H_6 is quant., but that the sepn. of CH_4 and C_2H_6 is not quant., since solid C_2H_6 retains some CH_4 either by absorption or by occlusion. A better sepn. of these 2 gases is obtained by repeated vaporization and condensation. The presence of H_2 diminishes the absorption of CH_4 by C_2H_6. M. and S. state that the method gives exact results, even when the work is done rapidly. L. K

Microanalytical determination of methoxyl groups. GERTRUDE M. WARE. *Mikrochemie* **2**, 352–5(1930).—In detg. methoxyl groups by the micro-Zeisel method, the results are invariably low, chiefly because of (1) loss of AgI as a result of incomplete reaction of the alkyl iodide with the alc. $AgNO_3$ soln. and (2) incomplete reaction between HI and the dissolved substance. To overcome these difficulties the substance can be introduced in pellet form and HI of d 1.96, instead of d. 1.50, used. Pass CO_2 into $AgNO_3$ soln. to remove traces of sulfide, then through a precision stopcock into concd. H_2SO_4 and finally through a wash bottle which is ¾ filled with a suspension of red P in 10% $CdSO_4$ soln. W. T. H.

New method for the volumetric determination of methoxy- and ethoxy-groups. II. Microanalysis. F. VIEBÖCK AND C. BRECHER. *Ber.* **63B**, 3207–10(1930); cf. *C. A.* **25**, 474.—A 3–5 mg. sample is treated with HI and P in a modified Pregl app. The absorption flask is charged with AcOH-acetate mixt. contg. 2–3 drops of Br_2. After heating and passing CO_2 through the system 20–30 min., the soln. in the receiver is poured into an acetate soln. Excess Br_2 is destroyed with HCOOH. The addn. of KI and then H_2SO_4 gives I_2, which is titrated with $N/30$ $Na_2S_2O_3$. Data show the accuracy of the method. B. A. SOULE

Detection of glucose and lactose. LIVIO PAVOLINI. *Chim. ind. agri. biol.* **6**, 411 (1930).—Glucose and lactose reduce the Schweitzer soln.; when glucose is present, the CH_2O ppts. as a red-brown flaky deposit (hydrogel), while when lactose is present, the soln. becomes turbid, but the Cu_2O remains in colloidal soln. (hydrosol). G. A. BRAVO

New test for methylglyoxal in the biochemical splitting of sugars. CARL NEUBERG AND MAX SCHEUER. *Ber.* **63B**, 3068–72(1930).—One mol. hexose, as H_2PO_4 ester, yields 2 mols. methylglyoxal in the presence of *B. lactis aerogenes*. 1,2-Naphthylenediamine reacts with this methylglyoxal to form 3-methyl-α,β-naphthoquinoxaline, which may be extd. with ether and crystd. If HCl is present with ether, colorless prisms of $C_{13}H_8(NH_2)_2.2HCl$ are formed, m. 267°. The free diamine crystals easily darken in moist conditions. On sublimation *in vacuo*, white glistening laminae result, m. 95°. MARY E. LEAR

Detection and determination of pyridine. S. B. TALLANTYRE. *J. Soc. Chem. Ind.* **49**, 466–8T(1930).—A discussion involving the methods of sepg. the pyridine bases, with special reference to pyridine. Detection with aq. CNBr-PhNH$_2$ [illegible]

bright yellow color with 1 part C_5H_5N in 350,000. Other methods are mentioned and references given. Detns. by pptn. with phosphotungstic acid and with silicotungstic acid are described. G. R. YOHE

Determination of nicotine in commercial solutions and insecticides. A. SABATIÉ. *Ann. fals.* **23**, 544–7(1930).—It is recommended that the nicotine be detd. by 3 methods: (1) steam distn. over calcined MgO or NaOH, 250 cc. of distillate being collected without concn. of the soln., and a further 250 cc. while concg. the soln., and then polarizing the 2 distillates separately; (2) titration with 0.1 *N* acid in the presence of methyl red indicator; (3) pptn. with Bertrand's reagent (K silicotungstate) in HCl soln., the ppt. being weighed after drying at 120° and also after igniting, with the factors 0.1011 and 0.1139, resp. When the soln. is adulterated with C_5H_5N the Bertrand method and the titration with acid give too high results; when it is adulterated with NH_4OH titration with acid gives too low results. A. PAPINEAU-COUTURE

Colorimetric method for determining turpentine oil in the atmosphere. I. M. KORENMAN. *Z. anal. Chem.* **82**, 429–38(1930).—The colorimetric detn. of turpentine-oil vapors in the air by absorbing in EtOH and further treatment with vanillin-HCl is shown to be inaccurate. Attempts to improve the accuracy did not prove successful. Considerable information concerning the colors obtained with various concns. of turpentine under different conditions is given in a 2-page table. W. T. H.

Quantitative Analyse. Tl. 2. Gewichts-Analyse. 4th ed., edited by ERNST OBER. Leipzig: John. Ambr. Barth. 85 pp. M. 3.

Colorimetric analysis. PETER WULFF. Ger. 510,760, Dec. 17, 1927. Addn. to 405,091. In or on the "indicator foil" (cf. *C. A.* **21**, 3855), specified in Ger. 405,091, are provided substances (*e. g.*, esters whose acid radicals are to be freed within the foil in a subsequent operation) which "topochemically" hold the materials that are to react in the foil with the formation of a ppt., and thus localize the reaction in or on the foil. The colorimetric detn. of a sol. Fe salt by the formation of an alkali salt of $H_4FeC_6N_6$, using a cellulose xanthate foil, is described.

8 MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

The vanadium content of acid earths and minerals. SATOYASU IIMORI. *Bull. Inst. Phys. Chem. Research* (Tokyo) **9**, 852–4 (Abstracts 82–3 (in English) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, No. 271–3)(1930).—V has been detd. in a no. of Japanese acid earths and minerals such as mica, clay, pumice, sandstone and rhyolite. The V content of the acid earths is between 0.0041 and 0.018% V_2O_5. Evidence is given to show that the oxidase-like action of the acid earths in the indophenol reaction is not due to structural characteristics but to the presence of small amts. of Mn or Ce; V and Fe do not give this reaction. J. B. AUSTIN

New observations on quartz. R. WEIL. *Compt. rend.* **191**, 935–7(1930); cf. *C. A.* 24, 5002. **25**, 243.—Further observations on etching with HF indicate that type "*S*" differs from type "*L*" in showing "hairs" on the etched surface instead of canals. Solution with HF placed in holes in the quartz showed formation of negative crystals in the case of *L* and complete disintegration with *S*. R. S. DEAN

The hydrated calcium silicates. I. The system CaO–SiO_2–H_2O. VALDIMAR A. VIGFUSSON. *Am. J. Sci.* [5], **21**, 67–73(1931).—The system CaO–SiO_2–H_2O includes a no. of rare natural minerals such as hillebrandite, foshagite, afwillite, xonotlite, riversideite, crestmoreite, gyrolite, reyerite, centrallasite and okenite. The hydrated minerals are compared as to compn. and with the corresponding anhyd.

compds. All the hydrated Ca silicates except foshagite and centrallasite have compns. involving simple ratios of $CaO:SiO_2$. The compds. having a 1:1 ratio are most numerous and may be considered the most stable. The sp. gr. decreases with increasing H_2O and decreasing proportion of CaO. **II. Hillebrandite and foshagite.** *Ibid* 73-8.—X-ray data show that hillebrandite and foshagite have the same crystal structure. Differences in the chem. compn. of the 2 minerals are most likely due to partial hydrolysis and carbonation of foshagite. The sp. gr. of foshagite is 2.67, slightly less than hillebrandite. The optical properties of the 2 minerals are similar. Differences in *n*s are probably due to the presence of a thin film of amorphous SiO_2 on the fibers of foshagite

ALDEN H. EMERY

The computation of the probable value of ore reserves from assay results. S. J. TRUSCOTT. *Bull. Inst. Mining Met* No. 315, 25-6(1930); cf. *C. A.* **24**, 4737; 25, 265.—Discussion. ALDEN H. EMERY

Mineral industry of Alaska in 1929. PHILIP S. SMITH. *U. S. Geol. Survey Bull.* **824A**, 1–109(1930). E. H

The gold resources of Alaska. PHILIP S. SMITH. *Econ. Geol.* **25**, 176–96(1930) - A history of production with map of districts and tables showing lithology and methods of mining in various districts It is unjustifiable to give a precise est of the lode Au, but the probable reserves are very large. ALICE W. EPPERSON

A metallographic study of some metallic minerals of Jugoslavia. ST. PAVLOVITCH *Compt. rend.* **191**, 720–2(1930).—The principal minerals of Jugoslavia are the Cu ores and the Pb-Ag-Cu ores. The characteristic of the latter class, as evidenced by metallographic examn., is the const. presence of tetrahedrite, the cause of the ores' richness in Ag. This characteristic has been found by others in analogous ores elsewhere. A brief report is made of the examn. of ores of both classes. ALICE W. EPPERSON

Sequence of ore deposition in north Idaho. ALFRED L. ANDERSON. *Econ. Geol.* **25**, 160–75(1930); cf. *C. A.* **24**, 2085, 4737.—Copper veins are invariably accompanied by a dolomite gang, and were earlier depositions than the Pb-Ag veins which are accompanied by siderite. These 2 classes of veins probably owe their distribution to differences in thermal conditions along fissures during deposition, Cu being deposited earlier and at higher temp. than Pb and Ag, and deposited during the interval in which the more insol. dolomite and ankerite were pptd. The Pb, Zn and Ag remained in soln longer and were concd. along with the Fe to be later pptd. as sulfides in assocn with a siderite gang. Formation of the Cu veins is a complex process, while that of the younger Pb-Ag veins is simpler, involving only 2 stages. ALICE W. EPPERSON

Origin of the Boleo copper deposit, Lower California, Mexico. M. E. TOURWAIDE. *Econ. Geol.* **25**, 113–44(1930).—T. discusses general, structural and historical geology of the deposit, its origin and the ore beds. The deposit consists of 4 mineralized clay beds, interstratified in volcanic tuffs and conglomerates. Cu was carried into the clay beds by diffusion, and there pptd. as chalcocite by H_2S or a similar product of org. decompn. Plasticity of the clay allowed crystal formation. Native Cu was also pptd. in some parts of the district. The deposit can be defined as a stratified deposit of primary chalcocite and native Cu, formed by concn. of Cu contained in the surrounding rocks by means of circulating waters. Tables are given showing compn. of the ore.

ALICE W. EPPERSON

Copper deposits on the Arctic Coast of Canada. GORDON C. DUNCAN. *Can. Mining J.* **52**, 34–5(1931).—Coppermine River area on the north coast of Canada was explored during the summer of 1930. No important tonnage of native Cu was located, but rich sulfides of Cu, chalcopyrite and bornite were found in very encouraging surface showings. W. H. BOYNTON

The copper shale of Mansfield. J. W. GREGORY. *Bull. Inst. Mining Met.* No **315**, 28 pp.(1930).—The ore is a thin bed (av. 9 in.) of bituminous marly shale contg. 2.7–3.2% Cu. The distribution of values is very irregular. The origin of the ore is discussed. G. believes it is syngenetic. Cu was originally pptd. from soln. as carbonate The source of the Cu was probably the lodes in the Hartz Mts. The $CuCO_3$ was later altered to bornite. ALDEN H. EMERY

Iron in Bermuda. W. L. R. EMMET. *J. Maryland Acad. Sci.* **1**, 235–8(1930). — The island is built of coral rock which is white and nearly free from siliceous matter and Fe. The fertile soil found in the valleys and in pockets has a deep red color. Analyses of the rock and soil, resp., are: H_2O 0.316, 6.930; org. matter 3.806, 14.910; sand 0.050, 20.100; $Al_2O_3 + Fe_2O_3$ 0.520, 51.550; CaO 52.470, 3.334; MgO 1.686, 0.091; K_2O 0.064, 0.155; Na_2O 0.243, 0.055; CO_2 42.866, 0.767; SO_2 0.206, 0.060; Cl 0.020, 0.042; P_2O_5 0.077, 0.620%. According to E.'s theory this red Fe-bearing material is of meteoric origin. W. L. HILL

Origin of chromite. F. E. KEEP. *Econ. Geol.* **25**, 219–21(1930).—A discussion of the papers of Sampson and of Ross (*C. A.* **24**, 40). ALICE W. EPPERSON

Molybdenite deposit at Shakan, Alaska. A. F. BUDDINGTON. *Econ. Geol.* **25**, 197–200(1930).—The ore carries from 1.0 to 2.28% MoS_2. The deposit affords evidence as to the position of molybdenite in the succession of sulfide deposition: it was deposited in 3 successive mineralizations at different temps. ALICE W. EPPERSON

The absence of gypsum in calamine deposits of Sardinia. CARLO CHINAGLIA. *Resoconti assoc. miner. sarda* **35**, No. 6, 28–9(1930).—The absence of $CaSO_4.2H_2O$ in the deposits of Zn minerals shows that the calamine is not formed by oxidation of the blende, as in the blende-smithsonite deposit of Dezzo (Lombardy). G. A. BRAVO

Tin-bearing pegmatites in eastern Manitoba. DUNCAN R. DERRY. *Econ. Geol.* 25, 145–59(1930).—Tin occurs as cassiterite in eroded pegmatite dikes. The most favorable places for segregations of possible economic value are in the roofs of pegmatite bodies not yet exposed by erosion, but which may be picked up by drilling or underground exploration. Geologic history and commercial possibilities are discussed. ALICE W. EPPERSON

Supergene cassiterite in Bolivian tin veins. JOSEPH T. SINGEWALD, JR. *Econ. Geol.* 25, 211–8(1930).—S. takes issue with the theory advanced by Koeberlin (*C. A.* 25, 266) that ore shoots in many Bolivian Sn mines are due to "soln. of cassiterite in the upper parts of the veins; downward percolation; re-deposition as tin oxide at lower levels." Contrary evidence is presented. ALICE W. EPPERSON

Mercury in New Zealand. T. A. BLACK. *Chemist and Druggist* **112**, 50, 648, 708; 113, 405–6(1930); cf. *C. A.* **17**, 1203. S. WALDBOTT

Gallium, germanium, indium and scandium. ALICE V. PETAR. Bur. Mines, *Information Circ.* **6401**, 17 pp.(1930).—P. gives a description of these 4 metals under the following headings: properties, history, occurrence, uses, production, list of dealers, markets and prices, metallurgy. A 5-page bibliography is included. A. H. E.

Occurrence, stratification, origin and formation of German rock salt (Zechstein) deposits. E. KÜHNEWEG. *Naturwissenschaften* **18**, 925–31(1930).—A review with several diagrams of the salt deposits of Germany with geological and chem. details. B. J. C. VAN DER HOEVEN

Greensand bibliography to 1930 (annotated) with a chapter on zeolite water softeners. R. NORRIS SHREVE. Bur. Mines, *Bull.* **328**, 78 pp.(1930).—The literature on the manufacture of K_2O and other chemicals from greensand, on the use of greensand and zeolites as H_2O softeners is classified and abstracted. ALDEN H. EMERY

The witherite deposit of the Settlingstones Mine, Northumberland. G. TRESTRAIL. *Bull. Inst. Mining Met.* No. **315**, 10 pp.(1930).—The deposit consists chiefly of a grayish crystalline mass of witherite with some transparent nearly pure $BaCO_3$. Accessory minerals are not uncommon. Calcite frequently occurs, galena infrequently, strontianite sporadically. Niccolite, together with crystals of ullmannite, were once found assocd. with $Sb_2Pb_2O_7$ in a pocket of galena. ALDEN H. EMERY

The diamond deposits on the upper Araguaya River, Brazil. FREDERICO W. FREISE. *Econ. Geol.* **25**, 201–7(1930).—The geography and geology of the district are described. The diamonds occur as hexoctahedra and tetrahexahedra. Discussion of possible origin, working and future prospects is given. Characteristic minerals occurring as satellites and their frequency of occurrence are listed. ALICE W. EPPERSON

The origin of coal. E. BERL, A. SCHMIDT AND H. KOCH. *Z. angew. Chem.* **43**, 1018–23(1930).—In earlier work (*C. A.* **22**, 3292) B. and S. discussed the behavior of cellulose on treating with water under pressure; in a similar way in the present study both lignin and pine wood were treated with water at 350°. By suitable pressure at a temp. of 200–250°, a hard product similar to lump coal is obtained. Charred lignin is a brittle coal. Difference in properties is thought to be due to the quantities of soluble extractable material. Cellulose coal gives tar rich in phenolic compds., and on dist. yields more tar that the lignin coal. These N- and S-free tars have the same constituents as natural coal tars. Cellulose coal is not identical with lignin coal. It is possible to prepare a coal from cellulose identical in properties with natural coal. By higher alk. concn. of the charring medium, a viscous asphalt-like product is obtained, indicating that the p_H of the medium of coal formation was greater than 7, and that the cause of clinkering of coal is the alkalinity of the medium in which the cellulose was charred. It is established that charring with water converts cellulose to cellulodextrin, hydrocellulose, glucose and the like. Similarly, by charring bituminen-forming constituents of brown coal, products resembling montan wax are obtained. Probably hard coal has its origin chiefly in lignin-poor plants. It is not thought that clinkering coals originate from albuminous material, since charring of albumin gives

an oil instead of a coal. Brown coal has been chiefly formed from wood containing lignin as well as cellulose. ALICE W. EPPERSON

Geology of the oil fields of Baku. R. SCHREITER. *Allgem. österr. Chem. Tech.-Ztg.* **48**, 111–5(1930).—The 3 oil fields at Baku, the most important in Russia, are compressed into a limited space in the peninsula of Apscheron. The dozens of sand deposits filled with oil are nowhere extensive. The dome-shaped anticline stretches from northwest to southwest, its sides sloping at 18–20°. The productive surface of the dome is about 4 sq. km. in area. The Balakhany-Sabunchy-Romany field, surrounded by Pliocene limestone rocks like Bibi-Eibat, has a productive surface of about 15 sq. km. Petroleum fills the loose sands and shale to a depth of 2500 ft. The frequent folds and wrinkles make boring difficult. This field especially is characterized by lenses of oil sands. The anticline of the third field, Surakhany, runs from north to south. Near the summit of the anticline, all the sands contain gas. Even at depths of 20 to 30 ft., gas is obtained in abundance and is used for lime-burning. In the region where the Aktschagyl layer (Upper Miocene) arches up, many sands from below 650 ft. contain considerable amts. of white oil, sp. gr. 0.785. The dark-colored oils (sp. gr. 0.820) are found more in the fresh-water formation. The stratigraphy is detailed in 4 tables. EMMA E. CRANDAL

The nature of the siliceous rocks of the spur of the mountain of Valenius. M. G. FILIPESCO. *Bull. sect. sci. acad. roumaine* **13**, No. 6, 158–62(1930).—The Carpathian Oligocene strata are composed of siliceous rocks of diatomaceous origin, deposited in the sea, as indicated by the presence of diatoms in glauconite. In the strata of sandstone of Kliwa, the constituents of the sandstone have been carried by the sea, the wind and waves. The silica of diatomaceous earth was the source of silica for silication. It is generally admitted that diatoms contain drops of oil which may be transformed to hydrocarbons, and diatoms multiply so rapidly to form so many individuals that it is possible that they could furnish the org. material from which, by a physico-chem. process, hydrocarbons are produced. The opinion of other authors is confirmed that the menilitic strata are those of the primary formation of petroleum. At Monterey (California) it has been concluded that the parent rock of the oil formation is represented by a diatomaceous earth, and that the substance of these organisms has given rise by natural distn. to the hydrocarbons. ALICE W. EPPERSON

Contribution to the petrography of Kamchatka. F. YU. LEVINSON-LESSING. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, 1–6(in English).—New analyses of lavas from the old collections of Ditmar and Postels are given. Comparative study of these analyses shows a great variety of lavas of Kamchatka, as regards chem. compn. A brief microscopic description of some of the specimens is given, showing that most of the lavas are characterized by the presence of basic plagioclase phenocrysts, basaltic hornblende as colored constituent and vitrophyric texture. Lavas containing pyroxene (light green augite) are rare; rhombic pyroxene has not been found. The basaltic rocks of Kamchatka are in the main like the basalts of Etna, in regard to their acidity coefficient and alkalinity, in which respect they differ from av. Hawaii lavas. In Fe content and alkalinity, lavas of Kamchatka are more like the lavas of Etna, both belonging to the alk type of basalts. ALICE W. EPPERSON

Retrogressive metamorphism and phyllonitization. ELEANORA B. KNOPF. *Am. J. Sci.* [5], **21**, 1–27(1931).—To demonstrate reversal in metamorphism, the rock must be caught in the act of changing from one set of characteristic minerals to another and it must be possible to prove that the change is retrogressive, as in the case of garnet or biotite that has altered to chlorite. A *phyllonite* is a rock of phyllitic appearance, formed by the mylonitic degradation of an originally coarser-grained rock. A. H. E.

Secondary salt-dome materials of the coastal plain of Texas and Louisiana. MARCUS A. HANNA. *Bull. Am. Assoc. Petroleum Geol.* **14**, 1469–75(1930).—Anhydrite, residual after the leaching of impure salt, is hydrated to gypsum and converted to calcite and S with minor amts. of galena, sphalerite, hauerite and barite. "Burned" cores of granular gypsum and coarse selenite have changed to satin-spar. One replacement of selenite by S is discussed. ALDEN H. EMERY

The origin of desert varnish. J. D. LAUDERMILK. *Am. J. Sci.* [5], 21, 51–66 (1931).—Lichens growing on rocks having a Mn and Fe content secrete acids which corrode the outer layers of the rock surface. The resulting soln., bearing dissolved mineral matter, is absorbed and elaborated by the lichen. Part of the dissolved Fe and Mn salts are pptd. on the surrounding rocks as hydroxides. As the growth of the lichen progresses, a point is reached when the plant is checked by the accumulation of Fe and Mn oxides, and eventually dies. Through the decompn. of the org. matter, acids are generated which dissolve or peptize the oxides. During the rainy season,

capillary action distributes them on the surrounding surface and also carries them to other rocks which may have no Mn. During the dry season the intense heat completes the transformation of the hydroxides or other compds. to anhyd. desert varnish.

Milling methods and costs at the Copper Queen concentrator of the Phelps Dodge Corporation, Bisbee, Ariz. E. WHITTENAU AND W. B. CRAMER. Bur. Mines, *Information Circ.* 6404, 29 pp.(1931).—The Copper Queen Concentrator treats 4000 tons of ore daily by flotation. During 1929, heads averaged 2.15% Cu; recovery was 91.32%, the concentrates contg. 12.92% Cu. The ore is a porphyry carrying Cu mainly as chalcocite, which is very finely assocd. with pyrite, in a siliceous gang. Au assays 0.006 and Ag 0.12 oz. per ton. The approx. mineralogical compn. of mill heads in 1929 was: chalcocite 2.32, chalcopyrite 0.07, covellite 0.13, bornite 0.03, native Cu trace, tenorite 0.02, cuprite 0.02, unspecified oxides 0.13, pyrite 19.11 and gang 78.17%. Costs of treating 1,445,425 tons of ore to produce 219,991 tons of concentrates in 1929 were (in cents per ton of ore): crushing and conveying 5.9, primary grinding 11.1, secondary grinding 8.3, flotation 7.5, concentrate handling 1.9, tailings disposal 2.2, assaying and sampling 1.4, mill H_2O 5.9, mill dept. 5.1, total 49.3.
A. H. E.

A plant for treating sulfide ores of lead. R. AVERAN. *Science ind.* **14**, 201, 779–82 (1930).—A description of the equipment and operation of a plant at Trémuson, France, for recovering Pb and Ag from local galena ores. Two [illegible]ry roastings reduce the

S content to 1.5–2%. The crude lead is melted; the Cu is removed at 400°; the As and Sb are removed by forced air at 900°. The Pb is remelted under an oxidizing atm. to form litharge, from which crude Ag is recovered. ANN NICHOLSON HIRD

Volatilization processes for low-grade zinc material. KURT R. GOEHRE. *Eng. Mining J.* 131, 19–20(1931).—The 4 prevailing volatilization processes are briefly discussed. The Waelz process is quite widely used, while the other com. process, the Laist process, is confined to slag and ores of low m. p. At present the main bulk of the production of the Waelz, Laist and Coley processes must be converted into metallic Zn. The oxide produced by the volatilization process cannot be treated in the old Belgian muffle furnace without sintering, because of excessive dust loss. At the New Jersey Zinc Co. the oxide is treated in a vertical muffle. The oxide is mixed with coal dust having a certain % of volatile matter and coked in a sep. furnace. With this procedure, no dusting results, and reduction takes place without disintegration, at a lower temp., and with a higher yield than was formerly possible. W. H. B

Oxygen as an aid in the solution of silver by cyanide from various silver minerals. E. S. LEAVER, J. A. WOOLF AND N. K. KARCHMER. Bur. Mines, *Rept. of Investigations* 3064, 15 pp.(1931).—Cerargyrite is completely sol. in cold cyanide soln. in 8 hrs. Practically all the Ag in stetefeldtite is dissolved by cold cyanide in 24 hrs. Argentite, polybasite, stephanite and pyrargyrite are slowly sol. under the usual conditions of cyanidation. Their rate of soln. is materially increased by supplying addnl. O. Proustite, similar in compn., did not show any material increase in extn. by use of O. By a preliminary low-temp. roast, an extreme case of oxidation, the resulting calcines yield an extn. of 90% of the Ag by cyanidation. Tetrahedrite is the most refractory mineral tested. Direct cyanidation, even with excess O, gave < 25% extn. Preliminary roasting increased this figure. In general, O is an aid in the treatment of Ag minerals by cyanidation. Warm soln. also increases the soln. rate. Low-temp. roasting is usually effective if the preceding fail. Usually 72 hrs. or more are required for max. soln. of Ag by cyanidation. ALDEN H. EMERY

Manufacture of portland cement and cupriferous iron from slag. J. A. BRADBURY *Chem. Eng. Mining Rev.* 22, 443–9; 23, 27–9(1930).—Research was conducted on the elec.-arc furnace smelting of Mt. Lyell blast-furnace slag with limestones and coke in proportions to produce: (*a*) slag, which on grinding would have the compn., properties and tensile strength of portland cement, and (*b*) cupriferous iron, which might be subsequently converted to mild steel, or used as an addn. to produce steel of high resistance to corrosion. Preliminary expts. indicated disadvantages of the process but established that (1) it is necessary to design a furnace to minimize chilling of the slag pool, and to eliminate air vents which would waste coke and electrodes; (2) careful choice of basic refractories is necessary to minimize slag contamination, and to afford max. of heat resistivity in a small intermittent arc furnace; (3) considerable difficulty in proportioning the constituent of the charge is expected because of the use of four main stocks, blast furnace slag, limestone, coke and small proportions of clay; (4) it is doubtful whether the high temp. of the elec. arc would permit the functioning of normal C reduction; (5) literature on cement manuf. discourages fusion of the clinker as being productive of inferior cement. Points studied include: hearth refractories, charge proportioning, FeO reduction, reduction of MgO, slag behavior, properties of cement produced, cement grinding, iron produced and the effects of small percentages of Cu in steel. The cupriferous iron obtained in the specially designed furnace analyzed: Fe 88.8, Cu 0.95, Mg 1.1%, Ca nil, As, Sb, Co, Ni, Zn, Pb nil to faint trace, Si 5.6, C 3.05, P 0.5, S 0.04%. Elec.-furnace iron evidently differs from normal cast iron in the higher percentages of easily removable impurities, such as Si and C, in the unusual presence of Mg, and in the presence of a small proportion of Cu which would not readily yield to refining methods. Opinions of numerous investigators on the effects of Cu on corrosion-resistance of iron are briefly reviewed. W. H. BOYNTON

Carbon is controlled in synthetic gray iron. EDWIN BREMER. *Foundry* 58, No. 22, 51–2(1930).—Synthetic gray iron is produced from 3 to 4% Si steel by adding to the charge in a Detroit Electric furnace sufficient petroleum coke to give the required C content. In tests carried out with high-Si steel as the base metal, a charge of 1 ton melted in 1 hr. and 40 min. The following figures are, resp., the percent coke added and the percent C content of the iron: 3.95, 3.05; 4.70, 3.30; 4.70, 3.35; 4.85, 3.35; 5.20, 3.40; 5.25, 3.46; 5.25, 3.43; 5.70, 3.60. The resulting iron may be varied between 2 and 3.50% Si and 2.5 and 3.5% C. G. T. MOTOK

Calculation of the temperature of combustion of a few metals. ILJA WEISTERMANN. *Metall u. Erz* 27, 613–5(1930).—The temps. of combustion for various metals are detd. by plotting the heat content of the metal in question as a function of temp.

A line is drawn from the ordinate corresponding to the heat of combustion of the metal, and the abscissa corresponding to the point where this intersects the heat-content curve represents the combustion temp. of the metal. The following results were obtained: for Pb —1470°, Sn —1950°, Zn —1800°, Cd —1385°, Bi —1890°. By extrapolation above the m. p., comparative temps. are detd. which would result if no vaporization or dissocn. occurred. These are designated T_s and are for Pb heated in O at 0 —4150°, for Zn in O at 0 —6400°, for Cd in O at 0 —5000°, and for Bi, Sb and Cu under the same conditions, 3800°, 5300° and 2200°, resp. H. STOERTZ

The new foundry of the Skoda works at Pilsen. JOH. MEHRTENS. *Z. Metallkunde* **22**, 304–7(1930). ROBERT F. MEHL

Metal stocks and intermediate products in lead foundry operation and the possibility of their limitation. BERGRAT GEORGE. *Metall u. Erz* **27**, 605–12(1930).—A discussion of the source and significance of metal stocks, with consideration of conditions which will bring about a decrease in the decline of intermediate products. H. S.

Cupola practice in the malleable iron foundry. J. H. D. BRADSHAW. *Foundry Trade J.* **43**, 361–2(1930).—Although more reliable malleable Fe castings may be obtained from crucible or pot melting, the cupola is gradually displacing crucible melting because of its cheapness. Its principal disadvantage is that the compn. of the product cannot always be guaranteed, but with careful control it will yield castings equal to, and sometimes superior to, crucible-melted ones, and at a lower cost. Regularity depends upon the correct vol. of air, an adequate blast pressure, and the correct charge calcn. The disposition of C, Si, Mn, S and P during melting is discussed, as are also the cost of coke used, the casting temp., and the slag formed. CURTIS L. WILSON

The constant-air-weight method of cupola blowing. H. V. CRAWFORD. *Gen. Elec. Rev.* **33**, 626–33(1930).—In the past, air for cupola blowing has been supplied at a certain pressure and a const. vol. The more logical method of supplying air by the const.-weight cupola blower with automatic control is described. The weight of air required will depend upon the C in the coke, moisture in the coke, density and size of coke, the loss by leakage, the humidity, the ratio of Fe to coke charges and atm. temp. and pressure. Various other factors governing operating conditions are discussed along with the effects of excess or insufficient O_2. A. D. SPILLMAN

Blast furnace theory and practice. RALPH H. SWEETSER. *Blast Furnace & Steel Plant* **18**, 1824–6, 1828(1930); cf. *C. A.* **24**, 574.—A survey of the progress and operation during recent years. A part of the progress has been due to improvements in app. tending to more uniform operation, and to a few changes in the dimensions of the interior of the blast furnace. "The greatest advances have been due to causes other than mech. and have been brought about more by changes in our attitude of mind than by changes in design and equipment." The capacity of a blast furnace must be expressed in terms of lbs. of coke which can be burned per day. To cover variations in operation, it is necessary to adopt a base coke, a base theoretical-yield ore mixt. and a base hot blast temp., and then make allowances for variations as encountered. Blast-furnace gas is now used for underfiring by-product coke ovens in the U. S., though used in Germany for several yrs. The 3-shift day has resulted in a greater output per man, a much higher rate of wages per hr., reduction in labor turnover, practically the same labor cost per ton of pig iron and practically the same monthly earnings at 8 hrs. per day as were formerly obtained at 12 hrs. per day. W. H. BOYNTON

Hot-blast furnace problems. WM. MCCONNACHIE. *Blast Furnace & Steel Plant* **18**, 1827–8(1930); cf. *C. A.* **24**, 5972.—In an attempt to show what removes O_2 from the ore, a close study was made of conditions obtaining in blast furnaces, the fuel used being the bituminous coal in general use in Scotland. It appears that there is no intrinsic difference in the conditions of a coal furnace about and below tuyère level from those of a coke furnace, so that the reasons for the remarkable differences in fuel requirement must be looked for higher in the furnace. Probably the heavier tarry matters expelled from the coal are intercepted and condensed on the cold material of the charges and so are taken down to lower and hotter levels, are again distd. off and again intercepted. From the wt. of O_2 contributed to the gases by the Fe_2O_3, SiO_2, CaO, etc., which is re-

duced, it is possible to calc. the O_2, etc., brought in by the blast and thereby get at the total amount of oxidized C present in the gases. The part played by tars in carburizing the Fe and in removing O_2 from Fe_2O_3 and Fe_3O_4 in the partially reduced ores is indicated. W. H. BOYNTON

Fuel impregnation by the slag in the hearth and bosh of the blast furnace. C. D. ABELL. *Foundry Trade J.* **43**, 410(1930).—Analyses of 3 main types of impregnations found in the coke of the cold-blast furnace are given. The "amber slag" is considered to be a definite phys. and chem. entity. The "mineralized fuel," found in the central zone of the furnace hearth, is a silicified C and contains much free Fe and graphite, as well as metallic carbides. The "white slag" is obtained by the burning away of the mineralized fuel. CURTIS L. WILSON

Electromagnetic apparatus for locating ore deposits, etc. AKTIEBOLAGET ELEKTRISK MALMLETNING. Ger. 512,054, Feb. 9, 1926. This corresponds to Brit. 251,429.

Apparatus for grinding ores. HARDINGE CO., INC. Fr. 689,042, Jan. 28, 1930.

Enriching ores. AUGUSTE DE CASEMBROOT. Fr. 691,184, May 15, 1929. Zn and other ores contg. limestone are enriched by calcining to about 700° and putting them immediately into water, where they are freed from CaO.

Enriching ores. EUGÈNE C. SAINT-JACQUES and SOC. NOUVELLE DE METALLISATION. Fr. 691,176, May 15, 1929. Ores are enriched by calibrating them to present to the grinders pieces of the same size. The subsequent grinding will break the softer pieces, which are sepd. by screening.

Centrifugal apparatus for enriching ores, etc. HANS KAMMERL. Fr. 690,321, Feb. 20, 1930.

Slaking apparatus for the dry treatment of ores. MASCHINENBAU-ANSTALT HUMBOLDT. Fr. 688,768, Jan. 23, 1930.

Treating ores or metals. SINDICATO MAQUEPA. Fr. 690,608, May 3, 1929. Ores or metals are mixed with a soln. of a halogen salt, *e. g.*, NaCl, and a nitrate, *e. g.*, $NaNO_3$; the mixt. is treated with decomposing acid such as H_2SO_4, whereby a nascent nitrosyl gas such as ClON is produced, which acts on the metals or ores to form salts. The mass may be stirred and heated by warm compressed air, and if it is desired to increase the intensity of the reaction an oxidizing substance such as MnO_2 may be added to the soln.

Reduction of ores. ALFRED MUSSO. Fr. 690,255, Dec. 23, 1929. Ores, particularly fine ores, are reduced at a relatively low temp. in a retort by the fixed C of a carbonaceous material and the forced and simultaneous evacuation of the gas products. The temp. used is below the m. p. of the metal or the gang and increases from the point of entry to the point of exit of the retort. The gases obtained have a high combustion value.

Reducing ores. HERBERT WITTEK. U. S. 1,787,348, Dec. 30. Ore such as roasted Zn blende ore or cinnabar is mixed with carbide such as CaC_2; the carbide in the mixt. is then "azotized" (suitably by N at 1000–1100°) to reduce metal values and to produce "nitro-lime."

Reducing ores such as those of iron. E. A. A. GRÖNWALL and H. J. H. NATHORST. Brit. 334,700, April 26, 1929. In effecting reduction in a shaft furnace with carbonaceous reducing agents, the combustible gases escaping at the upper portion of the furnace are partly burnt with O and blown back into the charge, and a continual circulation is maintained. In a modified procedure, the escaping gases are treated for removal of CO_2, then partly burnt with O, passed through C to increase their CO content and again partly burnt with O before being blown back into the charge. The O used may be obtained by the Linde process or by electrolysis of water (in which latter case the H formed is blown into the furnace). Various details of app. and procedure are described.

Reduction of metallic halides. I. G. FARBENIND. A.-G. Fr. 690,141, Feb. 18, 1930. Metal halides are reduced by H in vessels composed wholly or in part of metals, preferably of the same metal as it is desired to obtain; if another metal is used the product is only partly removed from the walls of the vessel.

Briquetting chromium-iron ore concentrates. M. N. TKACHENKO. Russ. 68,090, April 30, 1930. The wet ore is mixed with up to 5% of $Mg(OH)_2$ and then pressed into briquets.

Treating copper ores. M. MIYAKE. Brit. 334,761, Oct. 18, 1929. With the purpose of reducing the quantity of SO_2 evolved in roasting copper glance, the material is mixed with bone ash and "red earth."

Treating iron pyrites. STANLEY I. LEVY and GEORGE W. GRAY. Ger. 510,139, March 28, 1928. See Brit. 307,188 (*C. A.* **23**, 5150).

Treating titanium ores. TITAN CO. A.-S. (P. Farup, inventor). Ger. 510,200, May 4, 1928. See Brit. 275,580 (*C. A.* **22**, 2247).

Vanadium ores. SOC. DE PRODUITS CHIM. DES TERRES RARES (SOC. ANON.). Fr. 36,572 (Addn. to 669,115, March 13, 1929. Addn. to 669,115 (*C. A.* **24**, 1611). In treating V ores by the process of Fr. 669,115, Fe in the form of $FeSO_4$ is added to the solns. from which it is desired to recover vanadic acid, if the ores are free from, or insufficient in, Fe to obtain this result. This addn. may be made before or after the first hydrolysis of vanadic acid.

Sintering pulverulent ores, etc. VEREINIGTE STAHLWERKE A.-G. (Albert Daub, inventor). Ger. 512,171, Nov. 10, 1929. The ore, etc., is packed in a shaft having a stationary lower part and an upper part adapted to be lifted off. Hot gases are passed downwardly through the ore, and the operation is continued until the sintering zone has reached the junction of the two parts of the shaft.

Roasting ores. METALLGES. A.-G. Fr. 688,928, Jan. 27, 1930. See Ger. 502,586 (*C. A.* **25**, 479).

Apparatus for roasting and agglomerating ores. ADRIEN DAWANS. Fr. 689,324, Feb. 3, 1930.

Metallurgical furnaces. ALFRED STANSFIELD. Fr. 689,345, Feb. 3, 1930.

Prolonging the life of blast-furnace shafts by air cooling. SOC. ANON. JOHN COCKERILL. Fr. 691,221, Mar. 5, 1930. See Belg. 366,775 (*C. A.* **24**, 4754).

Blast-furnace processes. ERNST BAUMGARTNER. Fr. 689,678, Feb. 10, 1930. Basic fluxes (limestone or dolomite) for use in blast-furnace processes are calcined for the removal of CO_2 only to such a degree that the calcined product retains its size and the necessary resistance to maintain the charge and to allow the furnace to function properly.

Charging device for blast furnaces. AWANS-FRANÇOIS SOC. ANON. Ger. 510,820, May 25, 1929.

Die-casting machines. PRÄZISIONSGUSS-FABRIK NÜRNBERG GEBR. ECKERT. Ger. 510,366, Jan. 23, 1929. Details of the arrangement of the melting pot are described.

Centrifugal casting apparatus. SOCIETÀ ALTI FORNI, FONDERIE, ACCIAIERIE E FERRIERE FRANCHI-GEGORINI. Ger. 512,062, June 7, 1928.

Method of casting hollow metal bodies. MARTIN ROECKNER and CARL DAEVES. Ger. 510,497, June 7, 1929.

Casting hollow articles of aluminum alloy. METAL CASTINGS, LTD., and A. H. NICHOLSON. Brit. 334,714, Sept. 12, 1929. Cores for use in the casting are made of a

Zn alloy or other suitable metal, which will not melt during casting but can be removed after casting by a heat treatment.

Casting aluminum and its alloys. VEREINIGTE ALUMINIUM-WERKE A.-G. Brit. 334,435, Oct. 29, 1928. Mech. features.

Casting of aluminum alloy. EUGEN STRASSER (to Max Dietiker). U. S. 1,788,751, Jan. 13. A preliminary alloy contg. Cu 90 and Ni 5 parts is covered with a fused layer of KF adapted to scorify the metal oxides present; about 5% of Mg is added while stirring and the preliminary alloy is cast. About 2% of this preliminary alloy is added to Al or Al-Zn alloy contg. up to 18% Zn and the metal is cast in a mold of material having a chilling effect on the alloy (the mold contg. granulated metal and having a water content of about 6%). Subsequent heat treatment for aging is not required, because of the aging effect which takes place during the process.

Casting steel. VEREINIGTE STAHLWERKE A.-G. Ger. 512,061, Feb. 14, 1930. This relates to the manuf. of compound steel castings in a mold having a removable partition, which is removed when one of the steels has been cast. The improvement consists in treating the first steel, directly after removing the partition, with a current of air or steam, so as to form a superficial layer of Fe_3O_4. The second steel is then poured in.

Refining metals. WALTER C. SMITH (to Allied Process Corp.). Can. 307,857, Jan. 20, 1931. Molten metal is deoxidized with an agent of the group including P and Si, and thereafter the molten metal is treated with Li. Cu, Cu alloys such as brasses and bronzes, and other metals and alloys such as Zn and its alloys, Ni, Cu-Ni alloys, Fe, steel and ferrous alloys, as rustless Fe, may be treated in this way to produce sound ingots and castings.

Refining metals, ores, etc. M. I. GUTMAN and G. YA. Russ. 53,703, Nov. 21, 1929. Cl is admitted into the blast furnace and acts on the molten metal.

Refining copper. ELECTRICAL RESEARCH PRODUCTS, INC. Fr. 690,219 Feb. 19, 1930. Metallic Cu of high cond., which may be heated in a reducing atm. without breaking, is prepd. by maintaining pure molten Cu in a vessel having a covering of a refractory material such as Al_2O_3, which prevents traces of impurities such as Fe from entering the Cu, and adding a deoxidizing agent to the Cu. Ca_2B_2 may be added to the bath immediately before casting.

Refining nickel and copper. HENRI J. M. E. CLERC. Fr. 36,617, Mar. 30, 1929. Addn. to 633,109 (*C. A.* **24**, 1610). Ni, Cu or alloys of Ni and Cu are refined by chlorination with alkali alk. earth, or earth chlorides which act on the oxides by double decomp., and form with the impurities volatile chlorides. The chlorides are injected in the fused state by a gaseous current which may be Cl or air or both. Cf. *C. A.* **24**, 815.

Refining zinc residues. RAYMOND THOMAS and FRANZ SCHREIBER. Fr. 688,649, Dec. 19, 1929. In melting Zn, the formation of ZnO is prevented by introducing into the furnace at the commencement of the operation substances which vaporize, expel the air and form a reducing atm. Hydrocarbous or glycerol in emulsion with water with or without addn. of emulsifiers, HCl, $ZnCl_2$ and NH_4 salts may be used. The superheated steam formed causes the rupture and retraction of the layer of oxide on the surface of the Zn.

Zinc. THE NEW JERSEY ZINC CO. Fr. 690,027, Feb. 15, 1930. Zn vapor obtained in the reduction of Zn materials is purified by passing it through a medium for eliminating Pb kept at a suitable temp. The medium may be one of the ingredients of the reduction charge of Zn, or the reduction charge itself composed of the Zn material and a carbonaceous reducing agent.

Aluminum. JEAN HANCO. Fr. 689,593, Feb. 7, 1930. Pure Al is made by adding to the molten Al about 3% of a mixt. of equal parts of fused dry $CaCl_2$ and borax, both finely ground, which mixt. in the molten Al at 900° is liquefied and absorbs impurities. The mech. resistance of the Al may be increased without impairing its cond. by adding Ce or metals derived from Ce ores.

Finely divided metals. I. G. FARBENIND. A.-G. Fr. 691,243, Mar. 6, 1930. Finely divided metals are made by decompn. of their carbonyl compds. in a heated vacuum, a whirling motion being imparted to the carbonyl compds. Cf. *C. A.* **24**, 3748.

Pickling metals. P. J. COLE and C. BANTA (to Barrett Co.). Brit. 334,418, Oct. 31, 1928. Pickling baths such as H_2SO_4 or HCl are used with inhibitors such as benzo-, toluo- or naphthonitrile or α- or β-naphthonitrile in small proportion. Cf. *C. A.* **24**, 3482.

Nitriding. CENTRAL ALLOY STEEL CORP. Fr. 688,616, Jan. 21, 1930. The walls of nitriding vessels are covered with a substance inert to the NH_3 gas used, *e. g.*, enamel.

Cold brass rolling. JOHN C. SHARP (to Standard Oil Co. of Ind.). U. S. 1,789,054, Jan. 13. Before entering the cold rolls, soft metal such as brass is treated with a lubricating oil contg. an alkali metal compd. of petroleum sulfonic acids.

Temperature indicator for carburizing boxes. HENRY H. HARRIS (to General Alloys Co.). U. S. 1,788,794, Jan. 13. A metallic "tell-tale," such as a plug of brass, Ag or Ni alloy which is fusible at a predetd. temp., is embedded in the wall of a device such as a carburizing box to indicate any possible subjection of the box and contents to temps. above those intended.

Reheating metals. FAGERSTA BRUKS AKTIEBOLAG. Fr. 690,203, Feb. 19, 1930. Surface decarbonation in reheating metals, particularly steel, is avoided by heating them in a chamber into which is introduced a gas obtained by passing blast-furnace gases or gases of like compn. through a layer of incandescent C heated by elec. means.

Hardening metals and alloys. GUSTAV SCHOENBERG. Swiss 140,790, May 2, 1929. Metals and alloys which do not readily undergo cementation are improved by immersion in a molten bath contg. at least 10% of a substance capable of oxidation, such as salts of HCN, or powd. C. The bath may be a fused mixt. of salts, and KOH may be present. The method is particularly suitable for hardening Au, Ag, Ni, Cu and their alloys.

Hardening metals such as iron, steel, copper and their alloys. DAVID LAMON. U. S. 1,788,876, Jan. 13. The metal is heated to convert it into a "semi-molten" state, the surface of the heated metal is sprinkled or covered with a mixt. which may be formed of KCN 2, H_3BO_3 1 and molybdic acid 1 part. Molybdic acid anhydride also may be used.

Hardening of iron and steel. KHIMICHESKII INSTITUT IM. L. YA. KARPOVA. NTU. VSNKh. SSSR. (Chemical Institute Karpov Memorial). Russ. 49,418, June 17, 1929. The object to be hardened is introduced into a bath prepd. by fusing KF or NaF or their mixts.; then there is added a mixt. of clay and $K_3Fe(CN)_6$ compressed into small agglomerates.

Fused bath for case-hardening metals. PORTER W. SHIMER and EDWARD B. SHIMER (to American Cyanamid Co.). U. S. 1,789,257, Jan. 13. The case-hardening properties of a fused bath such as $CaCl_2$, NaCl and a cyanamide are maintained by regular frequent addns. of a cyanide-forming material such as Ca cyanamide. U. S. 1,789,258 relates to a molten case-hardening bath which may be formed of a Ca halide such as $CaCl_2$, an alkali metal halide such as NaCl and a minor proportion of alk. earth metal cyanide such as $Ca(CN)_2$. U. S. 1,789,259 specifies making frequent regular addns. of an alk. earth metal cyanide such as $Ca(CN)_2$ to maintain the case-hardening properties of a bath which may contain fused chlorides and a cyanamide.

Apparatus for the thermal treatment of steel rails. CHARLES W. ST. J. ROWLANDSON and CHARLES J. GRIST. Ger. 512,036, April 4, 1928. This corresponds to Brit. 288,369.

Apparatus for annealing wire, metal sheets, etc. AKT.-GES. BROWN, BOVERI & CIE. Swiss 140,789, May 1, 1929.

Pot-annealing oven for wires, bands, etc. ERNST BECKERT NADELFABRIK COM.-GES. Ger. 510,208, Jan. 26, 1927.

Annealing gray iron. ROYSEL J. COWAN (to Surface Combustion Co.). U. S. 1,789,136, Jan. 13. The iron is heated to a temp. above its crit. point, held at this temp. for a time sufficient to initiate graphitization, and, before the graphitization has stopped, is cooled by quenching in the open air.

Annealing steel. HEINRICH HANEMANN. Fr. 36,667, April 8, 1929. Addn. to 667,217. Steel objects are annealed by heating them with a direct elec. current in a vacuum.

Cementation of steel articles. A. N. NAZAROV. Russ. 44,445, April 6, 1929. Articles placed in an iron container and heated to the required temp. are treated alternately with CO and H_2.

Cast iron. YVES LE M. DE SAGAZAN and PHOSPHATES ET SUPERPHOSPHATES DE TEBBAKA. Fr. 689,895, April 19, 1929. P is introduced into cast iron in the form of Fe phosphide either in the blast furnace or in the Bessemer converter.

Cast iron. VEREINIGTE STAHLWERKE A.-G. and KARL EMMEL. Ger. 519,391, Dec. 10, 1924. See Brit. 244,405 (*C. A.* **21**, 220).

Alloy. HENRY A. BEHRENS. Can. 307,257, Jan. 6, 1931. A cryst. alloy readily cast to form electrodes comprises Sn, Cu, Pb, Bi and Sb.

Alloy. FRANK A. FAHRENWALD. Can. 307,527, Jan. 6, 1931. An austenitic Fe alloy contg. Cr 5–25, Mn 1.5–5, Ni 1.5–10, C 0.3–3 and Si 0.0–3% is used in tool making.

Alloys. HANS KANZ. Fr. 689,079, Jan. 29, 1930. An alloy suitable for parts submitted to friction contains, *e. g.*, Cu 58, Sn 4, Zn 34, Pb 2.5 and Ni 1.5%. Cf. *C. A.* **25**, 677.

Alloys. THE INTERNATIONAL NICKEL CO., INC. Fr. 688,967, Jan. 27, 1930.

Alloys suitable for use by dentists, etc., for conducting heat and electricity and which are resistant to corrosion contain Pd 25–98, Cu 1–60 and Ag the rest (not less than 1%). Heat treatments for improving the qualities of the alloys are described. Cf. *C. A.* 25, 677.

Aluminum alloys. H. C. HALL and T. F. BRADBURY. Brit. 334,430, Oct. 24, 1929. Al alloys are described contg. Mg 0.1–4.0, Ni 0.5–2.5, Fe 0.3–1.5, Si 0.5–5.0, Ti up to 0.5, Mn up to 0.2, Cr 0.01–0.2 and Cu up to 0.5%. Na may be used as a refining agent in prepg. the alloys.

Aluminum alloys. K. SCHMIDT GES. Brit. 334,777, Aug. 15, 1929. Alloys suitable for manuf. of pistons for internal-combustion engines contain Al over 70%, together with Si 15–25, Cr 0.2–3.0 and Mn, Co and Ni 0.5–3.0% each, with or without Ti or Mo 0.5–1.0%. Sb 0.5–3.0% and some Fe also may be present. Cf. *C. A.* 25, 678.

Aluminum alloys. AKT.-GES. DER EISEN- UND STAHLWERKE VORMALS GEORG FISCHER & MESSINGWERK SCHWARZWALD A.-G. Fr. 689,206, Jan. 31, 1930. Al alloys, for the foundry, contg intermetallic combinations of alkali and alk. earth metals and one metal at least of each of groups 1, 6, 7 and 8 are prepd. by adding intermediate alloys in the usual manner to the fused Al bath, after which an alkali and an alk earth metal as metal or intermediate alloy is added to the bath, on which an autorefining takes place by aging, *i. e.*, by leaving the alloy to stand.

Aluminum alloys suitable for pistons. R. S. ARCHER and L. W. KEMPF (to Aluminium, Ltd.). Brit. 334,656, Dec. 22, 1928. Al is alloyed with Si 7–15, Mg 0.2–1.5, Ni 0.5–7.0 and Cu 0.7–3.0%, and in some cases Mn, Cr and Ti may also be added. Fe may be present as an impurity. Some mention is also made of alloys contg. a greater proportion of Si. Cf. *C. A.* 24, 4254.

Hard aluminum alloy. E. I. PETROV. Russ. 56,640, Oct. 18, 1929. An alloy contg. 90% Al and 5% Cu is prepd. by adding Cu to Al. A mixt. amounting to 5% of K_2MnO_4, Na_2CO_3, NaCl and aniline is then added to the molten alloy.

Copper alloys. WILHELM KROLL and M. LISSAUER ET CIE. Fr. 690,503, Feb. 24, 1930. Cu contg Ti or alloys of Cu contg. Ti are improved by quickly cooling the metal from a temp. of 650–1000° or allowing it to cool in the air and then aging it at 200–400°.

Iron and titanium alloy. WILHELM KROLL. Fr. 689,556, Feb. 7, 1930. Alloys of Fe and Ti are improved by submitting them to a chilling or cooling in air from a temp. of 700–1550° and aging them artificially to increase their hardness by reheating to 200–500°.

Alloys of magnesium. I. G. FARBENIND. A.-G. Fr. 36,601, Mar. 15, 1929. Addn. to 668,868 (*C. A.* 24, 1613). Alloys of Mg which are wetted momentarily by water, e. g., tools, are protected against corrosion by adding to the water a small quantity (about 1%) of dichromate.

Light magnesium alloy containing also aluminum, copper and manganese. EDWARD BURDICK (to Dow Chemical Co.). U. S. 1,788,616, Jan. 13. An alloy contains Mg 93, Al 6, Cu 0.7 and Mn about 0.25%.

Zinc-base alloys. WILLIS M. PEIRCE and EDMUND A. ANDERSON (to The New Jersey Zinc Co.). Can. 307,926-29-30-31-32, Jan. 20, 1931. Zn alloys that can be mechanically worked to produce wrought products possessing superior resistance to cold flow contain (a) 0.05–2% Cu and 0.005–0.5% Mg; (b) about 1% Cu and about 0.3 to 0.5% Mn; (c) about 1% Cu and about 0.05% Li; (d) about 1% Cu and about 0.1 to 0.5% Ni; (e) about 0.5% Cd and about 0.05% Li.

Determination of the resistance to rusting of iron alloys. VEREINIGTE STAHLWERKE A.-G. Fr. 689,093, Jan. 29, 1930. The resistance to rusting of Fe alloys is rapidly by detg. the resistance of the metal to vibrations first in the ordinary manner and afterward while submitting it to the action of water or moist air.

Acetylides. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Fr. 689,160, Feb. 5, 1930. Acetylides of alkali metals or their alloys are made by treating molten metals with C_2H_2 on constantly renewed fresh surfaces of the metal, *e. g.*, in a rotating drum or tube.

Coating ferrous metals with zinc and aluminum alloy. EARL R. WEHR and CARL C. MARCH (to American Rolling Mill Co.). U. S. 1,788,755, Jan. 13. In making products with a permanent rough-textured surface, ferrous metal bodies such as sheets, plates or strips are treated with an alloy which may contain Zn 97% or less and Al 3% (or more) in molten condition; the body and coating are subsequently heated to approx. the m. p. of the coating or above so as to effect a suitable crystn.

Apparatus suitable for use in coating metal sheets with zinc or its alloys. BENJAMIN P. FINKBONE (to American Rolling Mill Co.). U. S. 1,789,172, Jan. 13. A pot

suitable for holding molten Zn, etc., is provided at its exit end with an internal shell of an alloy of Ni, Cr and Fe contg. at least 10% of Cr to avoid solvent action with the coating material; a partition is placed between the exit portion and the remaining portion of the pot.

Coating non-metallic surfaces with nickel and other metals. J. G. A. RHODIN and BRITISH METALLISING CO., LTD. Brit. 334,510, May 29, 1929. Articles such as SiC elec. resistance rods for heating or abrasive wheels are coated with Ni by heating to above 350° and immersing in a soln. of Ni tetracarbonyl in C_2HCl_3, $C_2H_2Cl_4$, $CHCl_3$, Cl-substituted polybasic alcs., glycolchlorohydrin, epichlorohydrin or other suitable non-inflammable solvent. The coating may be rendered more firmly adherent by heating the coated article to redness after its removal from the soln. Over the coating thus produced, there may be applied an electroplated coating of addnl. Ni or coatings of other metals such as Cr, Ag, Cu, Au or Al, applied by various methods (details of some of which are given).

Metallizing non-metallic cores of bobbins for use on looms, etc. BRITISH CELANESE, LTD., W. A. DICKIE and F. C. HALE. Brit. 334,174, May 21, 1929. Cores such as those of wood, fiber, cardboard and paper are coated by the application of fused metal under high velocity, such as may be produced by fusing a metal wire or ribbon in an O-H or O-coal gas flame; the fused metal is projected onto the core by a strong air current.

Coloring metals. ALADAR PACZ. Ger. 510,380, Oct. 30, 1927. Metals are colored by cathodic treatment in a neutral or acid bath of NH_4 molybdate to which other NH_4 salts (other than sulfomolybdates) have been added, a sol. anode being employed, *e. g.*, Zn. When the cathode is more electropos. than the anode, no external source of current need be used, the anode and the cathode being directly connected. A suitable bath contains NH_4 molybdate 0.125 and NH_4NO_3 0.5%.

Blow-pipe apparatus for cutting metals by fusion. M. CLAUDE. Brit. 334,162, March 5, 1929. Structural features.

Magnetic testing apparatus for determining the physical properties of materials such as steel cutting tools. JAMES A. SAMS and VIRGIL F. SHAW (to General Elec Co.). U. S. 1,789,196, Jan. 13. Structural and elec. features.

Renovating files and like cutting tools with multiple edges. M. M. TURNER Brit. 334,517, April 3, 1929. The tools are immersed in successive acid baths, the cutting edges being protected (as by a Barbadoes tar soln. or the like) during some of the immersions and exposed to the acid during at least one of the later immersions. Use of HNO_3 and H_2SO_4 after a preliminary boiling in KOH soln. and then in $Ca(OH)_2$ soln. is described.

Aluminothermic welding. ELEKTRO-THERMIT G. M. B. H. Fr. 689,248, Feb. 1, 1930. The Fe scrap which is added to the aluminothermic mixt. is previously mixed with ferromanganese or ferrosilicon.

Welding copper. FRIED. KRUPP A.-G. Fr. 689,636, Feb. 8, 1930. Welding for Cu is carried out with electrodes made of carbides of W or like metals of high fusion pt., *e. g.*, "Widia", with a small quantity of metals of lower m. p.

Solder. ALLGEMEINE ELEKTRIZITÄTS-GES. Fr. 689,008, Jan. 28, 1930. A solder for Fe or steel is composed of an alloy of Cu and Ni, to which a more easily fusible metal such as Zn, Sn, Pb, Al or Cd may be added.

Soldering. I. G. FARBENIND. A.-G. Fr. 691,242, Mar. 6, 1930. Metals for soldering are made by decompn. of their carbonyl compds.

Soldering metals. LA SOUDURE AUTOGÈNE FRANÇAISE. Fr. 688,915, April 17, 1929. In soldering easily oxidizable metals by blowpipe, the flame is surrounded by a gaseous sheath of hydrogen.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Oxidation of "triisobutylene" by ozone. ROBERT J. MCCUBBIN. *J. Am. Chem. Soc.* 53, 356–9(1931); cf. M. and Adkins, *C. A.* 24, 3483.—"Triisobutylene," b$_{14}$ 175.5–9°, with O_3 in AcOH contg. 1.5–2% Ac_2O, gives as oxidation products an av. yield of 0.38 mol. Me_3CCHO, 0.40 mol. Me_3CCH_2Ac, 0.18 mol. $(Me_3CCH_2)_2CO$ and 0.16 mol. $(Me_3C)_2CMeAc$. These results indicate that triisobutylene exists in at least 3 isomeric forms, present in an approx. ratio of 2 mols. of $Me_3CCH_2CMe{:}CHCMe_3$ and 1 mol. each of $Me_3CC(CMe_3){:}CMe_2$ (I) and $Me_3CCH_2C(:CH_2)CH_2CMe_3$. It also seems apparent that during hydrolysis of the ozonide the hydrocarbon of formula I

undergoes a pinacolone rearrangement instead of breaking down into 2 simple ketones. C. J. WEST

Synthesis and pyrolysis of methylallene and ethylacetylene. CHARLES D. HURD AND RICHARD N. MEINERT. *J. Am. Chem. Soc.* **53**, 289–300(1931).—MeCHBrCHBr-CH_2Br b_{14} 100–1°, n^{20} 1.5680; NaOH gives 86% of *MeCHBrCBr:CH*$_2$, b_{20} 75°, $n^{2}_{D}{}^{8}$ 1.5556, n^{20}_{D} 1.5464, $n^{26}_{D}{}^{5}$ 1.5430, dn/dT = —0.00053; Br in CCl_4 gives $MeCHBrCBr_2$-CH_2Br, m. —2°, b_7 97.5°, d^{20}_4 2.510, $n^{3.6}$ 1.6152, n^{20} 1.6070; Zn dust in EtOH gives 72% of $MeCH:C:CH_2$, b. 10.3°, d^{0}_4 0.676, $n^{1}_{D}{}^{3}$ 1.4205. This polymerizes when pyrolyzed, the *compd.* C_8H_{12}, b. 110–5°, n^{27} 1.4758, being isolated; in addn. to the polymers CH_4, C_2H_6, C_2H_4, H, C_3H_8 and allene are formed in small amts. EtC : CH has been prepd. from CH : CNa and Et_2SO_4 in 60% yields. In its pyrolysis from 33 to 50% of the material is converted into liquids which resemble the liquids formed from $MeCH:C:CH_2$, $CH_2:C:CH_2$ and MeC : CH. In addn. to the liquids there were produced paraffin hydrocarbons, H, C_2H_4 and C_3H_6 in the ratio approx. of 9.3:2.2, as well as small quantities of C_4H_6, MeC : CH and $CH_2:C:CH_2$. C. J. WEST

Thermal chlorination of methane by a flow method. ROBERT N. PEASE AND GEO. F. WALZ. *J. Am. Chem. Soc.* **53**, 382(1931).—The thermal (non-catalytic) chlorination of CH_4 by the flow method takes place readily in Pyrex glass above 200° at 1 atm. total pressure; the reaction is homogeneous and is bimol. At 225–300° the reaction is inhibited by O; at 375° 5% O has no measurable effect; this effect of O points to a chain mechanism. C. J. WEST

Photochemical reactions of gaseous methyl iodide. JOHN R. BATES AND ROBERT SPENCE. *J. Am. Chem. Soc.* **53**, 381(1931).—Studies of the photochem. decompn. and oxidation of gaseous MeI supports the idea that Me and I are the initial products (cf. *C. A.* **25**, 249); the reaction products are HCHO, $(CH_2O)_x$ and $CH_2(OMe)_2$, as well as free I. C. J. WEST

Alkyl peroxides. V. Barium methyl peroxide. ALFRED RIECHE AND FRITZ HITZ. *Ber.* **63B**, 2504–5(1930); cf. *C. A.* **24**, 1078.—$Ba(OH)_2$ is added to 30–50% aq. MeO_2H soln. in excess and the Ba salt pptd. by alc. The salt is too explosive to be entirely freed from alc. RCOCl give RCO_2OMe which are easily decompd. into MeO_2H and acid *p*-$C_6H_4(CO_2OMe)_2$, m. 125°, is stable. **VI. Monohydroxydialkyl peroxides.** ALFRED RIECHE. *Ibid* 2642–52(1930).—These are prepd. by allowing 5% Et_2O solns. of aldehyde and HO_2R to stand a day. The Et_2O is evapd. and the residue distd. *in vacuo*. Traces of H_2O cause explosions. $CH_2(OH)O_2Me$, b_{17} 45°, d^{15}_4 1.112, n^{15}_{D} 1.4083, reacts with alkali: $2\ MeO_2CH_2OH = 2.5\ HCO_2H + 1.5\ MeOH + 2\ H$. CH_2-$(OH)O_2Et$, b_{12} 46–8°, d^{16}_4 1.045, n^{16}_{D} 1.4043, is decompd. by alkali but according to no simple equation. With $Fe(SO_4)_2$ EtOH and HCO_2H result. $MeCH(OH)O_2Me$, b_{22} 29–31°, d^{15}_4 1.029, n^{15}_{D} 1.3930, decomps. with alkali in no simple way. $Fe(SO_4)_2$ also gives no simple reaction. $EtCH(OH)O_2Et$, b_{10} 50–52°, $d^{21.4}_4$ 0.974, $n^{21.4}_{D}$ 1.4021. Higher aldehydes yielded only mixts. V. F. HARRINGTON

Oxidation of sulfides with benzoyl peroxide. IV. L. N. LEVIN AND I. CHULKOV. *J. prakt. Chem.* **128**, 171–9(1930); cf. *C. A.* **24**, 4257.—$CH_2:CClSCH_2CH_2Cl$, b_4 92°, d^{20}_4 1.3123, n^{20} 1.5502, with Bz_2O_2 (1.85 g. active O for 18.2 g. sulfide) at —10° gives about 18 g. of *α-chlorovinyl β-chloroethyl sulfoxide*, b_4 104°, does not solidify at —20°, d^{20}_4 1.4048, n^{20} 1.5011; further oxidation gives the *sulfone* (also obtained from the sulfide and a larger amt. of Bz_2O_2), $b_{2-3.5}$ 108–9° (slight decompn.), d^{20}_4 1.4366, n^{20} 1.5238. Similarly, $ClCH:CHSCH_2CH_2Cl$, b_4 99°, d^{20}_4 1.3103, n^{20} 1.5490, with Bz_2O_2 gives a small amt. of $OS(CH_2CH_2Cl)_2$ and *β-chlorovinyl β-chloroethyl sulfoxide*, d^{20}_4 1.3924, n^{20} 1.5416, decomps. at 80° and 4 mm.; the sulfone, b_2 125–7°, d^{20}_4 1.4384, n^{20} 1.5306; a by-product is a compd. m. 109–11°, which was not identified. The results of 21 oxidations of the sulfides, sulfoxides and sulfones are given in a table. C. J. WEST

Reaction between certain organic sulfur compounds and sodium in liquid ammonia. F. F. WILLIAMS AND E. GEBAUER-FUELNEGG. *J. Am. Chem. Soc.* **53**, 352–6(1931).—Aliphatic sulfides react with Na in liquid NH_3 chiefly according to the equation: $R_2S + 2\ Na + NH_3 = RSNa + NaNH_2 + RH$. Under the same conditions, aliphatic disulfides are reduced quant. to the corresponding mercaptides: $R_2S_2 + 2\ Na = 2\ RSNa$. Aliphatic mercaptans react as follows: $RSH + NH_3 = RSNH_4$; $RSNH_4 + Na = RSNa + NH_3 + 0.5H_2$. No Na_2S is produced in any of these reactions; the reaction stops with the formation of mercaptide. C. J. WEST

Pentachloromethyl ether. IGNACY RABCEWICZ-ZUBKOWSKI AND STEFAN CHVA-

LIŃSKI. *Roczniki Chem.* **10**, 686–9(689 English)(1930).—By chlorination of $(CH_2Cl)_2O$, under the influence of ultra-violet light, *pentachloromethyl ether*, CCl_3OCHCl_2, is formed, b_{760} 158.5–9.5°, b_{30} 69–70°; a colorless liquid of a specific odor, insol. in H_2O, sol. in org. solvents, $d^{17.3}$ 1.6496, n_α 1.4772, n_β 1.4825, n_β 1.4879. When heated with water it decomps. slowly, giving CO, CO_2, HCl, CCl_4 and other products. With aq. $PhNH_2$ $CO(NHPh)_2$ is formed. J. KUČERA

Preparation of nitromethane. PETER P. PRITZL AND HOMER ADKINS. *J. Am. Chem. Soc.* **53**, 234–7(1931).—In the reaction of $ClCH_2CO_2Na$ and $NaNO_2$, mol. quantities being used, approx. 50% of the $NaNO_2$ is converted into $MeNO_2$, while about 24% gives $MeNO_2$ which undergoes further condensation to what is presumably the Na salt of methazonic acid. About 26% of the $NaNO_2$ does not react, chiefly because 15% or more of the $ClCH_2CO_2Na$ undergoes hydrolysis to Na glycolate. The formation of $MeNO_2$ may be increased to approx. 75% of the theory if a sufficient excess of $ClCH_2CO_2Na$ is used to insure the complete reaction of the $NaNO_2$. The actual yields of $MeNO_2$ obtained were about 9% lower than those given above, because of mech. losses on the scale of operation used in obtaining them. The wt. of $MeNO_2$ actually obtained may be increased by about 10% by modifying the standard method so that the $ClCH_2CO_2Na$ is introduced into the $NaNO_2$ soln. after the latter has been heated to the temp. of the reaction. A method is described for the *detn. of* $NaNO_2$ in the presence of NO_2 and methazonic acid and its condensation products C. J. WEST

Silica gel as a catalyst in the preparation of nitriles. JAMES A. MITCHELL AND E. EMMET REID. *J. Am. Chem. Soc.* **53**, 321–30(1931).—Silica gel is a more efficient catalyst than either thoria or alumina in the prepn. of nitriles from acids and NH. The optimum operating temp. for the reaction is 500°; at higher temps. the catalyst becomes foul; at these higher temps. $(NH_4)_2CO_3$ is formed. With AcOH, when the time of contact is 25 sec. at 500°, the % conversion is 95%; the yield is only 60% when the rate of flow is twice as fast. Highly purified gel and com. gel are of the same order of activity. The life of the catalyst is long with the acids and short with the esters studied. From the acids the following yields were obtained: MeCN 95%; EtCN 85%; PrCN 90%; BuCN 80%; iso-BuCN 94%; $C_6H_{11}CN$ 90%; $C_8H_{13}CN$ 93%; $C_{11}H_{21}CN$ 55%; $PhCH_2CN$ 87%; $PhCH_2CH_2CN$ 81%; no cyanide was obtained from palmitic acid. From the esters the following yields were obtained: MeCN 87%; PrCN 75%; PhCN 77%. The catalyst is only active in dehydrating amides and is not effective in the establishment of the NH_3-acid amide-H_2O equil. C. J. WEST

Organic tin compounds. J. G. F. DRUCE. *Chemist and Druggist* **112**, 643(1930); cf. *C. A.* **23**, 1870, 4670.—A review is given of the inter-relation of stannane, stannonic acid and the various halogen derivs. of stannane (stanniform, etc.), analogous to $CHCl_3$, etc The prepn. of the chief compds. is briefly described. S. WALDBOTT

Decomposition of ketones in the presence of silica gel. JAMES A. MITCHELL AND E. EMMET REID. *J. Am. Chem. Soc.* **53**, 330–7(1931).—The principal condensation product of Me_2CO in the presence of silica gel at 400–550° is 1,3,5-$C_6H_3Me_3$ (I); at 500° a 17% yield of I is obtained. This is the only catalyst that has effected this reaction at atm. pressure. The primary products in the homogeneous unimol. decompn. of Me_2CO are ketene and CH_4; the ketene then decomps. bimolecularly to C_2H_4 and CO. In the presence of silica gel at 460° the highest % of ketene produced was 4.4%, 65% of the Me_2CO being decompd. The gas evolved at this temp. contained 9% CO, 17% CH_4, 28% CO_2, 40% unsatd. hydrocarbons and 3% H. These facts show that the homogeneous decompn. of Me_2CO in the presence of silica gel is taking place to only a minor extent at the temp. employed. The presence of a small quantity of MeC:CH in the gaseous products would indicate that the mechanism of the formation of I is dehydration of the Me_2CO to MeC:CH and polymerization of the latter. Condensation products other than I are mesityl oxide, phorone, isophorone and xylitone. The gaseous fractions at 400°, 450°, 470° and 500° were also analyzed. An analogous reaction does not take place with MeEtCO to an appreciable extent, ketonic condensation products only are produced, homomesityl oxide, homophorone and homoisophorone being identified. A typical analysis of the gaseous products gave 15.5% CO_2, 12% CO, 15% unsatd. hydrocarbons, 2.2% H_2 and 30% CH_4. PhAc gives 1,3,5-$C_6H_3Ph_3$. C. J. WEST

Certain wax in rice polishings. UMR TANGE. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, 275–7(1930).—From rice polishings, melissyl cerotate was prepd. and identified. Extn. of rice polishings with 90% EtOH and subsequent cooling gave a ppt. of melissyl cerotate which was analyzed for C and H. Sapon. gave cerotic acid, isolated as the Ca salt, insol. in benzene, and melissyl alc., sol. in benzene. The Ca cerotate was hydrolyzed to cerotic acid which was recognized as such by analysis, by the acid value, m. p. and other properties. The melissyl alc. was identified by analysis

for C and H, and by formation of melissyl acetate with a further recognition of its m. p. and analysis. N. M. NAYLOR

Carbonyls and nitrosyls. IV. HANS REIHLEN, A. GRUHL, G. v. HESSLING AND O. PFRENGLE. *Ann.* **482**, 161–82(1930); cf. *C. A.* **23**, 4674.—The compd. to which Manchot and Gall (*C. A.* **23**, 3870) attributed the formula $FeNO.2MeOH$ is more accurately represented as $Fe_2(NO)_2(OMe)_2OH$. It is decompd. almost exclusively to ferrous salt by dil. H_2SO_4 in the cold if the HNO_2 simultaneously formed is immediately removed. $Ni(CO)_4$, MeOH and NO with a trace of H_2SO_4, with exclusion of moisture and atm. O, give the *compd.* $NiNO.OMe.OH$ + MeOH, green, which readily loses a mol. of MeOH. It does not undergo autoxidation as readily as the Fe compd. but is stable to hydrolysis. $Fe(CO)_5$ and boiling MeOH in ultra-violet light give Fe-, MeOH and the *compd.* $FeCO.OMe.OH$, which tends to lose CO but not MeOH in high vacuum. Long heating of $Fe(CO)_5$ with butadiene gives the *compd.* $Fe(CO)_3.C_4H_6$, b. 20.5 30° in a high vacuum. Less well-defined compds., approx. to $Fe(CO)_3.C_5H_8$, $Fe(CO)_3.(C_5H_8)_2$ and $Fe(CO)_3.(C_6H_{10})_2$, are obtained with isoprene and β,γ-dimethylbutadiene. C. J. WEST

Decomposition of acetic acid in the presence of silica gel. JAMES A. MITCHELL AND F. FAIRBET REID. *J. Am. Chem. Soc.* **53**, 338–43(1931).—In passing AcOH over silica gel the max. yield (29%) of Me_2CO is obtained at 430–60°; above 400° appreciable decompn. of the Me_2CO formed becomes noticeable. With aq. AcOH a greater proportion of the decompd. acid is obtained as Me_2CO; this would indicate that the proportion of H_2O vapor present influences the rate of decompn. of the Me_2CO in accord with the results of Kultashev and Kudryasheva (*C. A.* **19**, 2443). Purified and com. gel were equally effective catalysts. Some of the CO_2 formed results from the reaction $AcOH \rightarrow CH_4 + CO_2$. From 40 to 60% of the Me_2CO originally formed in the reaction is decompd., depending upon the temp. of the reaction. C. J. WEST

The preparation of the ethyl ester of 10-octadecenic acid by partial reduction of the corresponding ester of 9,11-octadecadienic acid and the acid itself as a member of the series of the elaidic acids. J. BÖESEKEN AND R. HOEVERS. *Rec. trav. chim.* 49, 1065–76(1930).—Boeseken *et al.* (*C. A.* **22**, 219; **24**, 2985) have shown that the reaction of Et α-eleostearate proceeds according to Thiele's principle, first with the formation of the Et 10,12 octadecadienate and subsequently with the formation of the Et 10-octadecenate. The present paper deals with the partial hydrogenation of the Et 9,11-octadecadienate, which again proceeds according to Thiele's theory with the formation of the Et 10 octadecenate. Ricinolic acid, prepd. by sapon. of castor oil with alc. KOH, was converted into ricinelaidic acid, m. 52°, by means of 50% HNO_2, contg. HNO_3. The acid was dehydrated by distn. under reduced pressure in the presence of Ni as a catalyst; the yield of 9,11-linolic acid, m. 53°, was, however, only 15%. The Et ester, prepd. in the usual way, b. 156° in the cathodic vacuum, $n_D^{18°}$ 1.4720. The hydrogenation was carried out with Ni as a catalyst at 180°, the process being stopped after addn. of 1 mol. H, and gave the Et 10-octadecenate, d^{18} 0.8757, n_D^{18} 1.4550. On saponn. the octadecenic acid, m. 42° from petr. ether, was obtained, the constitution being established by ozonization in $CHCl_3$, which, after oxidation of the fission products of the ozonide, gave caprylic acid, b. 236°, and sebacic acid, m. 133°. The curve representing the connection between the m. p. and the place of the double bond shows the acid to belong to the elaidic series, especially on comparing the 2-, 6-, 9- and 11-octadecenic acids, which have been recognized as elaidic acids with certainty. C. F. VAN DUIN

Action of maleic anhydride on 9,11-octadecadienic acid and its ethyl ester. The products of the dehydration of ricinoleic acid. J. BÖESEKEN AND R. HOEVERS. *Rec. trav. chim.* 49, 1165–8(1930).—The reaction of Diels (*C. A.* **24**, 356) between compds. with a conjugated system and maleic anhydride also takes place with 9,11-linolic acid and its Et ester, although the formation of 4 isomers is possible (*cis-1-cis-2-cis-3; cis-1-cis-2-trans-3; cis-1-trans-2-cis-3; trans-1-cis-2-trans-3*) the formation of one of these seems to be favored to a degree that a simple compd. and not a mixt. is obtained. The reaction between the 9,11-linolate and maleic anhydride gives a deriv. of the anhydride of tetrahydrophthalic acid, m. 60°, which is hydrogenated *in AcOH with Pt* to the satd. analog m. 27°; the hydrogenation with Ni takes also another course, for after having taken up 1 mol. H, unsatd. compds. are still present (I no.), while the mol. wt., detd. by titration with alkali, is 424 (calcd. 408). On heating maleic anhydride with 9,11-linolic acid, a reaction product m. 88° is formed; both the products m. 60° and 88°, mentioned above, on hydrolysis give a tri-CO_2H acid, which could not be obtained in the cryst. state, only a vitreous mass being obtained. On boiling the latter with Ac_2O the anhydrides m. 60°

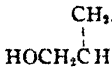
and 88° are formed again. This method has now been used to elucidate the dehydration of ricinoleic acid, which only gives a small quantity of 9,11-linolic acid (cf. preceding abstr.). The reaction product of the dehydration was esterified and brought into reaction with maleic anhydride, the excess of the latter being estd. by titration with alkali of the aq. ext. of the reaction product. In this way it was found that 75% of compds. with a conjugated system were formed; by distn. of the reaction product in a cathodic vacuum a mixt. of esters of linolic acids with 2 sepd. double bonds (9,10 and 12,13) were obtained (15%). The residue of this distn. only gives a small quantity of the compd. m. 60° described above, from which it follows that several linolic acids (9,11) are formed in the dehydration. A small quantity of an aldehydic substance could be isolated from the reaction product before its esterification on cooling at —10° during 24 hrs.; it was not investigated further. C. F. VAN DUIN

Polymerization of methyl esters of high, unsaturated fatty acids. V. Esters containing a four-carbon ring. K. KINO. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding, 444–5(1930)(in German); cf. *C. A.* **25**, 71.—The Me ester, $C_{21}H_{33}CO_2Me$ (5 double bonds), was heated under H_2 at 290–300° for 20 min. The ester of the new, intramolecularly combined mono-CO_2H acid was sepd. from higher-boiling polymers by distn. *in vacuo*. The sapon. no., I no. and mol. wt. of the acid corresponded to a monomeric compd., $d_4^{20.6}$ 0.9192, $n_D^{30.6}$ 1.4820, M. R. 105.75, calcd. for $C_{22}H_{34}O_2Me$ (3 double bonds) 101.27. The acid was hydrogenated, and the solid fatty acid, isolated as the Pb salt from alc., m. 79–9.3°. Though its m. p. was 1° higher, it was probably identical with a previously found compd., which was assumed to contain the 4-C ring. K. H. ENGEL

Products of the action of chlorosulfonic acid on butyryl chloride at room temperature. M. KRAJČINOVIČ. *Ber.* **63B**, 2276–8(1930); cf. *C. A.* **23**, 3662.—The study of the products of the action of $ClSO_3H$ on AcCl and EtCOCl has been extended to the products formed from PrCOCl at room temp. The reaction is gradual, quite slow and accompanied by a continuous evolution of HCl and CO. From the reaction mixt., after decompn. with H_2O, no $EtCH(SO_3H)CO_2H$ could be isolated, as in the case of AcCl and EtCOCl. Extn. with Et_2O yielded Pr_2CO, b. 144°. The results with the 3 chlorides indicate that the greater the no. of C atoms they contain, the fewer no. of mols. condense with each other. Thus, 4 mols. of AcCl condense to form 2-methyl-1,4-pyrone-6-acetyl chloride, 3 mols. of EtCOCl to form α-ethyl-β,β'-dimethylpyronone and only 2 of PrCOCl to form Pr_2CO. Furthermore, the condensation products of AcCl are obtained only at higher temps., whereas those of the EtCOCl and PrCOCl are decompd at the higher temps. and can be isolated only at room temp. C. A. R.

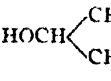
A method of preparation of thio acids, especially chlorothioacetic acid. F. ARNDT AND NADJI BEKIR. *Ber.* **63B**, 2390–3(1930).—*Chlorothioacetic acid*, $ClCH_2COSH$ (I), light yellow, b_{14} 46°, is obtained in 24-g. yield from 50 g. $ClCH_2COCl$ and 1 g. anhyd. $AlCl_3$ treated 8–9 hrs. in ice with dry H_2S. MeCOSH, b. 93°, is similarly obtained in 40% yield from AcCl at an initial temp. of —15°. I is little sol. in H_2O and does not fume when freshly distd. but after some time it begins to decomp. Although all its properties pointed to the structure $ClCH_2COSH$, there is in the literature a hitherto uncontradicted statement that when $ClCH_2COCl$ reacts with mercaptans it is the Cl in the CH_2Cl, not the COCl group, which reacts. Stollé believed that the compd. m. 38° obtained from $ClCH_2COCl$ and *p*-MeC_6H_4SH is $MeC_6H_4SCH_2COCl$ (II) but it is really $ClCH_2COSC_6H_4Me$ (III), as had been assumed 5 yrs. before by v. Auwers and Arndt, for the true II, obtained from *p*-$MeC_6H_4SCH_2CO_2H$ with PCl_5, is a liquid with the typical penetrating odor of acid chlorides and is rapidly hydrolyzed by H_2O to $MeC_6H_4SCH_2CO_2H$, while III is quite stable toward H_2O and is only slowly dissolved by even hot alkali, acids pptg. $MeC_6H_4CH_2CO_2H$, resulting from the combination, in the alk. soln., of the products of hydrolysis (MeC_6H_4SH and $ClCH_2CO_2H$). The product of the reaction between $ClCH_2COCl$ and MeSH is therefore $ClCH_2COSMe$ (IV), and is also obtained from I with CH_2N_2, thus establishing the structure of I. In attempts to prep. thioglycolide from I, it was found that I at first dissolves clear in a little Na_2CO_3 but there soon seps. an oil of penetrating nauseating odor. In 1 expt. on a small scale there was isolated, by extn. with Et_2O, a substance, m. 86°, of the same odor, but this could not be reproduced on a larger scale, the product being for the most part neither distillable nor crystallizable. Apparently, the auto-alkylation of I results only to a minimal extent in the formation of cyclic products of low mol. wt. The $HSCH_2COCl$ isomeric with I is not formed from $HSCH_2CO_2H$ and $SOCl_2$ (Holmberg) and PCl_5 gives a relatively low-boiling (b_{12} 93°) *liquid* (V) having apparently the structure $S(CH_2COCl)_2$.

Cf. IV b. 160°, b_{12} 58°. ***Bis(chloroacetyl) sulfide* (65% from I and 1 mol. $ClCH_2COCl$**



refluxed 1–1.5 hrs. in CCl_4), m. 47°, b_{11} 130°, becomes violet, then dark brown and resinous in a few days, even in sealed tubes, and shows not a trace of the toxic properties of $(ClCH_2CH_2)_2S$. *p-Tolylthioglycolyl chloride* (II), b_{18} 149° (slight decompn.). V fumes in the air and with H_2O evolves HCl with a hissing sound; in sealed tubes it decomps. in a few days to a gelatinous mass and at 120° or in contact with concd. HNO_3 it explodes with formation of a voluminous carbonaceous mass. C. A. R.

Methanetrisulfonic acid. H. J. Backer (with K. H. Klaassens). *Rec. trav. chim.* **49**, 1107–17(1931).—$CH(SO_3H)_3$ has already been prepd.: (1) by Theilkuhl (*Ann.* **147**, 134(1868)) on heating Ca Me sulfate with $H_2S_2O_7$; (2) by Bagnall (*J. Chem. Soc.* **75**, 278(1899)) on sulfonating Ac derivs. of aromatic amines; (3) by oxidation of $HSC(SO_3H)_3$ (Albrecht, *Ann.* **161**, 139(1872); cf. Backer, *C. A.* **24**, 76); (4) by the action of K_2SO_3 on $O_2NCH(SO_3H)_2$ (Rathke, *Ann.* **167**, 219(1873)), which is formed by the action of K_2SO_3 on O_2NCCl_3; it is, however, to be recommended to isolate the $O_2NCH(SO_3H)_2$, which is formed as an intermediate product; (5) on heating $N_2C(SO_3H)_2$ with acids, water or $KHSO_3$ (von Pechmann, *Ber.* **28**, 2382(1895); Fantl and Fisch, *C. A.* **24**, 1841); (6) by sulfonation of $CH_2(SO_3H)_2$. All these methods, except 1, are discussed in the present paper. *Method 6:* On heating $CH_2(SO_3H)_2$ with SO_3 (2.5 mols.) during 5 hrs. at 170°, $CH(SO_3H)_3$ may be obtained as the K salt with 10% yield. *Method 2:* sulfonation of PhNHAc 0.5 mol. AcNHPh is introduced slowly into 600 g. fuming H_2SO_4 contg. 35% SO_3, the mixt. being heated 3 hrs. at 130° with mech. stirring; yield of the tri-K salt 57%; on carrying out the same reaction with succinanilide, a small yield of the same compd. was obtained. *Method 3:* 0.1 mol. $HSC(SO_3K)_3$, in 1 l. water is oxidized at room temp. by a current of Cl with the gradual addn. of 80 g. $KHCO_3$; yield 90%. *Method 4:* $O_2NCH(SO_3H)_2$ was prepd. according to Rathke (*loc. cit.*) by adding 82 g O_2NCCl_3 gradually to 450 g. K_2SO_3 in 900 cc. water, heated to 75°, and keeping the temp. at 80°; yield 40% of the anhyd. di-K salt, which dissolves in water at 25° to the extent of 1.16%. The normal strychnine salt of $O_2NCH(SO_3H)_2$ crystallizes with 3.5 H_2O, the free acid itself with 2 H_2O while the normal Na and Tl salts crystallize without H_2O; both the latter salts are easily sol. in water. On heating the K salt with K_2SO_3 in a sealed tube at 140°, $CH(SO_3K)_3$ is obtained in 67% yield. *Method 5:* $N_2C(SO_3K)_2$, prepd. according to von Pechmann (*loc. cit.*), may be converted into $CH(SO_3H)_3$ by the action of $KHSO_3$ at 60° and finally on the water bath (yield 62%), decomp. the compd. with water or introducing it into dil. HCl, the latter reaction giving a 40% yield. On introducing the diazo compd. into concd. HCl at 0°, $ClCH(SO_3H)_3$ is obtained. The following salts of $CH(SO_3H)_3$ and the acid itself were prepd. in the usual way: The *tri-acid* with 3.5 H_2O, m. 156°; the *tri-K salt*, rhombic prisms with 1 H_2O; 100 g. of water dissolve at 25°, 1.202 g. of the anhyd. salt and 1.261 g. of the crystd. salt. Crystallographic properties (P. Terpstra): rhombic system, bisphenoidic class D_2; $a:b:c$ = 0.9977 : 1 : 1.3604. Forms: a = (100); b = (010); c = (001); p = (101); m = (110); o = (111); ω = (1$\bar{1}$1); q = (011); s = (121); angles: $a:m$ = 44° 56′; $c:p$ = 52° 38′; $o:s$ = 19° 28′, $b:\omega$ = 51° 34′; $c:q$ = 52° 36′; $o:s$ = 19° 22′. The crystals obtained by evapn. at ordinary temp. have a larger dimension in the direction of the b-axis. The crystals show a marked piezoelectricity; the plane of the optical axes is (001); the a-axis is the sharp bissectrix; $\rho < v$. For Na light $2E$ 83° 1′; α = 1.513; β = 1.5253; γ = 1.5270; $2V$ = 51° 45′. The *tri-Tl salt* also contains 1 H_2O; crystallographic properties (P. Terpstra): rhombic system, bisphenoidic class; $a:b:c$ = 0.9971 : 1 : 1.3009, forms: m = (110); p = (101); q = (011); ω = (1$\bar{1}$1); o = (111); the crystals possess either the form o or the form ω, which have never been found to occur in the same crystal. Angles: $m:m$ = 90° 10′; $p:p$ = 105°4′; $q:q$ = 104°54′; $\omega:\omega$ = 123°0′; $p\omega$ = 38° 20′; $\omega:q$ = 38°29′. The plane of the optical axes is (001); the sharp bissectrix (010). By means of a prism formed by (1$\bar{1}$1) and (1$\bar{1}$1) the refractive index β has been found to be 1.739, 1.743, 1.768 for λ = 578, 546, 436, resp. The crystals are piezoelectrical. The *tri-Ag salt* contains 1 H_2O; the *Ba salt*, 9 H_2O; the latter is difficultly sol. in water, only to the extent of 0.1%. On mixing without precautions the solns. of the K salt and $BaCl_2$, a *double salt of Ba and K* is obtained, $CHO_9S_3KBa.3H_2O$, which, after several recrystns. from a large amount of water, gives the pure Ba salt. The *Ca salt* contains 12 H_2O and the *La salt* 6 H_2O (cf. Backer and Klaassens, *C. A.* **24**, 4729). C. F. van Duin



The preparation, properties and uses of glycerol derivatives. I. Glycerol ethers. A. Fairbourne, G. P. Gibson and D. W. Stephens. *Chemistry and Industry* **49**, 1021-3(1930).—F., G. and S. describe the prepn. of derivs. of glycerol: *monochlorohydrin*, $CH_2ClCH(OH)CH_2OH$ (I), in 86% yield from glycerol + 2% HOAc + HCl gas at 100°, b_{15} 98–100°, b_{40} 141, d_4^{25} 1.313; $CH_2ClCH(OH)CH_2Cl$ (II), made as I at 130°

(yield, 82%), b_{40} 92°, b_{760} 176°, d_4^{25} 1.359; $O.CH_2.CHCH_2Cl$ from II by the action of NaOH (yield 90%), b_{760} 116–7°, d_4^{20} 1.18. $C_3H_5(OH)_2ONa$ (III) was prepd. by heating equimol. quantities of glycerol and NaOH. Monoethers are prepd. in good yields by ROH and NaOH on I. α- and β-Monoethers as well as the di- and triethers can be prepd. from III and Me_2SO_4. In the following is listed the b. p. at diminished pressure, followed by b_{760}, d_4^{25}, n_D^{25}, and soly. in water: α-Me, b_{40} 135.5–6°, 220°, 1.111, 1.442, miscible; β-Me, b_{10} 147–8°, 230°, 1.124, 1.446, miscible; Et, b_{10} 112–3°, 222°, 1.063, 1.441 (20°), miscible; iso-Am, b_{10} 136–8°, 254°, 0.976, 1.440, 1%; $PhCH_2$, b_2 164–6°, —, 1.130, 1.530, 1%. Tolyl (mixt. *o*, *m*, *p*), b_1 155–160°, —, 1.127, 1.534, 1%. The same information is given for the following glycerol diethers: α,β-di-Me, b_{40} 99–100°, 180°, 1.016, 1 421, miscible; α,γ-di-Me, b_{40} 88–9°, 169°, 1.004, 1.417, miscible; di-Et, b_{60} 108–110°, 191°, 0.952, 1.419 (23°), miscible; diiso-Pr, b_{60} 123–4°, 199°, 0.914, 1.418, 20%; di-Pr, b_{60} 135–7°, 218°, 0.926, 1.424, 8%; diiso-Am, b_4 120–1°, 265°, 0.901, 1.431, 1%; dibenzyl, b_2 198–204°, —, 1.101, 1.547, insol; ditolyl (mixed), b_{20} (steam) 200–210°, —, 1.101, 1.552 (23°), insol.; di-*o*-tolyl, b_2 195–7°, —, 1.111, 1.556, insol.; di-*m*-tolyl, b_2 205–7°, —, 1.105, 1.558 (24°), insol.; di-*p*-tolyl, solid m. 88°, insol. in H_2O. Glycerol triethers: tri-Me, —, 148°, 0.937, 1.401, miscible; tri-Et, b_{60} 103–5°, 181°, 0.886, 1.407, 10%. Glycerol ether acetates: α-Me diacetate, b_{40} 139–40°, 228°, 1.097, 1.422, miscible; β-Me diacetate, b_{40} 144–5°, 232°, 1.100, 1.424, miscible; Et diacetate, b_{10} 117–9°, 234°, 1.062, 1.421, 10%; α,β-di-Me acetate, b_{10} 108–9°, 195°, 1.027, 1.414, miscible; α,γ-di-Me acetate, b_{40} 105–6°, 191°, 1.025, 1.413, miscible; di-Et acetate, b_{60} 127–9°, 208°, 0 979, 1.414, 13%. These compds. may be used as solvents for oils, nitrocellulose, gums, resins. A brief discussion of their use as lacquer solvents is given. G. R. YOHE

A new acetoneglycerol (α,α′-isopropylideneglycerol). NEAL M. CARTER. *Ber.* **63B**, 2399–400(1930).—The structure I has been established for ordinary acetoneglycerol by Irvine, Macdonald and Soutar. Recently, Bergmann and C. described a method of prepg. β-glycerides by which they obtained $BzOCH(CH_2OH)_2$, m. 72°, to establish the structure of which they condensed it with Me_2CO to β-benzoyl α,α′-isopropylideneglycerol (II). This proved to be different from the known α-benzoyl acetoneglycerol. By sapong. II with alkali, C. has now obtained *α,α′-isopropylideneglycerol* (III), b_{12} 90–1°, d_4^{20} 1.0911, n_D^{20} 1.4427 (the corresponding values for I, detd with the same instruments, are 87–8°, 1.0691, 1.4352). Rebenzoylation gave 70% II (probably the true yield was much higher, since the great soly. of II in all org. solvents makes its quant isolation difficult).

C. A. R.

Oxidation-reduction potentials of certain sulfhydryl compounds. EARL K. FISCHER. *J. Biol. Chem.* **89**, 753–63(1930).—The oxidation-reduction potentials of $HSCH_2CO_2H$, $HSCH_2CH_2OH$ and $HSCH_2CH(OH)CO_2H$ can be derived from the concn. of hydrion and of reduced substance (−SH compd.) according to the equation of Dixon and Quastel (*C. A.* **18**, 380), by selecting an arbitrary value for E_1. By electrometric titration with I_2 and $K_3Fe(CN)_6$, however, it is shown that the potentials depend also on the presence of an oxidized form, presumably an intermediate compd., when the p_H is kept const. For the above compds. and cysteine, the value of E_0 between p_H 3 and 7 = 0.44 v. approx. K. V. THIMANN

Mechanism of the formation of hydrazones from diazonium compounds and alkyl derivatives of acetylacetic, malonic and cyanoacetic esters. G. FAVREL *Bull. soc. chim.* [4], **47**, 1290–1300(1930).—According to Japp and Klingemann (*Ber.* 20, 2942(1887)) diazonium compds. react with alkylacetylacetic esters in alk. soln. to form hydrazones. J. and K. represent the reaction in 1 step. F. believes that it should be represented as taking place in 3 steps: (1) formation of H_2O and a mixed azo compd.; (2) action of the mixed azo compd. with NaOH to give AcONa and a new mixed azo compd.; (3) the mol. rearrangement of this new azo compd. to give a hydrazone isomeric with it. F. has attempted to isolate the mixed azo compd. formed in the first step. *m*-$C_6H_4(NH_2)NO_2$ (0.1 mol.) was diazotized in HCl, and excess AcONa soln. added to give an AcOH soln. of the diazonium hydroxide (I). Powd. $CaCO_3$ was then added to this soln. at 0°, until it contained 0.05 mol. AcOH per 0.1 mol. of I. An equimol. quantity of $CHEtAcCO_2Et$ in 30 cc. Et_2O was added, and the whole kept at 0° for 30

min. The sirup from the Et_2O ext. gave after 3 months crystals of Et *m*-nitrophenylazoethylacetylacetate, *m*-$O_2NC_6H_4N$:NCEtAcCO$_2$Et, m. 132–3°, pale yellow, decompd. by dil. alkali and by H_2O. From I and CHMeAcCO$_2$Et was obtained *m*-$O_2NC_6H_4N$:NCMeAcCO$_2$Et, m. 122–3°, decompd. by dil. alkali. Diazonium compds. of toluidines, chloroanilines, bromoanilines, etc., gave with alkylacetylacetic esters liquids which could not be purified, and which were probably mixed azo compds., since they were hydrolyzed by H_2O or dil. alkali to hydrazones. Using the method of condensation described above, the tetrazonium hydroxide (II) formed from benzidine gave, when condensed with CHEt(CO$_2$Et)$_2$ (III), [C_6H_4NEtN:C(CO$_2$Et)$_2$]$_2$, m. 112–4°; with CHMe(CO$_2$Me)$_2$ II gave [C_6H_4NMeN:C(CO$_2$Me)$_2$]$_2$, m. 103–4°. The tetrazonium hydroxide prepd. from tolidine gave, when condensed with III, [C_6H_3MeNEtN:C(CO$_2$Et)$_2$]$_2$, m. 118–20° (decompn.). The tetrazonium hydroxide of bianisidine when condensed with III gave [C_6H_3(OMe)NEtN:C(CO$_2$Et)$_2$]$_2$, m. 115–6°. Thus, tetrazonium hydroxides reacting with alkylmalonic esters give *N*-alkyldihydrazones which are isomeric with the mixed azo compds. which one might expect to be formed. The diazonium compd. of *p*-$BrC_6H_4NH_2$ gave with CHEt(CN)CO$_2$Et (IV), *p*-BrC_6H_4NEtN:C(CN)CO$_2$Et, m. 56–7°, and *p*-BrC_6H_4NN:CEt(CN)CO$_2$Et (formula given by F., but should probably be *p*-BrC_6H_4N:NCEt(CN)CO$_2$Et), m. 111–2°. I with CHMe(CN)CO$_2$Et gave *m*-$O_2NC_6H_3$NMeN:C(CN)CO$_2$Et (F. gave *m*-$O_2NC_6H_4$NMeN:C(CN)CO$_2$Et), m. 118°, and an isomer in the form of a mixed azo compd., *m*-$O_2NC_6H_4N$:NCMe(CN)CO$_2$Et, m. 197–8°. PhN$_2$OH (V) and IV gave a *N*-ethylhydrazone (prepd. by Kruckeberg, *J. prakt. Chem.* **47**, 591(1893)), m. 72°, and the isomeric mixed azo compd., m. 126°. V with CHAc(CN)CO$_2$Et gave PhN:NCAc(CN)CO$_2$Et, m. 129–30°.

LOUISE KELLEY

Some **hydroxy acids of the sugar group. II.** K. REHORST. *Ber.* **63B**, 2279–92 (1930), cf. *C. A.* **22**, 1331.—It was shown in the 1st paper that by avoiding the presence of H_2O the polyhydroxymonocarboxylic acids of the sugar group can be obtained in cryst. form instead of their lactones; immediately after liberation from their salts, EtOH and a higher-boiling alc. (Bu, iso-Bu or Am) are added and on evapn. the H_2O is removed along with the EtOH and the free acid crystallizes from the remaining higher boiling alc. As a rule these acids in H_2O apparently change into their lactones even at room temp. but it has been found that with *d*-gluconic acid (I) this lactonization depends on the temp.; if the soln. is evapd. directly on a boiling H_2O bath the free acid separates exclusively. This greatly simplifies its prepn. *l*-Arabonic acid (II) has been obtained in cryst. form by the method described above (yield, 67% after recrystn. from EtOH or MeOH). It is not esterified by refluxing 1 hr. in 30 parts MeOH while the lactone is esterified by MeOH. The cryst. II, in which the free CO_2H group can be titrated directly with alkali, m. around 118–9° and shows $[\alpha]_D$ —10.02° 3 min. after soln., increasing to —7.11° in about 2.5 hrs. and then decreasing again to —11.6° in 21 days. Along with the change in rotation there is a decrease of the directly titratable acidity while an excess of alkali is used up in the cold, pointing to the presence of lactone. The course of the titration curve indicates that at least 2 substances are formed from the cryst. II in H_2O. Levene and his co-workers had concluded, from the similar behavior of other polyhydroxymonocarboxylic acids, that these acids regularly change in H_2O in part into 2 different lactones (γ and δ). In some cases there has been isolated, in addn. to the previously known γ-lactone, a 2nd lactone and although it has not been proved that these isomers are δ-lactones, a consideration of the Loschmidt and Kekulé models of org. compds. shows that alc. groups on the δ-C atom lie in a peculiarly favorable position for lactone formation. Furthermore, the directions of the rotation of the new lactones hitherto isolated obey the 1st Hudson acid rule only if they are considered as being δ lactones. According to the views of Levene and Simms the change in rotation of the free acids is due to their partial conversion into the 2 lactones; the formation of the γ-lactone is slow and proceeds for several hundred hrs. while the δ-lactone formation, which is at first 8 times faster, stops in a few hrs. As a result, when the relatively weakly rotating acid is dissolved, the δ-lactone is at first formed almost exclusively and when its formation ends after a few hrs. there is as yet hardly any γ-lactone in the soln. The observations made on the cryst. II permit of still further extending the views of L. and his collaborators. If the 2 lactones rotate in the same direction, which according to the Hudson acid rule will be the case when the HO groups on the γ- and δ-C atoms are in the *cis*-position to each other, then a reversal in the direction of the change in rotation is hardly to be expected (*e. g.*, with cryst. I and *l*-mannonic acid liberated from its salts). If, however, the HO groups are in the *trans*-position to each other, the lactones will, by the H rule, rotate in different directions, and the rotation of the acid, when dissolved, will at first change in the direction of that of the δ-lactone and later of that of the

γ-lactone. Such reversals in the change in rotation have been observed with *d*-galactonic, *d*-gulonic and *d*-glucoheptonic acid. If these views are correct, of the 16 possible hexonic acids, these reversals would be expected only with the idonic and talonic, in addn. to the galactonic and gulonic acids. Nothing is known as to the course of the rotation of *d*-idonic acid and no reversal has been noted with cryst. *d*-talonic acid; possibly the rotation of the δ-lactone is of the same order of magnitude as that of the acid, or the cryst. acid was contaminated with a small amt. of lactone not detectable by analysis. If this reasoning can be applied to the pentonic as well as to the hexonic acids, the reversal in the change in rotation observed with II would indicate that the γ- and δ-HO groups are in the *trans*-position to each other. Probably all 8 pentonic acids will show such reversals. There are no data in the literature on this point; R. has found for cryst. *d*-xylonic acid $[\alpha]_D$ —1.9° ⟶ —3.6° ⟶ 20.2°. By analogy, the γ lactones of the *d*-series of the tetronic acids are probably *d*-rotatory. All attempts to prep. cryst. *l*-rhamnonic acid (III) by the method given above failed; always the δ-lactone crystd. in pure form and generally in good yield. Only by very rapid work was it possible to obtain needles which from their compn. apparently consisted of about equal parts of acid and lactone which could not be sepd. Their rotation, however, agreed with that given by Schnelle and Tollens ($[\alpha]_D$ —7.7°) for the acid liberated from its Sr salt. A repetition of their work showed that the acid has $[\alpha]_D$ 5.8°, but when prepd. from the crystd. lactones (either γ or δ) it shows $[\alpha]_D$ 11.0°. As the 2 lactones are *l*-rotatory, in agreement with the H. rule, the rotation falls rapidly to 0°, then becomes *l*-rotatory and finally attains a const. value, $[\alpha]_D$ —34.7°. As expected, there is no reversal in the direction of the change in rotation. C. A. R.

The effect of weak alkalies on the trioses and on methylglyoxal. H. A. Spoehr and Harold H. Strain. *J. Biol. Chem.* **89**, 503–25(1930); cf. following abstr. —The general chem. reactions of $CH_2(OH)CH(OH)CHO$ (I), $CH_2(OH)COCH_2OH$ (II), and MeCOCHO (III), have been studied in view of possible relationship to the oxidation of carbohydrates. I, m. 141–2° after prolonged drying, was prepd. by Evans and Hass' method (*C. A.* **20**, 3692) and could be quantitatively oxidized by Cajori's I_2 method (*C. A.* **17**, 783) to $CH_2(OH)CH(OH)CO_2H$. Phosphotungstomolybdic acid is reduced by I and II and also by fructose and xylose. I and II are oxidized by Benedict's soln., requiring 1.68 and 1.63 atoms O, resp., and are completely reduced by Adams' catalyst in the presence of Na_2HPO_4 or NaH_2PO_4. II reacts with I_2 to form smaller mols. of high reducing power and cannot, therefore, be detd. by Cajori's method. For III, acetol (cf. Nef, *Ann.* **335**, 247, 1904) was treated with $Cu(OAc)_2$ for 3–4 weeks, filtered from Cu_2O, distd. *in vacuo* at 35°, extd. with Et_2O, dried, the Et_2O distd. off, and the residual gum desiccated over KOH and fractionated *in vacuo*. Detns. of III by different methods differ by 3–4%; Fischler and Boettner's method (*C. A.* **22**, 2901) gives erroneous results unless a large excess of NaOH and I_2 is present. In Na_2HPO_4 soln., I and II undergo slow condensation, and the reducing power of II toward Benedict's soln. or I_2 decreases. The reducing power of III under the same conditions increases 15%, but the amt. of III in soln., detd. by the *m*-nitrobenzohydrazide, falls to 0 in 8 days at 25°, with corresponding formation of CHI_3-reacting groups. K. V. Thimann

The effect of amines on the conversion of trioses into methylglyoxal. Harold H. Strain and H. A. Spoehr. *J. Biol. Chem.* **89**, 527–34(1930); cf. preceding abstr.—MeCOCHO (I) reacts with *m*-nitrobenzohydrazide (II) in dil. HOAc to produce *methylglyoxal m-nitrobenzoylosazone*, $C_{17}H_{14}O_6N_6$ (III), only slightly sol. in org. solvents, decomps. 280°. By means of this reagent I can be quantitatively detd. If $CH_2(OH)CH(OH)CHO$, which forms no such ppt., be treated with an amine, and then with II, an immediate ppt. of III is produced. The reaction is catalyzed by many aromatic amines, but not by amino acids. In the absence of II, I accumulates in the soln. up to 50% of the theoretical yield. $CO(CH_2OH)_2$ reacts slowly with II to give a ppt. of III after several days. $PhNH_2$ also catalyzes this reaction. The *4,4-diphenylsemicarbazone* of I, $C_{28}H_{26}O_2N_6$, m. 161–2°, was also prepd. but was not suitable for use in its detn. K. V. Thimann

Transformation of pyruvic acid as a function of time and temperature. M. Garino, G. Balletto, F. De Thierry and C. Becchi. *Gazz. chim. ital.* **60**, 592–605(1930); cf. *C. A.* **25**, 494.—Systematic expts. were carried out to obtain quant. data on the stability of $AcCO_2H$ at different temps. (0–40°) in N and in air, a subject which is of importance because of the fact that in syntheses with $AcCO_2H$ unexplained variations in yields have been obtained (resulting from the age and condition of the $AcCO_2H$). The results show that $AcCO_2H$ remains unaltered over a period of several months only if it is kept in the solid state not above 0°. At temps. near the m. p. it gives evidence of decompn. in a very short time. In the liquid state its rate of decompn. is proportional to

the temp. After 24 hrs. at 25°, the m. p. diminishes greatly and after 20–5 days the substance can no longer be crystd. After 2 days at 40°, the m. p. is a min. and after 5 more days $AcCO_2H$ is no longer present. During the initial stage of decompn., the acidity does not change, while the elec. cond. varies but slightly, and the m. p. diminishes considerably. In the later stage of decompn., the acidity diminishes greatly (a decrease of 11% of the original acidity), the substance is no longer crystallizable and an unidentified fluorescent *compd.* is formed. The m. p. of $AcCO_2H$ purified by redistn. was 13.62° (cf. *Bull. soc. chim.* [3], **13**, 336(1895)), and the dissocn. const. K was 0.00593. It is probable that in the liquid state $AcCO_2H$ is in equil. with its enolic form: $AcCO_2H \rightleftharpoons CH_2:C(OH)CO_2H$ (cf. Henri and Fromageot, *C. A.* **20**, 900) and that condensation products are formed: $2AcCO_2H \longrightarrow HO_2CCOCH_2CMe(OH)CO_2H$ and the presence of a new compd. lowers the m. p. of the mixt. Though the acidity (tested by NaOH) does not change, the elec. cond. diminishes because of the increase in mol. wt. The formation of $\overset{\displaystyle CH:C(OH).CO.O.}{\displaystyle\vert\!\!\vert\!\!\vert\!\!\vert}\!\!CMeCO_2H$ (cf. *Ann.* **317**, 6(1901)) would also account for the measurements in the present paper. Decompn. is more rapid in air than in N.

C. C. DAVIS

α,α'-Dimethylsuberic and α,α'-dibromo-α,α'-dimethylsuberic acids. CATHERINE C. STEELE. *J. Am. Chem. Soc.* **53**, 283–9(1931).—Details are given for the prepn. of $Br(CH_2)_4Br$ from the glycol, HBr and H_2SO_4 and for $MeCH(CO_2Et)_2$ from $MeCH(CN)CO_2Et$; condensation of these 2 compds. with Na gives 40% of *tetra-Et dimethylhexa-tetracarboxylate*, b_8 210–7°; hydrolysis and removal of CO_2 give 2 isomeric forms of α,α'-dimethylsuberic acid, *A* (I), m. 132–3°, and *B* (II), m. 91–2°; di-Et ether, b_{25} 178–80°. I gives a *di-Br deriv.*, m. 200–1°; *di-Me ester*, b_{20} 216–9°, turns brown on exposure to the air. II gives the same di-Br deriv. Attempts to form a cyclohexane ring by removal of Br with Cu-bronze and mol. Ag were unsuccessful. No attempt was made to det. which was the *dl*- and which the *meso*-form of the acid. C. J. WEST

Preparation of ethyl aminomalonate. V. CERCHEZ. *Bull. soc. chim.* [4], **47**, 1282–7(1930).—The procedure of Piloty and Nerensheimer for the prepn. of $NH_2CH(CO_2Et)_2$ (I) by the reduction of $HON:C(CO_2Et)_2$ in ether with Al-Hg has been modified in several respects. Into a 3-necked flask provided with reflux condenser, dropping funnel and mech. stirrer, contg. 25 g. $HON:C(CO_2Et)_2$ and 200 cc. of *ordinary* ether, was introduced 6 g. of Al plates, 0.3 × 8 × 25 mm., amalgamated by the aid of $HgCl_2$. On initiation of the reaction, 36 g. H_2O was added, drop by drop, over a period of 5 hrs. the ether being kept boiling gently, so that the Al was totally pptd. as a grey powder. The ether soln., freed from Al, was evapd., and the residue, when distd. *in vacuo*, gave 65% of I, stable after redistn., d_4^{18} 1.100, n_D^{18} 1.4353, M_D 41.55, calcd. 41.31; *oxalate*, $CH(CO_2Et)_2.(CO_2H)_2$, m. 138°. C. R. ADDINALL

Some direct derivatives of ethyl aminomalonate. V. CERCHEZ. *Bull. soc. chim.* [4], **47**, 1287–9(1930); cf. preceding abstr.—$H_2NCH(CO_2Et)_2$ (I) gives, by virtue of its NH_2 group, a no. of derivs. Its *urea* (II), prepd. from I and pulverized KOCN in 50–70% yield depending on the purity of the KOCN used, m. 169° (173° given by Johnson and Nicolet, *C. A.* **8**, 1278). II (4 g.) when heated in 400 g. 25% HCl (*d* 1.035 approx.) for several hrs. gave pure hydantoin, m. 119° (90% yield). II is preferable to the urea of $H_2NCH(CO_2Et)_2$ for this prepn., since it is more stable and more easily obtainable. *Phenylurea* of I, prepd. from I and PhNCO, m. 117° (cf. 112–4° given by Gatewood, *C. A.* **19**, 2810). *Carbethoxy deriv.*, from I and a slight excess of $ClCO_2Et$ in the presence of NaHCO, m. 61.2° (63° given by Johnson and Nicolet, *C. A.* **8**, 3787). *Diamide*, prepd. in 60% yield from I and aq. NH_3 satd. at 0°, m. 197° (192° given by Piloty and Nerensheimer *Ber.* **39**, 514(1906)). LOUISE KELLEY

The preparation of ethyl isonitrosomalonate. V. CERCHEZ. *Bull. soc. chim.* [4], **47**, 1279–81(1930).—$HON:C(CO_2Et)_2$ (I) can be prepd., in good yields, directly from $CH_2(CO_2Et)_2$ by the action of HNO_2, the acid being formed in the reaction mixt. by stirring $NaNO_2$ into $CH_2(CO_2Et)_2$ in AcOH, and by operating at room temp. in the proportions of 3 mols. HNO_2 to 1 mol. $CH_2(CO_2Et)_2$. To 160 g. $CH_2(CO_2Et)_2$ in 180 g. of glacial AcOH 190 g. of $NaNO_2$ in the least possible amt. of H_2O was added during the course of one day. After sepn. from the aq. layer, the org. layer was dild. with 2 vols. of Et_2O, neutralized with extremely dil. Na_2CO_3, washed 3 times with a little H_2O, and, after removal of the Et_2O, was distd., giving 80–90% I, b_{12} 172°, n_D^{18} 1.4544, d_4^{18} 1.182, M_D 43.34, calcd. 43.18. C. R. ADDINALL

Supernumerary isomers. IV. Alleged isomerism of cyclic oxalic acid esters. ERNST BERGMANN AND HANS A. WOLFF. *J. prakt. Chem.* **128**, 229–33(1930); cf. *C. A.* **24**, 4025.—The existence of more than 1 ethylene ester of $(CO_2H)_2$ (cf. Chichibabin,

C. A. **23**, 1114) cannot be confirmed, all samples prepd. m. 143°. MeO_2CCOCl and $(CH_2OH)_2$ in C_6H_6, boiled about 3 hrs., give *Me β-hydroxyethyl oxalate* (I), m. 166° (decompn.); distn. *in vacuo* gives the ethylene ester, m. 143°. The product of Tilicheiev (*C. A.* **18**, 970), m. 162°, which he believed to be an isomeric ethylene ester, is believed to be I. C. J. WEST

Synthesis of cyanic acid and urea by ammoniacal oxidation of carbon. GEORGES LAUDE. *Compt. rend.* **191**, 1135–7(1930); cf. *C. A.* **24**, 2990.—HOCN was formed by the ammoniacal oxidation of C prepd. from either camphor or C_2H_2. Each oxidation was carried out as follows: 0.1 g. C, 1 g. Cu powder, 30 cc. concd. NH_3 soln., 20 g. $KMnO_4$ (added in 4 portions), temp. 40–45°, time of oxidation 30 hrs. The HOCN formed was converted into urea, which was detd. by means of xanthydrol. The yields of HOCN were 11.39 g. per 100 g. of camphor C, and 6.3 g. per 100 g. of acetylene C. The latter C is probably a mixt. of amorphous C and graphite, which would explain why it is less easily oxidized than is the camphor C. LOUISE KELLEY

Methyl *N*-formylcarbamate. I. J. RINKES. *Rec. trav. chim.* **49**, 1126(1930). On boiling 5 g. NH_2CO_2Me during 2 hrs. with 25 g. 100% HCO_2H, Me OHCNHCO$_2$Me m. 90–1° after crystn. from benzene, was obtained, which was identical with the compd obtained by ozonization of $PhCH{:}CHNHCO_2Me$. The yield was 1.5 g., but can undoubtedly be increased by altering the amount of HCO_2H and the time of heating. C. F. VAN DUIN

Sugars with branched carbon chains. II. Constitution and configuration of apiose. OTTO TH. SCHMIDT. *Ann.* **483**, 115–23(1930); cf. *C. A.* **24**, 2112.—Previous work, especially by Vongerichten, had shown that apiose is oxidized by Br to apionic acid, which in turn is reduced to a $C_4H_7CO_3H$, provisionally identified as $Me_2CHCH_2CO_3H$. The present work confirms this and thus establishes the constitution of apiose as $(HOCH_2)_2C(OH)CH(OH)CHO$. Consideration of the optical properties of the sugar and its derivs. shows that it must possess the same configuration as *d*(−) lactic acid. Apiose was obtained as a clear, light yellow sirup with α_D^{15} 5.6° (2.4812 g. in 25 cc. H_2O), purified through the benzylphenylhydrazone, m. 137° S°, α_{579}^{25} −78.5° (C_5H_5N *c* 4.5875), α_{546}^{20} −94° (C_5H_5N, *c* 5.020). Oxidation with I-BaI_2 in 0.4 *N* Ba(OH)$_2$ and boiling with $CaCO_3$ give *Ca apionate*, crystg. with 2 mols. H_2O. Reduction with HI and P gives $Me_2CHCH_2CO_2H$, identified as the *p-bromophenacyl ester*, m. 68°; the normal acid ester m. 74°. C. J. WEST

Isomerization of the hydroxy aldehydes. III. Transformation of glucose into ketose (fructose). S. DANILOV, E. VENUS-DANILOVA AND P. SHANTAROVICH. *J. Russ. Phys.-Chem. Soc.* **62**, 494(1930); *Ber.* **63B**, 2269–74(1930); cf. *C. A.* **24**, 1096.—Glucose heated in org. bases, especially pyridine and quinoline, gives neutral products consisting of only glucose and fructose without any admixed mannose. In aq. pyridine and aq. alc. quinoline the rearrangement does not proceed so smoothly; 1–2% of org. acids is formed and mannose could be detected. C. A. R.

Halogenoses of the β-series and their use for syntheses. V. β-Acetochlorogalactose and β-acetochloroxylose. HANS HEINRICH SCHLUBACH AND ROLF GILBERT. *Ber.* **63B**, 2292–7(1930); cf. *C. A.* **23**, 4932.—Bertho (*C. A.* **24**, 3761) recently described a β-azidoacetoglucose whose rotation agrees well with the value calcd. by the Hudson method, whereas the β-acetochloroglucose (I) discovered by Schlubach has a rotation 33° higher than that calcd. by the H. rule. S. had concluded that the H. rule does not hold for I, while B. suggests that the I might not have been pure. Also, Micheel and Micheel (*C. A.* **24**, 2727) were unable to prep. β-acetochloromannose by the S. method (treatment of the corresponding Br deriv. of the α-series with AgCl); they obtained the isomeric α-acetochloromannose. To test the extent of the applicability of the method of prepn. and to obtain new data on the validity of the optical superposition rule, S. and G. have subjected the I to a thorough optical investigation and prepd. the hitherto unknown *β-acetochlorogalactose* (II) and *β-acetochloroxylose* (III) by the above method. The prepn. of I has been so improved that an av. yield of 47% is obtained. Some 300 g. was prepd. in this way and a large amt. was carefully purified. After the rotation no longer changed on recrystn. it was crystd. twice more from Et_2O and C_6H_6; it then showed $[\alpha]_D^{23}$ −18.6° (CCl_4, *c* 1.0), *i. e.*, only 1.2° lower than previously reported. II, after repeated careful purification, m. 93–4°, $[\alpha]_D^{20}$ 5.8° (CCl_4, *c* 1.036). The rotation calcd. by the H. rule is −39°, *i. e.*, the discrepancy between the observed and calcd. values for I is also found in II. Just as I yields a cryst. tetraacetyl-α-glucose (IV), the prepn. of which has been materially improved by adding $AgNO_3$ to speed up the reaction still more, so II gives the hitherto unknown *tetraacetyl-α-galactose* (V), m. 133°,

$[\alpha]_D^{21}$ 144.4° ($CHCl_3$, *c* 0.982), falling immediately on addn. of a drop of NH_4OH to the const. value 90.7 ± 1.0° (*c* 0.992). V is certainly different from the Skraup and Kremann compd. assumed by Hudson and Johnson to be the α-deriv. The half-value times for the change in rotation in abs. MeOH and in Et_2O are about the same for II as for I, showing that epimerism of the 4th C atom has practically no influence on the rearrangement velocity. While I and II thus show a close analogy to each other, III gave an entirely different picture. Considerable difficulty was encountered in its prepn. Because of its unusually strong tendency to rearrange, the rearranging influence of the AgCl is strongly marked and the reaction must be carried out with the purest α-acetobromoxylose, highly active AgCl and in the shortest possible time; these unfavorable factors are partially neutralized, however, by the crystg. power of the III. The pure III m. 112-3°, $[\alpha]_D^{24}$ −131.0° (CCl_4, *c* 1.038); the value calcd. by the H. rule is −99°. As Hudson has frequently explained lack of agreement with his system by assuming that the 2 members of a given pair of compds. do not have the same ring system, S. and G. have attempted to prove that III has the same ring system as the known α-compd., and since H. does not consider the methylation method reliable for this purpose, S. and G. used 2 different methods. With AgCl they effected a smooth transformation of III into the α-compd., and from the 2 isomers they obtained under identical conditions (treatment with aq. Me_2CO and Ag_2CO_3) the same triacetyl-α-xylose described by H. As it seems highly improbable that a change in the ring would occur under these very mild conditions, S. and G. believe it is established that III and the α-compd. have the same ring structure. From these results they conclude that the far-reaching deductions as to ring structure made by H. are not justifiable on the basis of the superposition rule alone. VI. **Crystalline halogenoacetyl derivatives of *h*-galactose.** Hans Heinrich Schlubach and Vilma Prochownick. *Ibid* 2298-301.—S. and P. have been unable to hit upon the conditions necessary to obtain cryst. β-acetochloro-*h*-galactose directly (I) by Hudson and Johnson's method, but after obtaining seed material by the Fischer and Armstrong method (treatment with anhyd. liquid HCl) they were able to prep. I, although in poor yield, by the method of H. and J. From its rotation and behavior in solvents, it undoubtedly belongs to the β-series. It is entirely different from the isomeric α-galactose (II) (see preceding abstr.). The half-value time for its change in rotation in the $CHCl_3$ of the German Pharmacopea VI (about 1% EtOH) is about 12 hrs., in abs. MeOH less than 2 min.; the corresponding values for β-acetochloro-*n*-glucose are 23 hrs. and 5½ min., and as the change in rotation of II is of the same order of magnitude, I in this respect also shows the increased lability characteristic of *h*- as compared with *n*-derivs. Hudson and J. tried in vain to prep. a Br deriv. of pentaacetyl-*h*-galactose, but S. and P. by the action of liquid HBr at room temp. for 2 hrs. obtained a *di-Br deriv.* (III), m. 83-4.5°, $[\alpha]_D^{20}$ −116.2° (CCl_4, *c* 1.22). The Br atoms are removed as easily as they are introduced; by the anal. method of Hudson and Johnson (treatment with 50% $AgNO_3$ in the cold) up to 97% of the Br can be detected. From all previous experience it may be concluded that 1 of the Br atoms is on the 1-C atom and therefore very labile, but that there should be a 2nd labile Br atom and correspondingly a 2nd strongly reactive HO group in a hexose is without previous analogy. It will therefore be of special interest to det. the position of this 2nd Br atom. C. A. R.

Stereoisomeric polyhydroxycycloalkanes. II. Stereoisomeric pyrogallitols. Hans Lindemann and Adriaan de Lange. *Ann.* **483**, 31-43(1930); cf. *C. A.* **24**, 1629.—Catalytic reduction of 1,2,3-$C_6H_3(OH)_3$ gives a small amt. of cyclohexane and cyclohexanol, a mixt. of *cis*- and *trans*-cyclohexane-1,2-diols (*diphenylurethans*, m. 185° and 212°, resp.), and a mixt. of α (I), β (II) and γ (III)-cyclohexane-1,2,3-triols. I, m. 108°; tribenzoate, m. 142°; *tri*-(*l-menthylurethan*), m. 120°, then solidifies and m. 213°, $[\alpha]_D^{23}$ −59.6° in C_5H_5N. II, m. 124-5°; tribenzoate, m. 184°. III, m. 148°; *tribenzoate*, m. 142°; *tri*-(*l-menthylurethan*), m. 130° and then 208°, $[\alpha]_D^{25}$ −56.2° in C_6H_6. III is identical with that (m. 145°) described by Senderens and Aboulenc (*C. A.* **16**, 2133) but their so-called triol, m. 95°, is a cyclohexane-1,2-diol. The triol, m. 67°, of Sabatier and Mailhe (*Compt. rend.* **146**, 1196(1908)) could not be prepd. Hydrolysis of the above benzoates gives the appropriate triol, which can be rebenzoylated to the corresponding ester; no inversion occurs during hydrolysis. The above triols are the 3 theoretically possible cyclohexane-1,2,3-triols. C. J. West

Preparation of unsaturated ethers from acetals. Akop Johannissian and Elizabeth Akunian. *Bull. univ. état R. S. S.-Arménie*, No. 5, 245-9(in German 249-51)(1930).—(1) *Cyclohexanone di-Et acetal* (I) (12 g.) and 0.04 g. *p-MeC*$_6$*H*$_4$*SO*$_3$*H* (II), in an oil bath and distd., yielded 7.6 g., or 87.3%, of *1-ethoxycyclohexene*, b_{16} 47-8°.

(2) I (20 g.), 4 mols. BuOH and 0.05 g. II yielded 88.8% of *1-butoxycyclohexene*, b_{10} 80–1°. (3) *1-Hexoxycyclohexene* (90% from I, hexanol and II), b_7 108–9°. (4) I, heated in an air bath at 775 mm., distd. at 48–50° and 10 mm., yielded 85.7% of 1-ethoxycyclohexene, b_{10} 48–50°. (5) I, heated at 685 mm., gave 90.9% of 1-hexoxycyclohexene, b_{7-9} 108–10°. (6) *Cyclohexanedione di-Et acetal* (10 g.) heated alone at 677 mm., yielded an oily substance, b_{78} 147.2–7.5°, which largely crystd. upon cooling. The crystals proved to be *1,4-diethoxycyclohexa-1,4-diene*. B. S. Levine

***p*-Toluenesulfonic acid as a catalyzer in the preparation of acetal derivatives.** Akop Johannissian and Elizabeth Akunian. *Bull. univ. état R. S. S. Arménie*, No. 5, 235–41 (in German 242–4) (1930).—J. and A. undertook to prove that *o*-$MeC_6H_4SO_3H$ (I) as a catalyzer in the prepn. of acetals is superior to HCl, H_2SO_4, NH_4Cl, $FeCl_3$, etc. (1) Cyclohexanone (40 g.), 1.25 mols. $HC(OEt)_3$ (II), 4 mols. abs. alc. and 4 cc. 0.01% soln. of the catalytic agent (I) in abs. alc., boiled 10 min., cooled with running water, neutralized with KOEt, freed from the HCO_2Et and alc. by distn. and fractionated under 13 mm., gave 96% *cyclohexanone di-Et acetal* (III), b_{13} 75–6°. (2) *p*-$MeOC_6H_4CHO$, I and II, refluxed 3 min., gave 88.1% of *anisaldehyde di-Et acetal*, b_{14} 130–2°. (3) Cyclohexanedione, I and II, refluxed 10 min., gave 96.8% *1,4-cyclohexanedione bis(di. acetal)*. (4) III (20 g.), 4 mols. BuOH and 0.04 g. solid I, heated in an oil bath, gave 87.6% *cyclohexanone di-Bu acetal*, b_{10} 118–20°. (5) III (10 g.), 4 mols. *hexanol* 0.04 g. cryst. II, heated in an oil bath, gave 91% of *cyclohexanone dihexyl acetal*, b. 162° (6) *p*-$MeOC_6H_4CH(OEt)_2$ (21 g.), 4 mols. BuOH and 0.05 g. cryst. I gave 82% of *anisaldehyde di-Bu acetal*, b. 168–70°. B. S. Levine

Carbon rings. XV. Preparation and some physical constants of various carbon rings containing up to 32 carbon atoms. L. Ruzicka, M. Stoll, H. W. Huyser and H. A. Boekenoogen. *Helv. Chim. Acta* **13**, 1152-85 (1930); cf. *C. A.* **23**, 1411. The hitherto unprepd. ring compds. contg. 24, 26, 28 and 32 C atoms were prepd. by reduction of the corresponding diketones. Further details are given for the prepn. of various cyclic ketones by the action of heat on yttrium polymethylenedicarboxylates, the salts decompg. to give the mono- and also the diketones. Phys. consts., such as p., m. p., d., mol. refraction and mol. vol., are given for these new compds. and also for a large no. of previously prepd. cyclic hydrocarbons (C_5-C_{32}, C_{19} and C_{30}) and their derivs. In general, the m. ps. of the hydrocarbons and ketones oscillate up to about C_{14}, reach a max. at C_{18-19}, then decrease to about C_{28} and finally rise again. Series relationships are discussed from the standpoint of d., mol. refraction and mol. vol. The following new compds. are described: *Cyclotetracosane*, m. 46–7°, $b_{0.6}$ 222–8°; *cyclotetracosanone*, m. 35–6°, $b_{0.4}$ 233–8°; *cyclotetracosane-1,13-dione*, m. 64–5°, $b_{0.25}$ 216°; *cyclohexacosanone*, m. 41–2°, $b_{0.5}$ 218–9°, d_4^{20} 0.846; *cyclohexacosanone*, m. 41–2°, $b_{0.1}$ 208–12°; *hexacosane-1,14-dione*, m. 68–9°, $b_{0.1}$ 235°, d_4^{20} 0.912; *cycloöctacosane*, m. 47–8°, 213–4°, d_4^{20} 0.846; *cyclooctacosanone*, m. 44–5°, $b_{0.25}$ 210°; *cycloöctacosane-1,15-dione*, m. 72–3°, $b_{0.2}$ 238–41°, d_4^{20} 0.919; and *cyclodotriacontane-1,17-dione*, m. 77–8°, 258–62°. A. Wibaut

nucleus.

Two cases of substitution phenomena are to be differentiated, viz., [illegible] tion, in which a H atom of the nucleus is replaced directly by a new substituent *indirect* substitution, which occurs in the presence of the groupings OH, NH_2, NHX and Me. Indirect substitution takes place much more readily, always takes place in the *o*- and *p*-positions and may be accompanied by a displacement of a group, already present, by the entering substituent. In these displacement phenomena there exists a definite order, namely CO_2H, CHO, SO_3H, I (COMe, COPh, OMe, AsO_2H_2, PO_3H_2), Br, Cl, NO_2, in which an atom or group is able to displace the ones preceding. Blanksma and his co-workers have often made use of these displacement phenomena. The several cases are, however, scattered throughout the literature; they have now been collected and arranged systematically in order to demonstrate that this method affords a general way for detg. the constitution of aromatic compds. C. F. van Duin

Conjugated systems. VI. Preparation of the geometric isomers of methylstyrylcarbinol and of phenylbutadiene. Irving E. Muskat and Margaret Herrman. *J. Am. Chem. Soc.* **53**, 252–60 (1931); cf. *C. A.* **24**, 5716.—The reaction product of PhCH:CHCHO and MeMgBr, prepd. according to M. and Ludeman (*C. A.* 24, 347) and decompd. with 10% acid, the decompn. mixt. extd. with Et_2O and carefully freed from acid, gives *trans-methylstyrylcarbinol* (I), $b_{0.5}$ 116.5°, b_5 117.5°, $b_{7.5}$ 123°, n_D^{21} 1.5550; its structure was proved by ozonization. I is stable for many months and is dehydrated

only by very strong dehydrating agents. H_2O may be used in the above decompn., but the yield is much less; 30% H_2SO_4 may also be used. If the acid is not carefully removed there results a mixt. of I and the ordinary *cis*-form (II). Decompn. with 50% H_2SO_4 gives some *trans*-phenylbutadiene (III), b_{11} 76°, which also results from the chloride of I and C_5H_5N. II readily loses H_2O to give the *cis*-phenylbutadiene (IV). The structures of III and IV have been confirmed by the relative rates of catalytic hydrogenation, IV being reduced more rapidly. IV, on standing overnight with a trace of acid, gives III on distg.; acid rearranges I into II. IV is also oxidized more rapidly than III. The structure of I was likewise confirmed by catalytic reduction, II being reduced more rapidly. **VII. Chemical reactions of the geometric isomers of methylstyrylcarbinol.** *Ibid* 260–71.—I and PhCNO give *phenylurethan*, m. 94°; no such deriv. of II could be prepd. I yields an *acetate*, b_{15} 141–4°, by boiling with Ac_2O for 6 hrs.; II, under the same conditions, gave a dimer of IV. I gives a *chloride*, b_6 104°; that from II b_6 108°. The *trans*-chloride with 10% AcONa gives a mixt. of the acetate and the condensation product V; with Ag_2O in H_2O there results III and its polymer; C_5H_5N gives III. The *cis*-chloride with C_5H_5N gives about 40% of IV, the remainder being the dimer, b_{10} 205°. The *trans*-chloride and 5% NaOH, shaken for 24 hrs., give III; the *cis*-chloride gives a very small yield of IV, the greater portion being the dimer. Heating I at 180° gives a *condensation product*, $C_{20}H_{22}O$ (V), b_6 200°; *tetrabromide*, m. 179°. O_3 gives 76% BzH. Attempts to prep. a Br addn. compd. from I or II failed, decomposition occurring with the elimination of H_2O and the formation of phenylbutadiene tetrabromide. Catalytic reduction of I and II gave $PhCH_2CH_2CH(OH)Me$, b_6 105°; the relative rates are given as curves, II being reduced more rapidly. The same is true for the oxidation with BzO_2H; the rate of oxidation is best expressed by an equation for order reaction. The *oxides* of I and II b_4 118° and $b_{3.5}$ 117°, resp.; the oxide from I, heated with 2 *N* H_2SO_4, gives a condensation product, b_4 200°; dry HCl in Et_2O does not open the oxide ring nor does NH_3 in EtOH; it may be that the oxide had rearranged to a ketone. C. J. West

Methods of reaction of phosphorus pentachloride. C. Harnist. *Ber.* **63B**, 2367(1930); cf. Bergmann and Bondi, *C. A.* **24**, 4024.—The addn. of PCl_5 to $Ph_2C{:}CH_2$, styrene and indene was discovered in Thiele's lab. in 1910 (Harnist, *Diss. Strassburg* **1910**; Bulle, *ibid* **1911/12**). C. A. R.

The oxidation of organic iodine compounds by means of organic peracids (preliminary paper). J. Böeseken and G. C. C. C. Schneider. *Proc. Acad. Sci. Amsterdam* **33**, 827–9(1930).—PhI, *o*-$C_6H_4I_2$, the I derivs. of PhMe, BzOH, $PhSO_3H$ and PhNO and $(CHI)_2$ when treated with AcO_2H yield the corresponding iodoso compds., usually as acetates. With BzO_2H the iodo (iodoxy) compds. were obtained except with ICH_2CO_2H and *p*-$IC_6H_4SO_2H$ which give iodoso compds. believed to be internal salts without ring structure. The iodosoacetates treated with BzO_2H give the iodoxy compd. *Iodosobenzenesulphonic acid*, m. 156.4° (decompn.), is formed by treating 5 g. *p*-$IC_6H_4SO_2H$ with 10 cc. 13% AcO_2H or with 90 g. of a 6.7% BzO_2H in $CHCl_3$. Other new compds. prepd. are *o-diiodoxybenzene* and *diiodoxyethylene*. J. E. A.

Decomposition of phenyl dichloroiodide. III. Criticism of results obtained by Guglialmelli Ruiz, Chanussot and Hermitte. Enrique V. Zappi and Venancio Deulofeu. *Anales asocn. quím. Argentina* **18**, 124–32(1930); cf. *C. A.* **24**, 3226.
E. M. Symmes

The action of sodium methylate on some derivatives of *o*-dichlorobenzene. G. M. Kraay. *Rec. trav. chim.* **49**, 1082–92(1930).—The compds. investigated were prepd. as follows: *1,2,4-dichloronitrobenzene* (I) according to Reiding (*Rec. trav. chim.* **23**, 364(1904)), m. 43°; *3,4-dichloroaniline* (II) by reduction of I with Fe and acidulated water; *1,2,4-dichlorofluorobenzene* (III) from II in the way already described (Kraay, *C. A.* **23**, 4690), a pure prepn., however, not being obtained; *1,2,4-trichlorobenzene* (IV) from II by the Sandmeyer reaction, m. 17°; *1,2,4-dichlorobromobenzene* (V) from II by the Sandmeyer reaction in 80% yield, m. 24.4–4.8°; *1,2,4-dichloroiodobenzene* (VI) from II by the action of KI on the diazo compd. m. 30.5°; *3,4-dichlorobenzenesulfonic acid* (VII), according to van der Linden (*Rec. trav. chim.* **30**, 332(1911); cf. *C. A.* **6**, 1293); the Na salt crystallizes without H_2O; *3,4-dichlorobenzonitrile* (VIII) from II by the Sandmeyer reaction, m. 71.8–2.1°; this nitrile may be saponif. easily with 20% alc. KOH, *3,4-dichlorophenol* (IX) according to Holleman's method (*C. A.* **12**, 1542); *3,4-dichloronitrobenzene* (X) according to Holleman's method (*Rec. trav. chim.* **31**, 228(1912); cf. *C. A.* **7**, 1963), $b_{745.5}$ 206.3–8.8°; *1,2,4-dichloronitrosobenzene* (XI) by oxidation of the corresponding $Cl_2C_6H_3NHOH$ (Lapworth and Pearson, *C. A.* **15**, 2838; Haworth and Lapworth, *C. A.* **15**, 2838, m. 75°) with the calcd. amount of CrO_3, m. 88°. The 3,4-$Cl_2C_6H_3NHOH$ is oxidized in alc. by the air to *3,4,3',4'-tetrachloroazoxybenzene*,

m. 139–9.5°; *3,4-dichlorobenzophenone* (XII) according to the method of Böeseken (*C. A.* **2**, 1132), m. 102–3°; *3,4-dichlorobenzaldehyde* (XIII) by first chlorinating X at its b. p. to $Cl_2C_6H_3CHCl_2$ and then sapong. the latter compd. with boiling water in the presence of $CaCO_3$ or with fuming H_2SO_4 (Erdmann and Schwechten, *Ber.* **18**, 470(1885), Ger. pat. 32,238); the aldehyde, purified by means of the bisulfite compd., m. 42–2.6°. With the Cannizarro reaction XIII gives *3,4-dichlorobenzoic acid*, (XIV) m. 208–9°, and *3,4-dichlorobenzyl alc.*, m. 38°. XIV, however, is obtained in a purer state and with the m. p. mentioned above, by sapon. of VIII. With NaOMe these compds. show the following reactions: I is converted into 2,4-$Cl_2C_6H_3OMe$ (de Mooy, *Rec. trav. chim.* **31**, 230(1912)); II is resinified completely; III gives 3,4-$Cl_2C_6H_3OMe$ and by prolonged heating 3,4-$Cl_2C_6H_3OH$, m. 65–6°; IV gives 2,5-$Cl_2C_6H_3OH$ (Holleman, *C. A.* **10**, 1508), m. 57°; V yields *2-chloro-5-bromophenol*, m. 57°, which was synthesized from 2,5-$ClBrC_6H_3NO_2$ by reduction and diazotization in the usual way; VI was converted into a mixt. of 3,4-$Cl_2C_6H_3OH$ and *2-chloro-5-iodophenol*, m. 56°; the latter compd. was again synthesized in the following way: 4,3-$Cl(O_2N)C_6H_3NH_2$ was converted into *1-chloro-4-iodo-2-nitrobenzene*, m. 74.5°, by the Sandmeyer reaction, the nitro compd. being again reduced by $TiCl_3$ to the amino compd., *2-chloro-5-iodoaniline*, m. 61.6°, which was converted into *2-chloro-5-iodophenol*, m. 56°, in the usual way. VII gives $Cl(HO)C_6H_3SO_3H$, which on nitration is converted into 2,4,6-$Cl(O_2N)_2C_6H_2OH$, m. 110–1°, and thus must be 3,4-$Cl(HO)C_6H_3SO_3H$; VIII is sapond., IX remains unchanged, while X gives a liquid phenolic substance, which was not identified, and *2-chloro-5-methylphenol*, m. 46°, which was prepd. also from 2,5-$ClMeC_6H_3NH_2$ in the usual way. XI is converted into the $(3,4\text{-}Cl_2C_6H_3)_2N_2O$, m. 139°, mentioned above, while XII, XIII and XIV gave a reaction with the elimination of Cl, it being, however, impossible to isolate the compds. formed. In order to get some idea of the relative velocities of the reactions of these compds. with NaOMe, 5 millimols. were heated with 2 equivs. of 0.5 *N* NaOMe during 3 hrs. at the b. p. of aniline, 183°, then the MeOH was evapd. on the water bath and the halogen detd. after acidulation with HNO, the following results being obtained: III, 83% F, 4% Cl; IV, 72% Cl; V, 83% Cl and a small amount of Br; VI, 94% Cl + I; VII, 79% Cl; X, 3% Cl; XIV, 20% Cl, and IX, 0%. C. F. VAN DUIN

Action of iodine and of halogen derivatives on *aci*-nitro-alkali compounds. COSTIN D. NENITZESCU AND DIMITRIE A. ISĂCESCU. *Ber.* **63B**, 2484–96(1930).—$(C_6H_4)_2C$ N(:O)OK (I) and PhCH:N(:O)ONa (II) lose their alkali to I and form the compds. $(C_6H_4)_2C(NO_2)C(NO_2)(C_6H_4)_2$ (III) and $PhCH(NO_2)CH(NO_2)Ph$ (IV) (*C. A.* **24**, 1094). It has now been found that under somewhat different conditions I, II and other *aci* nitro-alkali compds. RR'C:N(:O)ONa give with I the iodonitro compds. RR'C(NO₂)I which would normally be expected. These are generally stable enough at room temp to permit of their analysis; on standing or heating they lose I. They were of special interest as possibly being intermediate products in the formation of the compds. of type III and IV. In fact, $(C_6H_4)_2C(NO_2)I$ (V) with I and $PhCH(NO_2)I$ (VI) with II gave III and IV, resp., but this reaction could not be brought about with any of the other *aci*-nitro-alkali and iodonitro compds. V, heated in solvents, gives III and I almost quantitatively with a rapidity depending on the b. p. of the solvent (in a few min in AcOH, in about 2 hrs. in MeOH). The reaction can hardly be interpreted as being other than a dissocn. into radicals which then polymerize, the great tendency of fluorene radicals to polymerize making the dissocn. non-reversible. I, boiled with alc. MeI $PhCH_2Cl$, EtBr or $ClCH_2CO_2Et$, gives the K halide and more than 80% $(C_6H_4)_2C$ NOH (VII), the org. halide being converted into the aldehyde; probably an unstable nitronic ester is an intermediate product: $I + XCH_2R \longrightarrow [(C_6H_4)_2C:N(:O)OCH_2R] \longrightarrow$ VII + OHCR. Secondary halides react in the same way, giving VII and ketones Me_2CHBr and Me_2CHI smoothly yielded Me_2CO, the iodide also giving a little III. Bromocyclohexane did not react even after 8 hrs. boiling, while $BrCH(CO_2Et)_2$ gave VII and a little III. The tertiary Me_3CBr reacted readily in boiling alc., giving $Me_2C:CH_2$, III and VII, whereas, by analogy with the thermal decompn. of other esters, it was expected that there would be formed $(C_6H_4)_2C:N(:O)OH$ (VIII), which under the exptl. conditions would rearrange into the true $(C_6H_4)_2CHNO_3$ (IX). As no indications of the presence of other than the above compds. was obtained, a direct comparison was made of the III obtained electrolytically with the compd. described in the literature as the true IX and it was found that the 2 are identical. As the structure of III has been established with certainty, the supposed IX must also have this structure, a view in harmony with its phys. properties. The peculiar conversion of VIII into III is represented by the scheme 3 VIII $\longrightarrow$ [3 IX] $\longrightarrow$ 2 III + VII + H_2O, which is in excellent agreement with the results of a semi-quant. expt. which was carried out. Attempts to prep

IX by rearrangement of VIII under mild conditions or from V with HI were unsuccessful, the latter reaction giving pure VIII. The formation of $Me_2C:CH_2$ from I and Me_3CBr probably takes place through the nitronic ester: $(C_6H_4)_2C:N(:O)OCMe_3 \longrightarrow$ VIII + $CH_2:CMe_2$; if the reaction is carried out at room temp. instead of in boiling alc., VIII is obtained in good yield. $PhCH_2CMe_2Br$ and Ph_3CCl with I both gave III and VII. Picryl chloride and $EtCHBrCO_2Et$ did not react even after long boiling. II and its *p*-Br deriv. react much less readily than the fluorene compds. with MeI. The only definite products which could be identified were PhCH:CHPh and $(p\text{-}BrC_6H_4CH:)_2$. With Me_3CBr, II gives $PhNHNO_2$. *9-Iodo-9-nitrofluorene* (V), yellow, m. 86°, decomps. violently a few degrees higher. *Aryliodonitromethanes: Ph* (VI), yellow oil; *p-tolyl*, yellow oil; *p-chlorophenyl*, lemon-yellow, m. 30°, decomps. 173°; *p-bromophenyl*, yellow, m. 35°, becomes colored 135°, decomps. 165°; *p-nitrophenyl*, m. 90°, decomps. 150°, quickly becomes colored on standing; *α-naphthyl*, m. 74°, decomps. 110–35°; *β-naphthyl*, m. 60°, decomps. 105°; *diphenyl*, yellow, m. 62°, decomps. 64°, decomps. suddenly within 0.5 hr. after it has been prepd. *Iodonitromethane*, from $MeNO_2$ in 2 *N* NaOH with I-KI at 0°, yellow, strongly lacrimatory oil which cannot be distd. and slowly deposits I. C. A. R.

Firmness of attachment of organic residues. VII. JULIUS V. BRAUN AND AUGUST FRIEDSAM. *Ber.* **63B**, 2407–13(1930); cf. *C. A.* **22**, 381.—It was shown in Paper V that introduction of a halogen atom into a $PhCH_2$ residue increases the firmness of attachment of the latter to N in the order I > Br > Cl as regards the nature of the halogen and *o* > *m* > *p* as regards its position. $FC_6H_4CH_2$ might therefore have been expected to be attached less firmly than $ClC_6H_4CH_2$ but more firmly than $PhCH_2$. The chemistry of it shows so many peculiarities, however, that it was possible that it would prove an exception to the rule, and such is the case; the introduction of an *o*-, *m*- or *p*-F atom into $PhCH_2$ has practically no effect on the firmness of attachment of the $PhCH_2$ residue, as shown by the action of BrCN on the following compds.: $PhCH_2NMeCH_2C_6H_4F(p)$ (I), $p\text{-}MeC_6H_4CH_2NMeCH_2C_6H_4F(p)$ (II), $p\text{-}MeC_6H_4CH_2NEtCH_2C_6H_4F(p)$ (III), $p\text{-}ClC_6H_4CH_2NMeCH_2C_6H_4F(p)$ (IV), $PhCH_2NMeCH_2C_6H_4F(o)$ (V), $p\text{-}FC_6H_4CH_2NMeCH_2C_6H_4F(o)$ (VI) and $PhCH_2SCH_2C_6H_4F(m)$ (VII). These were obtained by treating the $FC_6H_4CH_2Br$ (prepd. from the $MeC_6H_4NH_2$ through the MeC_6H_4F by bromination of the side chain) with 3–4 mols. of a secondary amine 1 day at room temp. and 1 hr. at 60°. The yields were about 40%. The reaction with BrCN was carried out by slowly adding 1 mol. BrCN to the cold amine, heating the clear mixt. 0.5 hr. on the H_2O bath, adding Et_2O (which ppts. the addn. product with the original base of the bromide split off by the BrCN), shaking the Et_2O out with dil. HCl, treating the distillate (bromide and cyanoamide) 12 hrs. with an excess of Me_3N and adding Et_2O. The bromide is thereby pptd. as the quaternary salt, $RNMe_3Br$, and the cyanoamide is isolated by shaking the alc.-Et_2O filtrate with H_2O and distg. II, III and IV gave homogeneous products, I, V, VI and VII gave mixts. of 2 bromides and 2 cyanoamides. III was used as a check on II to show, as had been found before, that a 3rd substituent on a N contg. 2 aromatic groups has no influence on the course of the reaction if it is itself a firmly attached residue. *Benzyl-p-fluorobenzylmethylamine* (I), from $p\text{-}FC_6H_4CH_2Br$ and $PhCH_2NHMe$, b_{18} 168–70° (*HCl salt*, slightly hygroscopic, m. 153–6°; *picrate*, m. 105°; *methiodide*, m. 221°), yields with BrCN almost equimol. mixts. of $PhCH_2Br$ + $FC_6H_4CH_2Br$, isolated as $RNMe_3Br$ (the pure salt *p* $FC_6H_4CH_2NMe_3Br$, prepd. for comparison, m. 228–9°), and $PhCH_2NMeCN$ + FC_6H_4NMeCN. *p-Methylbenzyl-p-fluorobenzylmethylamine* (II), b_{10} 166–8° (*HCl salt*, very hygroscopic, m. 183°; *picrate*, m. 110–2°; *methiodide*, m. 216–7°), yields with BrCN almost pure $MeC_6H_4CH_2Br$ and the *cyanoamide*, $FC_6H_4CH_2NMeCN$, b_{10} 148–54°. The reaction was even more sharp cut with *p-methylbenzyl-p-fluorobenzylethylamine* (III), prepd. from *p methylbenzylethylamine*, b_{10} 98–9° (*HCl salt*, hygroscopic, m. 189°; *picrate*, m. 89°); the III, b_{10} 175° (HCl salt and picrate, oily; *methiodide*, m. 122–5°), gives with BrCN $MeC_6H_4CH_2Br$ and the *cyanoamide*, $p\text{-}FC_6H_4CH_2NEtCN$, b_{10} 155°. *Benzyl-p methylbenzylethylamine*, b_{11} 82°, gives pure $MeC_6H_4CH_2Br$ and the *cyanoamide*, $PhCH_2NEtCN$, b_{12} 160°. *p-Chlorobenzyl-p-fluorobenzylmethylamine* (IV), b_{10} 182–4° (*HCl salt*, m. 160–1°; *picrate*, m. 129°; *methiodide*, m. 210–2°), gives $FC_6H_4CH_2Br$ and the *cyanoamide*, $p\text{-}ClC_6H_4CH_2NMeCN$, b_{10} 166°. *Benzyl-o-fluorobenzylmethylamine* (V), b_{11} 158–60° (*HCl salt*, m. 189°; *picrate*, m. 99°; *methiodide*, m. 213°), gives with BrCN a mixt. of bromides and cyanides which, however, are not equimol., the $PhCH_2Br$ and the $p\text{-}FC_6H_4CH_2NMeCN$ predominating; the pure $o\text{-}FC_6H_4CH_2NMe_2Br$ m. 225°. *p-Fluorobenzyl-o-fluorobenzylmethylamine* (VI) (from *p-fluorobenzylmethylamine*, b_{14} 80–2°; *HCl salt*, m. 199°; *picrate*, m. 131°), b_{12} 164–6° (*HCl salt*, very hygroscopic, m. 130°; *picrate*, m. 142°; *methiodide*, m. 230°), gives a mixt. of *o*- and *p*-$FC_6H_4CH_2Br$ and of *o*- and *p*-$FC_6H_4CH_2NMeCN$, the latter of which is hydrolyzed by concd. HCl at 130°

to *o*- and *p*-$FC_6H_4CH_2NHMe$; the *o-fluorobenzylmethylamine* b_{12} 73° (*HCl salt*, m. 160°, *picrate*, m. 139–40°. *Benzyl m-fluorobenzyl sulfide* (VII), from $PhCH_2SH$, Na and *m*-$FC_6H_4CH_2Br$ in alc., faintly yellow, $b_{0.3}$ 140–2°, gives with BrCN a mixt. of $PhCH_2Br$ and $FC_6H_4CH_2Br$ and of PhCHSCN and $FC_6H_4CH_2SCN$. Pure $FC_6H_4CH_2NMe_2Br$ m. 231°.

C. A. R.

Picramic acid. E. Clayton. *J. Soc. Dyers Colourists* **46**, 365–7(1930).—A 90% yield is obtained by the following method: 10 g. com. picric acid in 250 cc. hot H_2O is neutralized with 40 cc. 5% NaOH and cooled to 50°. Fifty cc. of $Na_2S_2O_4$ is added with stirring. Fine crystals settle out and are filtered after the soln. is cool.

Milton Harris

The behavior of phenylenediamines with aromatic nitro derivatives. G. B. Crippa with G. Bellani and A. Marubini. *Gazz. chim. ital.* **60**, 644–7(1930).—$PhNO_2$ (I) reacts with phenylenediamines in 2 different ways, *viz.*, to form condensation products and as an oxidizing agent. In earlier expts. of C. (cf. *C. A.* **21**, 1809) it was shown that in the reaction of I and *p*-$C_6H_4(NH_2)_2$ (II) a large quantity of an unidentified black substance (III) is formed. It was regarded as an oxidation product of the polynuclear oxidation of II, and therefore analogous to aniline black (IV), but since it was too complex to identify, it was decided to establish its identity through some intermediate phase in the same way that numerous investigators have studied the intermediate products leading to IV. Judged by other cases of oxidation of II, the intermediate oxidation products should be 2,5,2′,5′-tetraaminodiphenyl-*p*-azophenylene (V). Therefore I and II were condensed as before, but the boiling was interrupted at a much earlier point than before, the reaction mixt. was steam-distd. and the distillate was let stand several months in a closed vessel. V sepd. and m. 249° (much higher than previously recorded, *e. g.*, Bandroski, 230–1°, Erdmann, 242–3°). However, tetraacetyldiaminodiphenyl-*p*-azophenylene m. 293–4°, which agrees with the earlier literature. It was possible, however, that oxidation had led to V only during the long standing and that it was not a normal intermediate product of the reaction of I and II at the higher temp. and shorter time. Further expts. showed that the long standing was not a factor, for II (5 g.), I (40 g.) and anhyd. Na_2CO_3 (2 g.) boiled 2 hrs., filtered, extd. with EtOH, and the EtOH partially eliminated, pptd. V. V (2 g.) and I (50 cc.), boiled, steam-distd., and the residue extd. with Et_2O, left a residue of III, which shows that the oxidation of II by I leads first to V and thence to III. *o*-$C_6H_4(NH_2)_2$ (VI) condenses with I to form phenylbenzotriazole and *o*-aminoazobenzene (cf. C. and Castelli, *C. A.* **22**, 418). This reaction was studied further to ascertain whether the 3 isomeric nitrotoluenes are reactive enough to react like I in such a condensation. It was found that only *m*-$MeC_6H_4NO_2$ (VII) condenses with VI. VI (10 g.), anhyd. Na_2CO_3 (2 g.) and VII (80 g.), boiled 20 hrs., steam-distd. and the distillate fractionally crystd., yields 2 products (1) 2-*N*-(*m-tolyl*)-*1,2,3-benzotriazole*, $C_6H_4<\begin{matrix}N\\|\\N\end{matrix}>NC_6H_4Me$-*m* (VIII), according to the reaction.

VI + VII ⟶ VIII + $2H_2O$, and the secondary product *m-tolylazo-o-aminobenzene*, *o*-$H_2NC_6H_4N{:}NC_6H_4Me$ (IX), formed thus: VI + VII − O ⟶ IX. Recrystd. from ligroin, VIII m. 99°. To establish its constitution and that of IX they were prepd. by another method. *m*-MeC_6H_4NO was condensed with benzoyl-*o*-phenylenediamine (cf. Witt, *C. A.* **7**, 83), and *m*-tolylazo-*o*-(benzoylamino)benzene which is obtained forms IX on sapon. IX recrystd. from ligroin is pomegranate-red and m. 81°. According to IX the general method of Zincke (*Ber.* **18**, 3136) it forms VIII. The behavior of *m*-$C_6H_4(NH_2)_2$ with I was also studied. Unlike its isomers II and VI, no condensation took place, and after the same treatment as in the other cases azobenzene was the only product which was formed by the reduction of I.

C. C. Davis

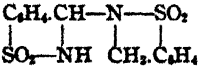
Catalytic effect of magnesium alcoholates on the reaction of Grignard reagents with carbon dioxide. Corliss R. Kinney and M. L. Mayhue. *J. Am. Chem. Soc.* **53**, 190–9(1931).—Curves are given showing the depression in yield of the reaction of several Grignard reagents with CO_2 caused by the addn. of relatively small quantities of the alcs. corresponding to the reagents. Reactions are given which indicate an equil. relationship between Ph_3CMgCl and Ph_3C. Cleavage of Ph_4C with MgI was not successful. The yield of Ph_3CCO_2H from Ph_3CMgCl and CO_2 is decreased from 75% to 63.5% by the addn. of 0.8 mol. % Ph_3COH before the prepn. of the Grignard reagent; to 55% by 3.1 mols. %; to 33.2 by 6 mols. %; to 16.6 by 12.3 mols. % and to 0 by 15.3 mols. %. The yield of $PhCH_2CO_2H$ from $PhCH_2MgCl$ is decreased from 84.5% to 74.3, 65.8 and 46.3%, resp., by the addn. of 2, 10 and 20 mols. % of $PhCH_2OH$. The

yield of BzOH from PhMgBr is decreased from 72.1 to 58.6, 45.1, 35.9 and 29.1%, resp., by the addn. of 0.5, 2, 6 and 7 mols. % of PhOH. The yield of $BuCO_2H$ was decreased from 78.4 to 63.5, 50 and 26.2%, resp., by the addn. of 2.43, 9.46 and 24.3 mols. % of BuOH. C. J. WEST

Phenylmagnesium fluoride. HENRY GILMAN AND LLOYD L. HECK. *J. Am. Chem. Soc.* **53**, 377–8(1931).—PhMgF was formed from PhF and Mg–Cu alloy in Et_2O after standing 18 months at room temp. No reaction had occurred in the first 6 months. C. J. WEST

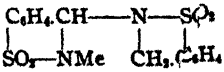
Preparation of aromatic mercuric chlorides from aromatic diazonium chlorides. ROBERT E. MCCLURE AND ALEXANDER LOWY. *J. Am. Chem. Soc.* **53**, 319–21(1931).—Aromatic mercuric chlorides are obtained by stirring a mixt. of RN_2Cl and Hg at about 5°. In this way the following compds. were prepd.: PhHgCl, 45%; *p*-MeC_6H_4HgCl, 52%; *o*-MeC_6H_4HgCl, 72%; 2,5-$Me_2C_6H_3HgCl$, 64%; α-$C_{10}H_7HgCl$, 20%. PhN_2Cl and Black pptd. Hg give 20% PhHgCl. C. J. WEST

Nitrogenous arsenical derivatives. S. BERLINGOZZI AND M. LIGUORI. *Ann. chim. applicata* **20**, 494–500(1930).—A no. of complex derivs. of $ClN{:}NC_6H_4AsO_3H_2$ have been prepd. so as to make a systematic study of the relation between chem. constitution and physiol. action. *1,3-Dihydroxybenzene-6-azo-p-benzenearsonic acid* was prepd. by diazotizing *p*-$H_2NC_6H_4AsO_3H_2$ (I) and adding resorcinol soln. It is slightly sol. in the common solvents, so is purified by means of its Na salt; it m. above 250°. *1,3-Dihydroxybenzene-4,6-bisazo-p-benzenearsonic acid* (II), $(HO)_2C_6H_2(N{:}NC_6H_4AsO_3H_2)_2$, is prepd. by diazotizing I and coupling it with another mole of I. It is a red-brown cryst. solid, does not decomp. below 250°. *1,3-Dihydroxybenzene-6-α-naphthaleneazo-4-azo-p-benzenearsonic acid* (III), prepd. by combining diazotized α-$C_{10}H_7NH_2$ with II; is a dark red solid, decomps. above 250°. *1,3-Dihydroxybenzene-2,4,6-triazo-p-benzenearsonic acid*, is prepd. by combining $ClN{:}NC_6H_4AsO_3H_2$ with II, or, preferably, with resorcinol. When dry it is a black powder. *1-Amino-3-hydroxybenzene-6-α-phenylazo-8-azo-4-azo-p-benzenearsonic acid* is prepd. by combining diazotized α-phenylaminoquinoline with 4-[4,2-$H_2N(HO)C_6H_3N{:}N$]$C_6H_4AsO_3H_2$ in alk. soln. The product is an orange-red powder, darkens above 180°, decomps. above 250°. Similarly, $C_6H_3N(NCl)_2$, made by diazotizing benzidine, may be combined with 4-[4,3-H_2N-$HO(C_6H_3N{:}N$]$C_6H_4AsO_3H_2$ and also with the 4,3-$(HO)_2$ compd. The first product is a dark red, the latter a chocolate-brown powder, stable below 250°. A. W. C.



Reaction between dichloroarsines and secondary aromatic amines. C. S. GIBSON. *J. Soc. Chem. Soc.* **53**, 376–7(1931).—G. calls attention to work apparently overlooked by Lewis and Stiegler (*C. A.* **24**, 5719). C. J. WEST

Reaction of mercury organic compounds with tin salts as a method of preparing an organic compounds. A. N. NESMEYANOV AND K. A. KOCHESHKOV. *Ber.* **63B**, 2204–14(1930).—The reaction of R_2Hg and RHgX with Sn salts has been studied and found to vary greatly with the solvent, the org. compd., and the inorg. compd. and their solv. In anhyd. Me_2CO, Ph_2Hg, $(PhCH_2)_2Hg$, $(MeC_6H_4)_2Hg$, $(\alpha\text{-}C_{10}H_7)_2Hg$ (I) and $(C_6H_{11})_2Hg$ react with $SnCl_2$ or $SnBr_2$ thus: $R_2Hg + SnX_2 = R_2SnX_2 + Hg$. In alc. the reaction is all or partly $R_2Hg + SnX_2 + EtOH = 2RH + Hg + (EtO)_2SnX_2$. I reacts thus even in Me_2CO. All aromatic compds. react rapidly. Et_2Hg reacts only after hrs. of boiling, the reaction $Et_2SnX_2 + Et_2Hg = Et_2SnX + EtHgX$ also taking place. Freshly prepd. $(PhCH_2)_2Hg$ reacts like Ph_2Hg but after 2 months like Et_2Hg. All aromatic RHgCl react in Me_2CO thus: $2RHgCl + SnCl_2 = R_2SnCl_2 + 2Hg + SnCl_4$. All the RHgX compds. whose corresponding R_2Hg react with alc. above react in alc. this reaction; $RHgCl + SnCl_2 + EtOH = RH + Hg + EtOSnCl_3$. The RHgBr compds. react according to both $2RHgBr + SnBr_2 = R_2SnBr_2 + 2HgBr$ and $RHgBr + SnBr_2 = RSnBr_3 + Hg$. W. F. HARRINGTON

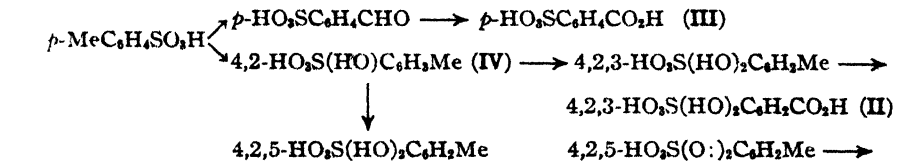


Aromatic boron compounds and the aryl mercury salts obtained from them. W. KÖNIG AND W. SCHARRNBECK. *J. prakt. Chem.* **128**, 153–70(1930).—The B compds. were prepd. because of their possible chemotherapeutic interest. *p-Bromophenylboric acid*, m. 260°, was obtained from *p*-BrC_6H_4MgBr and iso-Bu borate in Et_2O; the *oxide*, BrC_6H_4BO, results by heating the acid at 105° or by standing over H_2SO_4 for several days, it m. 280°. *o*-ClC_6H_4MgBr gives *o-chlorophenylboric acid*, m. 149°. *p*-$MeOC_6H_4MgBr$ gives *p*-methoxyphenylboric acid, m. 207°; the *o*-isomer m. 105°; the *m*-isomer m. 147°. *p*-Tolylboric acid m. 245°; it readily yields the *oxide*, m. 259°; the *o*-isomer m. 168° and 168°; the *m*-acid m. 157°. α-Naphthylboric acid m. 202°; the *oxide* m. 207°; the β-acid m. 248° and 266°; the higher-melting form is changed to the lower melting by crystg. from hot H_2O. The tolylboric acids are oxidized by $KMnO_4$ to the carboxyphenylboric acids; the *p*-isomer m. 225°; the *o-isomer* m. 152°; the *m*-isomer m. 240° (*Pb salt*; *Ba salt*, crystg. with 1 H_2O; *Ag salt*). *Di-p-anisylboric acid*, m. 107°;

di(p-bromophenyl)boric acid, m. 113°; *di-β-naphthylboric acid*, b_{14} 135–8°, m. 172°. The following *Hg salts* were prepd. by treating the boric acid in H_2O with the Hg salt: *p*-BrC_6H_4HgCl, m. 235°; *p*-BrC_6H_4HgOAc, m. 188°; *o*-ClC_6H_4HgCl, m. 133°; *p*-$MeOC_6H_4HgO$; *p*-$MeOC_6H_4HgOAc$, m. 176.5°; *o*-isomer, m. 124°; *o*-$MeOC_6H_4HgCl$, m. 178°; *m*-isomer, m. 158°; *m*-$MeOC_6H_4HgCl.HgOAc$, m. 120°; *p*-MeC_6H_4HgCl, m. 232°; *p*-MeC_6H_4HgOAc, m. 147°; *o*-MeC_6H_4HgOAc, m. 101°; *o*-MeC_6H_4HgCl, m. 142°; *m*-isomer, m. 159°; *m*-MeC_6H_4HgOAc, m. 84°; α-$C_{10}H_7HgOAc$, m. 154°; β-isomer, m. 147°; β-$C_{10}H_7HgCl$, m. 271°; *p*-$HO_2CC_6H_4HgCl$, m. 272°; *o*-isomer, m. 131°; *m*-isomer, m. 258°; *m*-$HO_2CC_6H_4HgOAc$, m. above 310°. C. J. West

The oxidizing power of the chloramines. J. Koetschet, P. Koetschet and Pierre Viaud. *Helv. Chim. Acta* **13**, 587–619(1930).—Chloramine B ($PhSO_2NNaCl$) (I) when treated with acid gives *benzenedichlorosulfonamide* (II). In practice II is not isolated but is the active oxidizing agent. 4,3-$Me(O_2N)C_6H_3SO_2NH_2$ (XI) (45 g.) and 28 g. I were refluxed in 900 cc. H_2O contg. 6 cc. HOAc for 32 hrs. yielding 33 g. *o-nitro-p-sulfonamidobenzaldehyde* (III), m. 141–3°; *anil* (IV), m. 171–1.5°. III, recovered from IV, m. 149–51° (from H_2O); *phenylhydrazone* (V), m. 239° (from alc.); *p-nitrophenylhydrazone* (VI), m. 290° (from $PhNO_2$). The *phenylhydrazone* (VII) and *p-nitrophenylhydrazone* (VIII) of *p-sulfonamidobenzaldehyde* are yellow. The addn. of a NO_2 group in the hydrazone-benzene ring as in VIII does not alter the color, but added in the aldehyde-carrying ring, as in V and VI, it confers a red color. On the other hand, while the *Na salts* of V and VII are almost colorless, those of VI and VIII, with the NO_2 group in the hydrazine ring, are blue-violet. I (35 g.), 5 g. *2,5-*$Me(O_2N)C_6H_3SO_2NH_2$ (XII) and 0.7 cc. HOAc, heated for 14 hrs. in 100 cc. H_2O, gave no isolable aldehyde, but the *phenylhydrazone* of *p-nitro-o-sulfonamido-ps-benzaldehyde* (IX), $NH.SO_2.C_6H_3(NO_2).CHNHNHPh$, was prepd. from the reaction mixt., m. 228° (from alc.). Similarly, PhMe gave 26.5% BzOH, isolated as the phenylhydrazone, m. 148–52°. *o*-$O_2NC_6H_4Me$ gave 4.8% of *o*-$O_2NC_6H_4CHO$ (*phenylhydrazone*, m. 152–3°). *m*-Xylene gave 13% of *m*-MeC_6H_4CHO (*phenylhydrazone*, m. 75–81°). *p*-Xylene gave 26.5% of *p*-MeC_6H_4CHO (*phenylhydrazone*, m. 106–10°) (from 50% alc.). Five g. *p*-$MeC_6H_4SO_2NH_2$ and 2 g. halazone (X) (with NaOH to give the H_2O sol. Na salt), heated for 14 hrs. in H_2O, gave yields, varying with the dilu. and duration of reaction, of the *phenylhydrazone* of *p-sulfonamidobenzaldehyde* (max. yield 1 g.). Similarly *o*-$MeC_6H_4SO_2NH_2$ gave 21.5% of aldehyde. X and XI gave 16% III. X and XII gave 25% of IX. X with *2,4-*$(H_2NSO_2)_2C_6H_3Me$ gave 20% of the *phenylhydrazone* of *2,4-disulfonamidobenzaldehyde*, $HN.SO_2.C_6H_3(SO_2NH_2).CHNHNHPh$, m. 241–2° (from alc.). The following compds. were derived from the hydrolysis products of *chloramine T:* *p-*$Me_2NSO_2C_6H_4CHO$ gave a *p-tolylhydrazone*, m. 160° (from 50% alc.), and an *asym. phenylmethylhydrazone*, m. 134–5° (from alc.). XII with KOH gave the corresponding *alc.*, m. 83–4° (from PhH-ligroin), and the *acid*, m. 247–8° (from H_2O). The following products were derived from the hydrolysis products of *chloramine TO* (XV): *o-sulfamidoanhydrobenzyl alc.* (XIII); *N-Ac deriv.*, $AcN.SO_2.C_6H_4.CH_2$, m. 108–9° (from PhH-ligroin), Bz deriv. m. 117–7.5° (from 40% alc.); *benzenesulfonyl deriv.* m. 174–5° (from alc.); *β-naphthalenesulfonyl deriv.* m. 214° (from alc.). XIII (1.5 g.) gave 1.25 g. *methylated deriv.*, m. 126–7° (from alc.), which was oxidized with alk. $KMnO_4$, yielding *o-methylsulfamidobenzaldehyde; phenylhydrazone*, m. 147–9°. *o-Sulfonamido-ps-benzaldehyde* (XIV); *methylphenylhydrazone*, m. 165° (from 60% alc.); *p-tolylhydrazone*, m. 207–9° (from 50% alc.). XIV dehydrated with H_2SO_4 gave *1-S-dioxy-α,β-benzylisothiazole*, $C_6H_4.CH:N.SO_2$, m. 257–8° (from $PhNO_2$ (alc.)). XIV was condensed with $PhNH_2$, yielding *1-S-dioxy-2,3-dehydro-3-p-aminophenyl-α,β-benzylisothiazole*, m. 236–7° (from alc.), and, condensed with $PhNMe_2$ (XVII), gave the corresponding *dimethylamino deriv.*, m. 152–4° (from PhH-ligroin). From the hydrolysis of XV a compd. (XVI), m. 141°, was also obtained; *Ac deriv.* m. 250–4°. XVI was not attacked by 40% NaOH at 25–30°, but when heated on the steam bath yielded the resp. *alc.* (XIII) and *aldehyde* (XIV). XVI with 3% or 25% Na_2SO_3 gave the same products. XVI was synthesized from XIII and XIV. Also derived from XV was another unnamed compd. (XVII) m. 263°, which was split by the action of $PhNHNH_2$ into *methyl-o-sulfonamidobenzaldehyde phenylhydrazone*, m. 153° (from dil. alc.) and XIII. —U on hydrolysis also gav

(XVI)



(XVII)

saccharin, which with XVII yielded *methylsaccharin*, m. 132–3°, showing XVII to be a good methylating agent for saccharin. T. H. RIDER

Aromatic fluorosulfonates. WILLY LANGE AND EMIL MÜLLER. *Ber.* **63B**, 2653–7 (1930).—Ph-, b_{754} 179–6° (yield 40%), *o*-tolyl-, b_{754} 191.6–192.6° (yield 43%), diphenylene-1,4-di-, m. 94.8° (yield 5%), *p*-chlorophenyl-, b_{753} 208–211° (yield 37%), *o*-, b_{26} 152° (yield 8%), *m*-, b_{22} 154° (yield 12%) and *p*-nitrophenyl-fluorosulfonates, b_{19} 156° (yield 12%), were prepd. by heating the corresponding diazonium fluorosulfonic acids (*C. A.* **21**, 3500). All are stable to boiling H_2O and acids but are very slowly hydrolyzed by alkali. V. F. HARRINGTON

The electrochemical oxidation of 1-methyl-4-benzenesulfonic acid. MORIAKI YOKOYAMA. *Helv. Chim. Acta* **13**, 1257–64(1930).—The electrochem. oxidation of *p*-$MeC_6H_4SO_3H$ acid takes the following course:

was obtained from the recrystn. of the ether-sol. product. II was identified as the Ba salt from the portion not pptd. with $Pb(OAc)_2$. III was identified by color reactions and by analysis of the Ba salt from the fraction pptd. with $Pb(OAc)_2$. The electrochem. oxidation of IV gave I, m. 199°, and II, identified by analysis of its Ba salt and by its color reactions. RACHEL BROWN

Firmness of attachment of alkyl groups in the benzene nucleus. K. v. AUWERS AND J. JANSSEN. *Ann.* **483**, 44–65(1930); cf. *C. A.* **22**, 3646.—The Fries transformation of various 2,6-dimethyl- and 2-methyl-6-ethyl-4-alkylphenyl acetates has been effected by the methods previously used. *vic-m-Xylenyl propionate*, pale rose, b. 234–6°; $AlCl_3$ gives *2,6-dimethyl-4-propiophenol*, m. 106–6.5°; reduction by Clemmensen's method gives *2,6-dimethyl-4-propylphenol*, m. 33–4°, whose *acetate* b. 252–60°. *vic-m-Xylenyl butyrate*, pale yellow, b. 248–50°; *2,6-dimethyl-4-butyrophenol*, m. 124–5°; *2,6-dimethyl-4-butylphenol*, b_{20} 138–46°, m. 32.5–3.5°; *acetate*, b. 268–76°. *vic-m-Xylenyl heptoate*, b_{12} 162–4°, *2,6-dimethyl-4-heptoylphenol*, pale yellow, m. 92–3°; *2,6-dimethyl-4-heptylphenol*, b_{12} 170–85°, m. 48.5–9°; *acetate*, m. 37.5–8°. *vic-m-Xylenyl dodecoate*, b_{12} 216–8°, m. 28.9°. *2,6-dimethyl-4-laurylphenol*, m. 52–3°; *2,6-dimethyl-4-dodecylphenol*, m. 65–6°; *acetate*, m. 57–8°. *vic-m-Xylenyl benzoate*, b. 310–20°, m. 40.5–1°; *2,6-dimethyl-4-benzoylphenol*, m. 142–2.5°; *2,6-dimethyl-4-benzylphenol*, b_{20} 195–200°, m. 66.5–7.5°; acetate, b. 324–6°. The Fries transformation of the above acetates affords, in all cases, unchanged acetate, the corresponding phenol and 3,5,4-$Me_2(HO)C_6H_2Ac$; small amts. of unidentified *o*-hydroxyketones are formed with the Pr, Bu and heptyl derivs. *2-Methyl-6-ethylphenyl propionate*, b. 244–6°; *butyrate*, b. 258–61°; *heptoate*, b_{12} 172–4°; *dodecoate*, b_{12} 218–20°. *2-Methyl-6-ethyl-4-propiophenol*, m. 101–2°; *4-butyro deriv.*, m. 86–7°; *4-heptoyl deriv.*, m. 56–7.5°; *4-lauryl deriv.*, m. 44.5–5.5°. *2-Methyl-4-propyl-6-ethylphenol*, b_{15} 130–3° (*phenylurethan*, m. 140.5–1.5°; acetate, pale yellow, b. 264–6°), the Fries transformation gives a little *o*-hydroxyketone and regenerated phenol. *2-Methyl-4-propylphenol*, b_{10} 117° (*phenylurethan*, m. 136°) yields an *acetate*, b_{11} 125°, giving *2-methyl-4-propyl-6-acetophenol*, pale yellow, b_{12} 136° (*p-nitrophenylhydrazone*, ocher-yellow, m. 216–7°). *2-Methyl-4-butyl-6-ethylphenol*, pale yellow, b_{18} 146–50° (*phenylurethan*, m. 117–9°); *acetate*, b. 270–80°; the Fries transformation gives the phenol and *2-methyl-4-butyl-6-acetophenol*, b_{12} 152–4° (*p-nitrophenylhydrazone*, red, m. 168–70°), synthesized from *2-methyl-4-butylphenyl acetate*, b. 268–70°. *o*-Tolyl butyrate, b. 237–40°. *2-Methyl-4-heptyl-6-ethylphenol*, m. 26–8°; *acetate*, b_{18} 184–94°, the Fries transformation gives the phenol and a little unidentified ketone. *2-Methyl-4-dodecyl-6-ethylphenol*, m. 51–2°; *acetate*, m. 41–3°; the Fries conversion gives small quantities of the phenol and 2,6,4-MeEt(OH)C_6H_2Ac. In these transformations the Et group is generally eliminated exclusively. *m-4-Xylenyl heptoate*, b_{16} 180–2°; *2,4-dimethyl-6-heptoylphenol*, pale yellow, b_{16} 186–90°; reduction gives *2,4-dimethyl-6-heptylphenol*, b_{16} 172–8°, m. 39–40°; *acetate*, b_{12} 180–8°; the Fries transformation gives mainly 3,5,2-$Me_2(HO)C_6H_2Ac$; the heptyl group is replaced by Ac. *2-Methyl-4-ethylphenyl propionate*, b_{16} 136–8°; *2-methyl-4-ethyl-6-propionylphenol*, yellow oil, b_{16} 134–8° (*phenylurethan*, m. 131–1.5°); *acetate*, b_{16} 142–6°; the Fries transformation

ives approx. equal amts. of *2-hydroxy-3-methyl-5-propylacetophenone*, m. 101° (also btained from *2-methyl-6-propylphenyl acetate*, b_{11} 117°) and an unidentified *o*-hydroxy-etone. *2-Methyl-4-ethyl-6-allylphenol*, b_{15} 120–5° ($FeCl_3$ reaction green); *acetate*, ale rose, b. 250–60°. *2-Methyl-4-ethyl-6-benzylphenol*, b_{12} 188–94° (*phenylurethan*, m. 42–3°); *acetate*, b_{12} 194–8°. Both acetates are converted into 3,5,2-MeEt(HO)C_6H_2-ic. The results show that the ease of elimination of the Et, Pr and Me groups is in the rder named. *o-Hydroxypropiophenone oxime*, m. 93.5–4°. *2-Hydroxy-5-propylaceto-henone*, yellow, b_{10} 145–7° ($FeCl_3$ reaction deep violet). Reduction gives *2-ethyl-4-ropylphenol*, yellow, b_3 245–6°; *acetate*, b. 244–6°; *2-hydroxy-3-ethyl-5-propylaceto-henone*, b_{18} 140–1°; $FeCl_3$ reaction green; *p-nitrophenylhydrazone*, m. 152.5–3.5°.

C. J. West

Identification of phenols. C. Frederick Koelsch. *J. Am. Chem. Soc.* **53**, 304–(1931).—Aryloxyacetic acids, easily prepd. from $ClCH_2CO_2H$ and phenols in aq. NaOH, re recommended as derivs. for the identification of the latter compds. The results vith 20 phenols are given, the following new derivs. being prepd.: *o-chlorophenol*, m. 43–5°; *m-deriv.*, m. 108–10°; *m-bromophenol*, m. 107–8.5°; *o-iodophenol*, m. 134–5°; *n-deriv.*, m. 114–5.5°; *p-methoxyphenol*, m. 110–2°. No derivs. were obtained with *o-* nd *p*-$O_2NC_6H_4OH$ and the yield was unsatisfactory with the *m*-isomer. C. J. W.

Derivatives of the *m*-xylenols. I. Intermediate products from *m*-5-xylenol 5-hydroxy-1,3-dimethylbenzene). F. M. Rowe, S. H. Bannister, R. R. Seth and R. C. Storey. *J. Soc. Chem. Ind.* **49**, 469–73T(1930).—3,5-$Me_2C_6H_3OH$ (I) was ni-rated with $NaNO_3$-H_2SO_4-H_2O mixt. at 28°, and gave 14.6% 4-nitro-*m*-5-xylenol (II), ellow needles from MeOH, m. 66°, and 2.4% 2-nitro-*m*-5-xylenol (III), pale yellow eedles from dil. HCl, m. 107–8°. I in HOAc, treated with 83% HNO_3 at 5°, then varmed to 60°, gave a resinous product from which 29.2% of II was isolated by steam listn., and 18.3% of III by crystn. from dil. HCl. Sulfonation of I with $ClSO_3H$ yielded a S-contg. by-product, insol. in H_2O, m. 111–2°, not a SO_3H acid. 2,4,6-$Me_2(HO)C_6H_2$-SO_3H (IV) is best prepd. by the action of cold $H_2SO_4.H_2O$ on I, and IV isolated as the Na alt from the Ca salt with Na_2CO_3. Sulfonation occurs ortho to the OH. The sulfona-ion mixt., contg. IV, was nitrated directly, the SO_3H group hydrolyzed, giving a total of 38.3% of II and 29.2% of III, based on I. III was nitrated in HOAc with concd. HNO_3, giving 84.6% of 2,4-dinitro-*m*-5-xylenol (V), pale yellow needles from H_2O, m. 115–6°. Nitration of II in H_2SO_4 gave 39.3% of V and a small amt. of 2,4,6-trinitro-*m*-5-xylenol (VI), m. 107–8°. Nitration of IV gave V, VI and dinitro-*m*-5-xylenolsulfonic acid, which yielded V on hydrolysis. 4,6-Dinitro-*m*-5-xylenol, pale yellow leaflets from H_2O, m. 126–7°, was formed as a by-product in an attempted mono-nitration of a sulfo-nation mixt. Treatment of I with *p*-$MeC_6H_4SO_2Cl$ in C_5H_5N gave *p*-toluenesulfonyl-*m*-5-xylenol (VII), m. 83°. VII was nitrated under various conditions, and the nitration product hydrolyzed, yielding I and III or V. Hydrolysis of the trinitro deriv. (VIII) of VII, m. 148–9°, gave V, indicating that VIII has the structure 3,5,2,4 $Me_2(O_2N)_2C_6HO_2$-$SC_6H_2(NO_2)Me(3,4)$. 2-Amino-*m*-5-xylenol (IX), m. 182°, was prepd. by coupling PhN_2Cl with I and reducing with $Na_2S_2O_4$; also from 3,5,4-$Me_2(ON)C_6H_2OH$ (m. 182°) by alk. reduction with $Na_2S_2O_4$; di-Ac deriv., m. 182°. 4-Amino-*m*-5-xylenol, m. 163°, was obtained in 71.6% yield from II by reduction with $Na_2S_2O_4$. Di-Ac deriv. m. 87–8°. Attempts to prep. 2,4-dinitro-4′-hydroxy-2′-6′-dimethyldiphenylamine (X) from IX and 2,4-$(O_2N)C_6H_3Cl$ yielded only the 2″,4″-dinitrophenyl ether of X, m. 283–4°. *m*-5-Xylenol Me ether (XI), b. 194°, was obtained in 86.7% yield by the action of Me_2SO_4 on I. The nitro derivs. of XI were best prepd. by methylating the corresponding nitro-xylenols with Me_2SO_4 or MeI. The following Me ethers were prepd.: of II (XII), m. 5–6°; of III, m. 53°; of V (XIII), m. 172°. Nitration of XI gave 24% of the Me ether of V and some Me ether of VI, m. 124–5°. XII with $SnCl_2$ gave 80% of 4-amino-*m*-5-xylenol Me ether (XIV), m 36–7°; di-Ac deriv. m. 80–1°. Treatment of XII with $Na_2S_2O_4$ gave the Na 4-amino-*m*-5-xylenol methyl ether-sulfonate (97.3%), readily hydrolyzed to XIV. XIII was reduced with Na_2S, giving 76.1% of 2-nitro-4-amino-*m*-5-xylenol Me ether, yellow tables, m. 91°.

G. R. Yohe

Autoxidation reactions. II. Mechanism of the autoxidation of certain esters. Nicholas A. Milas. *J. Am. Chem. Soc.* **53**, 221–33(1931); cf. *C. A.* **24**, 1629.—Evidence is presented to show that the dehydrogenation theory of Wieland, as applied by W. and Wingler (*C. A.* **17**, 2558) to the autoxidation of ethers, is untenable. The oxonium peroxide theory, based on previous views of M., is proposed to explain this behavior. The rate of O absorption by $(PhCH_2)_2O$ is reported at 40° and the effect on this rate of Au, Ag, Cu, Fe and Hg, of H_2O, I, picric acid and benzoquinone has been studied; the metals show a definite acceleration effect; H_2O acts as a neg. catalyst during the initial stages of the reaction, then as a pos. catalyst; I, picric acid and benzo-

quinone show a strong inhibitory action on the oxidation. Ultra-violet radiation shows a markedly accelerating action on the oxidation of various ethers; the rate of peroxide formation under these conditions depends largely on the type of groups attached to the O atom of the ether. *tert-Bu benzyl ether*, b. 205.6–8° (cor.), d_4^{25} 0.9439; concd. HCl gives $PhCH_2Cl$ and *tert*-BuCl; it oxidizes in the dark, giving *tert*-BuOH and hydroxybenzyl peroxide. Peroxides have been isolated from *tert*-BuOEt, *tert*-BuOPr, Bu_2O and BuOEt; these are colorless oils which explode violently on heating and possess an odor resembling that of peracids. They liberate I from KI and give a strong red color with *p*-$H_2NC_6H_4NMe_2$.HCl. These are different in properties from monohydroxy- and dihydroxyalkyl peroxides. C. J. West

Action of compounds of the diazomethane series upon thiono esters. Synthesis of ketene mercaptoles, acetal chlorides and thioacetal chlorides. Diphenyldiazomethane as a "free radical." Alexander Schönberg and L. v. Vargha. *Ann.* **483**, 176–89 (1930).—Ph_2CN_2 and $S:C(SPh)_2$ in Et_2O at room temp. for 2 days give *1,1'-diphenyl-2,2'-diphenylmercaptoethylene sulfide*, $Ph_2C.S.C(SPh)_2$, m. 135° and turns green at 200°; when covered with concd. H_2SO_4 it also turns a deep green. Heated in C_6H_6 with Cu-bronze, there results nearly quant. *1,1'-diphenyl-2,2'-(diphenylmercapto)ethylene*, $Ph_2C:C(SPh)_2$, pale yellow, m. 112°; the compd. is very stable to acid and alkali and is unchanged in the KOH melt at 200° for 30 min.; with concd. H_2SO_4 in AcOH, heated 5 hrs on the H_2O bath, there results Ph_2CHCO_2H. *1,1'-Di-p-tolyl-2,2'-(di-p-tolylmercapto)ethylene sulfide*, from $(p\text{-}MeC_6H_4)_2CN_2$ and $S:C(SC_6H_4Me\text{-}p)_2$, m. 134–5°; concd. H_2SO_4 gives a deep violet halochromy; Cu-bronze in C_6H_6 or heating at 200° for 1 hr. gives *1,1'-di-p-tolyl-2,2'-di-p-tolylmercaptoethylene*, m. 122–3°. Ph_2CN_2 and $S:C(SPh)Cl$ in Et_2O give *diphenylenephenylmercaptochloroethylene sulfide*, yellow, m. 110°; with Cu-bronze in C_6H_6 there results *diphenylenephenylmercaptochloroethylene*, yellow, m. 133°; hydrolysis with H_2SO_4-AcOH gives fluorenecarboxylic acid. Ph_2CN_2 and $SC(OPh)Cl$ in C_6H_6 4 days at room temp. give *diphenylenephenoxychloroethylene*, yellow, m. 114–5°. *2,4,6-Trichlorophenylthionocarbonyl chloride*, b_{12} 146–7°, with Ph_2CN_2 gives *1,1'-diphenyl-2-hydroxy-(2,4,6-trichlorophenyl)-2'-chloroethylene*, m. 91°. The formula

$$Ph_2{:}\,C\text{-}(N_2)\text{-}$$

is proposed for Ph_2CN_2 and its relation to Ph_2C is discussed. C. J. W.

Migration of acyl from sulfur to nitrogen. H. P. Lankelma and Albert E. Knauf. *J. Am. Chem. Soc.* **53**, 309–12(1931).—*N*-Acyl derivs. of 4,2-Cl(H_2N)C_6H_3SH (I) lose H_2O very readily to form the corresponding benzothiazoles. No rearrangement of Ac and Bz between S and N occurs upon acylation of these *N*-acyl derivs., which is unlike the typical behavior of an *o*-$H_2NC_6H_4OH$. I, light yellow, m. 198-201° (decompn.) (Hodgson and Wilson, *C. A.* **19**, 1412, give 120°); HCl salt (II), straw-colored, has a pronounced vesicant action upon the skin; I is very rapidly oxidized by the air to the disulfide. II, $PhNMe_2$ and BzCl, boiled 30 min., give *2-phenyl-5-chlorobenzothiazole* (III), m. 139°; Ac_2O gives the *2-Me deriv.* (IV), m. 68–9°. Heating 1 g. II, 1.8 g. BzCl and 5 cc. $PhNMe_2$ for 10 min. gives 1.35 g. *2-benzoylamino-4-chlorophenyl thiobenzoate*, m. 158–9°; sapon. by KOH-EtOH at room temp. gives *2-benzoylamino-4-chlorothiophenol* (V), m. 105–6°; recrystn. from EtOH or Et_2O gives III. *2-Acetylamino-4-chlorophenylthioacetate*, m. 150–1°; the free *thiophenol* m. 92–4° and on crystn. from EtOH gives IV. *2-Acetylamino-4-chlorophenylthiobenzoate* (VI), m. 141–2°; sapon. gives III; *2-benzoylamino-4-chlorophenyl thioacetate*, m. 129–30°; sapon gives V. Thus in the sapon. of VI a migration of Bz from S to N occurs. C. J. West

Mercury derivatives of acetylaminocresols. A. Proskouriakoff and R. J. Titherington. *J. Am. Chem. Soc.* **52**, 3978–84(1930).—Correction. "$NaHSO_3$" in the abstract in *C. A.* **24**, 5737, should read "$Na_2S_2O_4$." E. J. C.

Addition of phenols to the ethylenic linkage. Reaction mechanism and synthesis of certain phenolic ethers. Joseph B. Niederl and Samuel Natelson. *J. Am. Chem. Soc.* **53**, 272–7(1931); cf. *C. A.* **23**, 4471.—*m*-MeC_6H_4OH and EtCH:CHMe with H_2SO_4, added dropwise, at 0°, give *2-m-cresoxypentane(sec-amyl m-cresyl ether)* (I), b. 238°, n_D^{21} 1.500, d^{20} 0.920; HNO_3 and H_2SO_4 give trinitro-*m*-cresol. I was also prepd. from *m*-MeC_6H_4ONa and AmBr. It is assumed that H_2SO_4 first adds to the double bond and then H_2SO_4 is split off, giving the ether. The *p-isomer* b. 225°, d^{20} 0.920, n_D^{21} 1.505; the *o-isomer* b. 231–4°, d^{20} 0.915, n_D^{21} 1.493. *2,2,4-Trimethyl-4-phenoxypentane*, b_{40} 190°, b_{760} 258°, m. 12°, d^{20} 0.950, n_D^{21} 1.510; nitration gives picric acid. The *4-p-cresoxy deriv.* b. 272°, d^{20} 0.889, n_D^{21} 1.470; the *m-isomer* b. 273°, d^{20} 0.895, n_D^{21} 1.476; the *o-isomer* b. 271°, m. 6°, d^{20} 0.881, n_D^{21} 1.472; with HCl and $ZnCl_2$ the last compd. gives *diisobutyl-o-cresol* ($Me_2CH_2CMe_2C_6H_2(OH)Me$), m. 49–50°. C. J. West

Action of diazonium salts on unsaturated compounds. IV. ADOLFO QUILICO AND M. FRERI. *Gazz. chim. ital.* **60**, 606–19(1930); cf. *C. A.* **24**, 559.—In non-aq. soln. diazonium salts and unsatd. compds. do not undergo a coupling reaction, but a rupture of the unsatd. lateral chains, *i. e.*, a sort of oxidation (cf. *C. A.* **24**, 559), a reaction which was also found to be true of pyrroles (cf. *C. A.* **24**, 3508, 3797). In these reactions the well-known reaction between diazonium salts and satd. alcs. also takes place, which according to Angeli is of the type: $PhN(:NH):O + EtOH \longrightarrow PhN:NH + AcH \longrightarrow C_6H_6 + N_2 + AcH + H_2O$. With satd. alcs. this reaction proceeds only when hot, whereas with compds. of the $HOC_6H_4CH:CHMe$ type oxidation proceeds easily at 0° with formation of unidentified unstable products which are probably of the $HOC_6H_4CH:NNHAr$ type. In the Griess reaction, *N*-condensation products are not in general formed, probably because of the ready decompn. of the initial products, thus $ArN:NH \longrightarrow ArH + N_2$. On the other hand, in the expts. of Q. and F., the initial products can condense with the oxidation products of the unsatd. compd. to form *N*-derivs. To explain the mechanism of the reaction and to extend the investigation to new classes of unsatd. compds., a study was begun of the secondary products, with the further object of ascertaining in what form the =CHMe group of the lateral chain of the phenols is eliminated. It was shown in the earlier expts. that in the reaction of anethole, isosafrole (I), etc., with diazo-*p*-nitroaniline (II) a red compd. (III), m. 228°, is formed as a secondary product. It is prepd. most economically in the following way: *p*-Nitrobenzenediazonium sulfate (IV) (from 13.8 g. of $p\text{-}O_2NC_6H_4NH_2$ (V) diazotized with $AmNO_2$ in glacial AcOH and purified with Et_2O in the ordinary way) suspended in 95% EtOH (150 cc.), cooled to 0°, isosafrole (15 g. in a little EtOH) added, let stand 24 hrs., filtered, the residue extd. repeatedly with EtOH, the new residue (crude III) dissolved in C_5H_5N and fractionally pptd. with a little water, yields III, which has the *compn.* $C_{14}H_{12}N_6O_4$, sol. in concd. H_2SO_4 with intense violet color, with concd. KOH forms an almost black *salt*, whose hot aq. soln. is dark blue. II is easily reduced by $SnCl_2$ in HCl, and on evapn. of the soln. (freed of Sn) $p\text{-}C_6H_4(NH_3Cl)_2$ crystallizes. III is always obtained, whatever the particular phenol used. The reaction of IV and alk. $p\text{-}O_2NC_6H_4NHN:CHMe$ (VI) does not give good results because the alkali brings about a partial decompn. of VI and an impure product is obtained. The reaction proceeds much better in acidified dil. alc. V (2.8 g.), diazotized in the regular way, cooled, VI (3.4 g.) in EtOH (100 cc.) added, let stand until pptn. is complete, filtered and the residue washed with hot EtOH, yields 3 g. of *p-nitromethylformazyl*, $p\text{-}O_2NC_6H_4N:NCMe:NNHC_6H_4NO_2\text{-}p$ (VII), red, m. 228° (decompn.); its solns. in hot alkalies have an intense blue color. A mixt. of III and VII m. 228°, proving that III has the formula of VII. V (5.6 g.) in glacial AcOH, diazotized with concd. H_2SO_4 (3.8 cc.) and $AmNO_2$ (7 cc.) (if crystn. is difficult EtOH is added to the decanted oil), filtered, washed with cold EtOH, the IV dissolved in boiling 95% EtOH (200 cc.), evapd. to a small vol. on a water bath, filtered and the residue washed with hot EtOH, yields $[p\text{-}O_2NC_6H_4NHN:CH\text{-}]_2$ (VIII), m. around 310° (cf. 308-11° of Wohl and Neuberg, *Ber.* **33**, 3107 (1900)). The formation of VIII in this way gives further proof of the compn. of III, and is a notable example of the oxidizing power of diazo compds. which effect not only the well-known oxidation: $EtOH \longrightarrow AcH$, but also $EtOH \longrightarrow CHO.CHO$. Since a small quantity of III is formed from II and alc. $p\text{-}H_2NNHC_6H_4NO_2$, thus $EtOH \longrightarrow AcH \longrightarrow MeCH:NNHC_6H_4NO_2 \longrightarrow$ VII, it is probable that in the cleavage of propenylic derivs like anethole by diazonium salts the 2 parts of the mol. reunited from the double bond behave equally, with formation of the phenylhydrazones of the corresponding aldehydes, the formation of the formazylic deriv resulting from subsequent action of the diazo compd. on the acetaldehyde phenyl hydrazone. In this connection expts. are in progress in which the ratio between the diazonium salt and the unsatd. compd. are varied. *p*-Propenyldimethylaniline (IX) was prepd. by the method of Sachs (*Ber.* **38**, 514(1905)), and for the following synthesis was sufficiently pure after simple pressing on a porous plate. IV (from 2.8 g. of V diazotized in glacial AcOH with $AmNO_2$), suspended in EtOH (50 cc.) and added slowly to ice-cold alc. IX (3.2 g. in 100 cc.), let stand 1 day, evapd. on a water bath to incipient crystn., cooled, filtered and the residue recrystd. from hot EtOH, yields *dimethylaminobenzaldehyde p-nitrophenylhydrazone sulfate* $(Me_2NC_6H_4CH:NNHC_6H_4NO_2)_2.H_2SO_4$ (X), lustrous orange, m. 128–32°, slowly turns dark on exposure to air and light; boiled with aq. Na_2CO_3 it is transformed with recrystn. from EtOH, into free $Me_2NC_6H_4CH:NNH\text{-}C_6H_4NO_2$, which is known in 2 stereoisomeric forms (cf. Vecchiotti, *Gazz. chim. ital.* **43**, ii, 641(1913)). The order of adding IV and IX was then reversed. Alc. IX (4.8 g. in 50 cc.), added slowly to ice-cold IV (from 4.2 g. of V) suspended in 100 cc. of EtOH, let stand 1 day, filtered and the residue washed with EtOH and dried at 80°, yields 10 g. of a *sulfate*, $C_{17}H_{17}N_5O_2.H_2SO_4$ (XI), violet-red with dark blue reflection, does not have a

definite m. p., gives intense red solns. in hot glacial AcOH (repptd. on cooling); boiled with aq. Na_2CO_3 and the product recrystd. from xylene or AmOAc it forms the *compd.* $C_{17}H_{17}N_5O_2$ which is probably the *oxotriazole*, $Me_2NC_6H_4\overline{C:N.N(C_6H_4NO_2).N:CMe}$ (XII), violet-red with silvery reflection, m. 232–3°, gives intense red solns. in hot mineral acids, is not altered by boiling several hrs. with Ac_2O (which excludes a secondary N atom), oxidized very slowly by hot alk. $KMnO_4$ but more readily by hot acidic $KMnO_4$, is rapidly decolorized by $SnCl_2$ in aq. HCl (only p-$H_2NC_6H_4NH_2$ was identified in the products), and heated in a sealed tube at 130–50° with fuming HCl it is decompd. with formation of a yellow *substance* now under investigation. The formation of XII can probably be accounted for thus: IX ⟶ $Me_2NC_6H_4C(:NNHC_6H_4NO_2)C(:NNHC_6H_4NO_2)Me$ ⟶ $Me_2NC_6H_4\overline{C:N.N(C_6H_4NO_2).N(C_6H_4NO_2).N:CMe}$ ⟶ XII, is a synthesis like the formation of oxotriazoles from oxazones (cf. v. Pechmann, *Ber.* **21**, (1888)). Crystd. AcONa (4–5 g.), added to aq. IX (1.61 in 50 cc. contg. AcOH), made ice-cold, aq. p-$O_2NC_6H_4N_2Cl$ (from 1.38 g. of V and filtered) added dropwise, let stand several hrs., filtered and the residue washed with water, yields 100% of the *compd.* $C_{16}H_{16}N_4O_2$, probably p-$O_2NC_6H_4N:NC_6H_3(NMe_2)CH:CHMe$ formed by a normal coupling reaction, amorphous, brown-red, softens around 65° and decomps. completely at 85°. C. C. Davis

Preparation of methyl ethers of the quinone oximes. Stig Veibel and Margrethe Hejde Simesen. *Ber.* **63B**, 2476–84(1930).—Of the 2 methods of prepg. quinone oxime Me ethers (quinone + NH_2OMe, and salts of quinone oximes (nitrosophenols) + MeI or CH_2N_2), the first gives the better yields but yields homogeneous products only with sym. quinones, and even then there are often formed difficultly separable mixts. of quinone, quinone monoxime ether and quinone dioxime ether. V. and S. therefore undertook to det. whether the yields by the 2nd method might not be increased by the use of a suitable methylating agent and found with a series of nitrosophenols that under certain conditions quite good yields of oxime ether can be obtained with Me_2SO_4 or p-$MeC_6H_4SO_2Me$ (I). That the products are really oxime ethers and not nitrosoanisoles was shown by their reduction with boiling 15% $TiCl_3$ to the aminophenols. Titration with $TiCl_3$ cannot be used, however, to det. the purity of the products, although alkyl substituents seem to facilitate the reduction so that dialkylquinone oxime ethers use up almost the calcd. quantity of $TiCl_3$. Quinone chloroimide with NaOMe gives indophenol-like products and not the oxime ether, but $Mg(OMe)_2$ does give a very small amt. of quinone ether. p-$O:C_6H_4:O$ with 1 mol. $MeONH_2.HCl$ in alc. at room temp. gave 59% of $O:C_6H_4:NOMe$; p-ONC_6H_4OH gave 28% with Me_2SO_4 in NaOH and 27% with I. 1,2,4-$O:C_6H_3Me:NOMe$ was obtained in 20% yield from 2,4-$Me(ON)C_6H_3OH$ with Me_2SO_4 and in 26% yield with I. 3,4-$Me(ON)C_6H_3OH$ gave 39% oxime ether, m. 73°, with Me_2SO_4 and 42% with I. *p-Xyloquinone oxime Me ether*, 4,2,5,1-$O:C_6H_2Me_2:NOMe$, yellow, m. 70.5–1°, was obtained in 70% yield from $Me_2(HO)C_6H_2NO$ and Me_2SO_4; xyloquinone and NH_2OMe yielded difficultly separable mixts. 1,2,5,4-$O:C_6H_2Me(CHMe_2):NOMe$ was obtained in 74% yield from nitrosocarvacrol with Me_2SO_4, and the isomeric *thymoquinone 1-oxime ether*, yellow, m. 35°, b_{18} 144–5°, in 80% yield from nitrosothymol; thymoquinone with NH_2OMe gives a difficultly separable mixt. of the 2 isomers. When thymol is nitrosated and, without isolating the NO compd., is then treated with HNO_3, it gives 4-nitrothymol whose *Me ether*, prepd. with Me_2SO_4, very faintly yellowish, m. 31.5°, b_{16} 173°; yield 53%. C. A. R.

Acetylation of *o*-hydroxy aldehydes. T. Malkin and M. Nierenstein. *J. Am. Chem. Soc.* **53**, 239–42(1931).—*o*-HO aldehydes may be acetylated with Ac_2O and anhyd. K_2CO_3 in the presence of Et_2O, which method avoids benzylidene diacetate formation. Thus, *o*-HOC_6H_4CHO, Ac_2O, K_2CO_3 and Et_2O give the Ac deriv., m. 38°, while without the Et_2O there results 2-acetoxybenzylidene diacetate, m. 107°. *Diacetyl-β-resorcylic aldehyde*, m. 69°. *Triacetylphloroglucinol aldehyde*, m. 101°; 2,4,6-triacetoxybenzylidene diacetate m. 157°. The use of Et_2O permits the control of all rise of temp. C. J. West

Some derivatives of veratrole and of methylvanillin. II. 2,3,6,7-Tetramethoxyanthraquinone. B. L. Vanzetti and A. Oliverio. *Gazz. chim. ital.* **60**, 620–32 (1930).—In a previous paper (cf. V., *C. A.* **21**, 1974) a curious transposition of veratril and of veratrilic acid to a condensation product of the quinone type is described. Because of the difficulty of obtaining this compd. and of its inactivity toward mild reagents, expts. were directed toward some other way of synthesizing it and thus identifying its constitution. Because of their extensive literature and their technical importance, anthraquinones were chosen as the field of investigation, and the most promising starting

point was in the direct condensation of a sym. dimethoxylated phthalic acid, *viz.*, *m*-hemipinic acid (I) with veratrole (II). I was prepd. by application of the condensation reaction of Perkin and Robinson, *viz.*, 3,4-$(MeO)_2C_6H_3CHO$ and Na in AcOEt formed 3,4-$(MeO)_2C_6H_3CH:CHCO_2H$, which reduced with Na-Hg formed 3,4-$(MeO)_2C_6H_3$-$CH_2CH_2CO_2H$. The latter with P_2O_5 condensed to 3,4-$(MeO)_2C_6H_2.CH_2.CH_2.CO$ and this was oxidized by HNO_3 (1:3) to I. Contrary to von Konek and Szamák (*C. A.* **16**, 2139) the condensation reaction of Perkin and Robinson gives good results. Thus obtained and crystd. from boiling water, I m. 174–5°, and when heated at 190–5° it partially sublimes and is transformed to *m*-hemipinic anhydride (III). For the condensation of III with II, the reaction of Bentley and Weizmann (cf. Beilstein **10**, 522; *Monatsh.* **6**, 380(1884)) and of Bistrzycki and Krauer (*C. A.* **18**, 241) was followed. B. and W. used CS_2 and B. and K used C_6H_6. In the present expts. C_6H_6 did not give good results because (1) it took part in the reaction with formation of *4,5-dimethoxy-2-benzoylbenzoic acid*, which has not been described before and which will be dealt with in a later paper and (2) in the presence of C_6H_6 the condensation product is partially demethylated. The reaction proceeded better in CS_2, and because the yield was low the product was not demethylated and was readily purified. III (10 g.), CS_2 (150 cc.), II (20 g.) and $AlCl_3$ (25 g.), heated 24 hrs. on a water bath, the CS_2 removed by distn., made ice-cold, dil. HCl added, excess II removed by steam distn., the residue filtered, 10% Na_2CO_3 added to the filtrate, acidified, the brown-yellow resinous mass crystd. from dil. EtOH, from C_6H_6 or from AcOH, yields 30% of *4,5,3',4'-tetramethoxy-2-benzoylbenzoic acid*, $(MeO)_2C_6H_3COC_6H_2(OMe)_2CO_2H$ (IV), m. 217–8° to a brown liquid Its soln. in concd. H_2SO_4 is carmine-red, and when warmed SO_2 is evolved and on diln. a greenish yellow flocculent *anthraquinone deriv.* is ppt'd. *NH₄ salt Ag salt*, by doubl decompn. with the NH_4 salt, turns yellow in light. IV (1 g.) in 10% aq. NaOH (25 cc.) and Zn dust (3 g.), boiled 1 hr., filtered, acidified with HCl, the ppt. digested with 10% Na_2CO_3 and the residue recrystd. from C_6H_6, dil. EtOH or dil AcOH, yields *5,6-dimethoxy-3',4'-dimethoxy-3-phenylphthalide* (V), $O.CO.C_6H_2(OMe)_2.CHC_6H_3(OMe)_2$, softens 235°, m. 238°, insol. in alk. carbonates and in NH_4OH, sol. in hot 10% aq. NaOH and KOH. A very small yield of V is also obtained when the reduction is carried out in acid medium. Zn dust (10 g.) and concd. HCl (10 cc.), added during 14 hrs. to IV (2.5 g.) in AcOH (50 cc) (keeping the soln. boiling), filtered hot, dild. with boiling water, cooled, the ppt. dissolved in dil. NH_4OH, filtered, acidified and the ppt. recrystd. from dil. EtOH, yields 2.1 g. of *4,5,3',4'-tetramethoxy-2-benzylbenzoic acid* (VI), m. 165–6°. VI (1 g.) in concd. H_2SO_4 (10 cc), kept ice-cold for 15 min., poured on ice, the ppt. digested with 10% Na_2CO_3, filtered, washed and dried, yields 100% of *2,3,6,7-tetramethoxy-9-anthrone*, $(MeO)_2C_6H_2<^{CH_2}_{CO}>C_6H_2(OMe)_2$ (VII), m. 282–4° (decompn.); in boiling KOH it has the *tautomeric anthranol form*, $(MeO)_2C_6H_2<^{CH}_{C(OH)}>C_6H_2(OMe)_2$ (VIII), and by the action of atm. O this soln. deposits VIII. VII was oxidized by 2 methods, (1) CrO_3 and (2) H_2O_2. CrO_3 in AcOH, added to VII (calcd. quantity) in boiling AcOH (1 g. of VII in 50 cc.) and filtered hot, yields *2,3,6,7-tetramethoxyanthraquinone* (IX), m. 345–6°, sublimes without decompn., gives an intense green soln. in concd. H_2SO_4 and on diln. it is repptd. unaltered, insol. in 10% KOH. VII (0.5 g.), AcOH (25 cc.) and 30% H_2O_2 (5 cc.), boiled 1 hr. and filtered hot, yields 100% of IX, m. 345°, slightly darker than when prepd. by oxidation with CrO_3. Thirty-five % HCHO (14 g.), added slowly to II (10 g.) in 70% H_2SO_4 (34 g.), let stand 2 hrs., and the ppt. recrystd. from C_6H_6, yields 2 3,6,7-tetramethoxydihydroanthracene (X) (cf. Robinson, *C. A.* 9, 1602). It is difficult to oxidize, for alk. $KMnO_4$ does not attack it, and CrO_3 in AcOH forms a mixt. of products which are difficult to sep. $Na_2Cr_2O_7$ (20 g.) in a little water and AcOH (100 cc.), added slowly to X (2 g.) in AcOH (20 cc.), refluxed 6 hrs., dild. with boiling water, filtered, the residue, washed with Na_2CO_3 and NaOH, digested in boiling AcOH, and filtered, yields a residue of IX, while the filtrate, let stand, ppts. an unidentified compd with a pearly aspect. IX (0.5 g.) and HBr (40 cc. of d. 1.49), heated 6 hrs. in a sealed tube at 170–5°, yield almost 100% of *2,3,6,7-tetrahydroxyanthraquinone* (XI), orange-yellow, turns brown above 360° and decomps. without fusion (partially sublimes), sol. in aq. alkalies with a green-yellow color (repptd. by acids); with Al salts it gives greenish lakes. On prolonged boiling in Ac_2O, XI forms, after recrystn. from AcOH, *2,3,6,7-tetraacetoxyanthraquinone*, lustrous straw-yellow, m. 300° (decompn.), insol. in dil. alkalies and in dil. NH_4OH.

C. C. Davis

Nucleus synthesis of ketimides and ketones by condensation of nitriles with aromatic and heterocyclic compounds. J. Houben. II. Syntheses with toluene, mesitylene, tetralin, phenol, 1,4,5-xylenol, 3,5-dimethylanisole, thymol and carvacrol. J. Houben and Walter Fischer. *Ber.* **63B**, 2455–63(1930); cf. *C. A.* **24**, 1106.—The Houben-Hoesch ketone synthesis has been extended to a whole series of further compds. By this method it is possible to prep. ketimide HCl salts, ketimides, ketones, acids, esters, amides and nitriles in a simple way and generally with very good yields. The working up of the reaction mixt. has also been improved. Instead of the "acid" method, the "alk." method or decompn. of the reaction mixt. with so much crushed ice that the temp. is greatly lowered as with a freezing mixt. are now often used, sensitive compds., especially the ketimides, being thereby protected from destruction. *p-Trichloroacetimidotoluene-HCl* (*trichloromethyl p-tolyl ketimide-HCl*) (80% from PhMe, CCl_3CN and $AlCl_3$ satd. with HCl), very hygroscopic and can be kept only in sealed vessels; when it is rapidly shaken under Et_2O with aq. $KHCO_3$ and the Et_2O layer is at once dried with Na_2SO_4 vacuum distn., it gives a liquid of const. b. p. (138–9° under 11 mm.) but contg. only about 33% of the ketimide with 66% ketone. A product 86% pure, b_{28} 158°, is obtained by extg. the $AlCl_3$-PhMe-CCl_3CN reaction product (decompd. with 5% NaOH) with ice-cold Et_2O. On the other hand, 2,4,6-$Me_3C_6H_2C(:NH)Me$ and its HCl salt had been readily obtained in good yield and it was apparently unchanged by long boiling with 39% HCl. Further study has shown that this was a mistake. The ketimide is not only very difficultly sapond. but the resulting *trichloroacetomesitylene* (I) is unexpectedly resistant to alkalies, and as the ketimide had always been tested for sapon. by heating a sample of the soln. with alkali and detg. the content of CO_2H acid it had been concluded, from the absence of acid, that the ketimide had not been sapond. It has now been possible, by boiling the ketimide 6 hrs. with 25% HCl, to obtain the *N*-free I, b_{10} 148–9°, converted by boiling 40% NaOH into $Me_3C_6H_2CO_2H$. Tetralin with CCl_3CN, PhCl and $AlCl_3$ gives 42% of a mixt. (yellow, extremely hygroscopic powder) of much *β*- with a little *α-tetralyl trichloromethyl ketimide*, converted by solid KOH and CaO into *β*-tetralincarboxylic acid and *α*-tetralin nitrile. Together with the ketimides is obtained 14% of a ketone, b_2 170–80° (slight decompn.), having the compn. of a *trichloroacetotetralin;* it was apparently the not quite pure *β*-compd. For the direct conversion of PhOH into *p*-$CCl_3COC_6H_4OH$, the method recently described, with "acid" working-up of the product, is the best, giving a 95% yield. The *ketimide-HCl*, light yellow hygroscopic powder, can be isolated in 18% yield by the alkali method. From 2,5-$Me_2C_6H_3OH$ are obtained *4-hydroxy-2,5-dimethylphenyl trichloromethyl ketimide-HCl*, bright yellow, m. 185° (decompn.) (free *ketimide*, m. 170 1° (decompn.)), and the *ketone*, m. 85–6°, quantitatively converted by aq. alkali into *2,5-dimethyl-4-hydroxybenzoic acid*, m. 182–4°. 3,5-$Me_2C_6H_3OMe$ gives 74% of a mixt. of *2,4,6-* and *2,6,4-dimethylmethoxyphenyl trichlorophenyl ketimide-HCl*, m. 130–5°, hydrolyzed by boiling 6 hrs. with 20% HCl to the *ketones*, b_{11} 168–70°, from which, by boiling 6–8 hrs. with 30% NaOH, was obtained v. Auwers and Sauerwein's $Me_3(MeO)C_6H_2CO_2H$, m. 163–7° (*C. A.* **17**, 732). From thymol are obtained 50% *4-hydroxy-5-isopropyl-2-methylphenyl trichloromethyl ketimide-HCl*, yellow, m. 170–5° (decompn.), and 23% of the *ketone*, m. 99–100°; free *ketimide*, m. 115–7°. Pure carvacrol, from carvone with boiling HCO_2H, b_{16} 120°, gives 66% of *4-hydroxy-2-isopropyl-5-methyl trichloromethyl ketimide-HCl*, decomps. around 180–90°; the free *ketimide* and the *ketone* are oils which do not distil without decompn. even in a high vacuum. The ketone gives an *acid* m. 161–4°, which is different from Kekulé's *o*-carvacrotinic acid, m. 136°, and must, therefore, be the *p*-acid, 5,2,4-$Me(Me_2CH)(HO)C_6H_2CO_2H$; it gives no $FeCl_3$ reaction.

C. A. R.

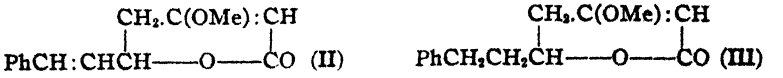
A new method for the preparation of cyclic nitriles by catalytic degradation. I. J. Houben and Walter Fischer. *Ber.* **63B**, 2464–72(1930).—The trichloromethyl ketimides of the type described in the preceding abstr. are smoothly converted not only by alc. and aq. alkali but also catalytically in Et_2O by small amts. of powd. KOH into cyclic nitriles and $CHCl_3$ without the alkali being in any way attacked. With the ketimides of the free phenols, where the HO group must be satd. with alkali before cleavage can take place, it is difficult to det. the amt. of alkali required for the cleavage, but it is believed that here, too, the process is catalytic. A procedure has been developed which permits of converting the ketimide directly, without purification, into the nitrile and also of sepg. the ketimide from the accompanying ketone. The method almost always gives good yields and has thus far failed in no case. Thus, from *p*-$MeC_6H_4C(:NH)CCl_3$ (85% pure), allowed to stand 2–4 hrs. under petroleum ether with powd. CaO and KOH (powd. under petroleum ether and dried over P_2O_5 at 100°), was obtained 75% *p*-MeC_6H_4CN which, while it did not solidify until cooled to 0°, yielded only *p*-

$MeC_6H_4CO_2H$ with acids and then alkali, and *p*-$MeC_6H_4CONH_2$ with MeOH-HCl. It is not clear what caused the depression of the m. p. of the MeC_6H_4CN. The crude mixt. of 2,4-$Me_2C_6H_3C(:NH)CCl_3$ (91%) and ketone obtained from *m*-xylene and CCl_3CN gives with powd. KOH-CaO 82% 2,4-$Me_2C_6H_3CN$, m. 24–5°. From 2,5-$Me_2C_6H_4C(:NH)CCl_3$ (85%) was obtained 98% 2,5-$Me_2C_6H_3CN$, begins to m. —3°, m. completely 6°. 2,4,6-$Me_3C_6H_2CN$, b. 225–30°, was obtained in 62% yield, based on the $C_6H_3Me_3$ used, without isolating the ketimide. The mixt. of little *α*- with much *β*-tetralyl CCl_3 ketimide HCl salts (see preceding abstr.) yields 14% *α*-cyanotetralin, m. 48–50°, the H_2O set free from the salts by the KOH converting the *β*-ketimide almost completely into the ketone and NH_3, which is recovered in about 68% yield as $C_{10}H_{11}CO_2K$. *p*-$HOC_6H_4C(:NH.HCl)Me$, allowed to stand 2 min. in 10% NaOH at 50°, gave *p*-$HOC_6H_4CO_2H$ and 25% *p*-HOC_6H_4CN. 2,5,4-$Me_2(HO)C_6H_2C(:NH)CCl_3$ was quant. converted in the same way into $Me_2(HO)C_6H_2CN$, m. 163–5°. *2,6,Dimethyl-4-methoxybenzonitrile*, m. 85–7°, was obtained in 52% yield, together with a substance, m. 49–55°, of the same N content, directly from 3,5-$Me_2C_6H_3OMe$ without isolating the ketimide. *p-Thymotinic nitrile*, m. 115–6°, was obtained in 81% yield from the ketimide-HCl, and in 61% yield directly from thymol. *p-Carvacrotinic nitrile*, m. 75–7°, was likewise obtained in 62% yield from the ketimide-HCl. C. A. R.

Derivatives of dulcin. E. Wertheim. *J. Am. Chem. Soc.* **53**, 200–3(1931).—Dulcin (I) and $ClCO_2Et$, heated in the free flame until homogeneous and then at 100° for 2 hrs., give *Et p-phenetylallophanate*, m. 139–40°, tasteless; with concd. NH_4OH at 100° for 4 hrs. there results *p-phenetylbiuret*, m. 185–6°, tasteless. Heating I and $ClCO_2Et$ at 175° for 2 hrs. gives $(p\text{-}EtOC_6H_4NH)_2CO$, m. 225–6°, and *bis(p-phenetyl)biuret*, m. 208–9°, the 2 compds. being sepd. by AcOH. *p*-$EtSC_6H_4NH_2$ and KCNO in HCl give *p-thiophenetylurea*, m. 149–50°; concd H_2SO_4 gives a colorless soln., becoming pale green on heating and colorless on cooling; the compd. has a very slight bitter taste. *p-Thioanisylurea*, m. 164–5°, tasteless. *p-Thiophenetylthiourea*, m. 136–7°, lasting bitter taste. *p-Thioanisylthiourea*, pale yellow, m. 198–9°, persistent bitter taste. C. J. West

Benzalpyruvic acid. L. Musajo. *Gazz. chim. ital.* **60**, 669–72(1930).—$PhCHBrCHBrCOCO_2H$ (I) has been previously described by several experimenters (cf. Erlenmeyer, *Ber.* **36**, 2528; Ciusa, *C. A.* **14**, 172; Reimer, *C. A.* **20**, 3164), but its m. p. has varied greatly. Reimer found 125–42° and explained it by liberation of HBr and formation of an unsatd. mono-Br deriv. Prepd. by M. by the old method, and crystd. by spontaneous evapn. of a concd. C_6H_6 soln., it m. 124°. When this is then kept in the fused state *in vacuo*, the m. p. rises to 142–3°. This may be due to loss *in vacuo* of solvent of crystn. In crystg. from C_6H_6, fractions were frequently obtained which m. 147–50°, and these had the same compn. When boiled in water, these fractions give the same mono-Br deriv. (II), m. 131° (cf. Reimer, *loc. cit.*). An isomerism may explain this range of m. ps., in which case it was of interest to prep. I from $PhCH_2CH_2COCO_2H$ (III) in its oil modification (cf. Claisen and Antweiler, *Ber.* **13**, 2123; C. and Claparède, *Ber.* **14**, 2472). Oily III absorbs Br, with formation of an oil which, boiled with water as before, yields II. From the decanted aq. liquor BzOH can be isolated, and when the brown resin remaining after the boiling water treatment is dried and purified with C_6H_6, a cryst. substance (IV), insol. in C_6H_6, is obtained. The yield of IV is 8.5 g. per 330 g. of III. Crystd. from AcOH, it m. 279°. It does not contain Br, gives yellow solns. in alk. hydroxide and carbonates and NH_4OH, from which it is repptd. on acidification. Heated with alkalies, it gives intense yellow solns., with formation of BzH. Treated in AcOH with Br, IV forms a bright red *substance* (V), m. 210°, whereas with alc. Br it forms a yellow substance (VI), m. 210°, with properties similar to those of V. V and VI do not contain Br, and their solns. in cold alkalies are yellow and evolve BzH. Further data on IV are to be published later. C. C. Davis

The action of potassium hydroxide on the esters of the tetracarboxylic acids of the dimalonic acid series (preparation of ethylphenylpropionic acid). Hsuing T. Lo. *Bull. Chem. Soc., Japan* **5**, 326–33(1930).—An attempt was made to prep. *o*-$C_6H_4(CH_2CH_2CO_2H)_2$ (I) by heating *o*-$C_6H_4[CH_2CH(CO_2Et)_2]_2$ (II) 3 hrs. with alc. KOH (25%), acidifying with dil. H_2SO_4, extg. with ether and heating to 150° (Perkins method). The product contained only a small quantity of I and nearly 90% of a new compd., *o-ethylphenylpropionic acid* (III), m. 103°. Lower concns. of KOH gave less of III and more of I. The *p*-isomer of II gives *p-ethylphenylpropionic acid*, m. 114–5°. The *m*-compd. gave only $C_6H_4(CH_2CH_2CO_2H)_2$. Heating I alone or with concd. KOH does not form III, therefore III is probably formed by the direct loss of 3 mols. CO_2. The Ag salts of I and III, prepd. from soln. of the NH_3 salt by pptn. with $AgNO_3$, are amorphous



powders which on heating with EtI and ether yield *Et o-ethylphenylpropionate*, b_{10} 131°, and *Et p-ethylphenylpropionate*, b_{15} 141°. JANET E. AUSTIN

Minjak Pelandjau, the exudate from the wood of Pentaspadon motleyi Hook f. P. VAN ROMBURGH, A. G. VAN VEEN, AND A. J. HAAGEN SMIT. *Proc. Acad. Sci. Amsterdam* **33**, 589–94(1930); cf. *C. A.* **24**, 124.—Jones and Smith (*C. A.* **24**, 3532) give to pelandjauic acid provisionally the structure 2,6-$[Me(CH_2)_4CH:CHCH:CH(CH_2)_7]$-$(HO)C_6H_3CO_2H$. R., V. and S. prepd. *tetrahydropelandjauic acid*, $C_{23}H_{42}O_3$. Decarboxylation of the acid yielded a phenol which gave no reaction with $FeCl_3$ and was insol. in NaOH. It contained 1 OH group as detd. by the method of Zerevitinov. Upon hydrogenation with Pt black 5 mols. of H was taken up. HO detns. in the decahydro product added evidence that the phenol mol. was $C_{24}H_{37}OH$. In 1 expt. a substance was obtained which did not contain O. The phys. properties and the process in tetrahydration of this hydrocarbon indicated it to be $C_6H_{11}C_{18}H_{37}$. *Methyl tetrahydro-* and *decahydropelandjauate Me ether* were prepd. and analyzed; the *tetrahydro ether ester* was oxidized with CrO_3 and its phys. properties were detd.; methylation of the phenol $C_{24}H_{37}OH$, hydrogenation of the Me ether of the phenol, oxidation of the Me ether, dehydration of the decahydrophenol and ozonization of the hydrocarbon $C_{24}H_{46}$ lead to the conclusion that the formula of pelandjauic acid is $C_6H_2(CO_2H)(OH)R_6R_1$, the side chain R_6 containing 2 double linkages and R_1 being a Me group. R., V. and S. give the full structure of the acid as 4,2,3-$Me(HO)[Me(CH_2)_4CH:CHCH_2CH:CH(CH_2)_7]C_6H_2CO_2H$ which is different from the formula proposed by Jones and Smith. *Ibid* 690–3.—R., V. and S offer further evidence supporting their previous suggestion that the hydrocarbon isolated by them, when catalytic hydrogenation of the phenol (obtained by decarboxylation of pelandjauic acid) was carried to completion, may contain a Me group in the benzene nucleus. Two expts. were added: 1. Distn. of decarboxylated tetrahydropelandjauic acid over Zn. Three fractions were thus obtained from 1 g. of the original material, (*a*) 0.2 g., b_{15} ≈ 70°, (*b*) 0.25 g., b_{15} ≈ 170°, (*c*) 0.2 g., $b_{0.7}$ ≈ 200°. The fractions were studied with picric acid, picrates and otherwise, and the authors were led to a confirmation of their original suggestion. 2 Distn. of the original phenol over Zn dust. Naphthalenes were distd. at 760 mm. and yielded the following fractions: (*a*) 0.5 g., b. 170–235°, (*b*) 0.5 g., b. 235–40°, (*c*) 0.3 g., b. 240–300°. Studies of the properties of these fractions further strengthened the original assumption. From addnl. studies the authors conclude that the cryst. acid obtained from *minjak pelandjau* must possess the structure 2,3-$HO(C_{17}H_{31})C_6H_3CO_2H$ while to the liquid acid they assign the formula 4,2,3-$Me(HO)(C_{17}H_{31})C_6H_2CO_2H$. B. S. LEVINE

Tannins and similar compounds. XXV. Catechols of the cola nut. KARL FREUDENBERG AND LEONIE OEHLER. *Ann.* **483**, 140–3(1930); cf. *C. A.* **21**, 2263.—The cola nut contains *d*-catechol and *l*-epicatechol; the names colatin, colatein and cola-catechol can, therefore, be stricken from the literature. This is the first time that these 2 catechols have been found together. C. J. WEST

Constituents of kawa root. X. Kawain and dihydrokawain. W. BORSCHE AND W. PEITZSCH. *Ber.* **63B**, 2414–7(1930); cf. *C. A.* **24**, 1099–1100.—It was shown in Paper VIII that kawaic acid (I) is the CH_2O_2-free mother substance of methysticinic acid, $CH_2O_2C_6H_3CH:CHCH:CHC(OMe):CHCO_2H$, and it was concluded that kawa root also probably contains, in addn. to methysticin, $C_{13}H_{14}O_5$, the doubly unsatd. lactone kawain (II). Considerable difficulties were at first met in attempts to isolate it, but this was finally effected. Pure II is a beautifully crystd. substance, optically active like methysticin and extraordinarily similar to it in its chem. behavior. Hot NaOH smoothly converts it into I and catalytic hydrogenation gives a mixt. of much *dihydrokawain* (III) and a little *tetrahydrokawaic acid*, $PhCH_2CH_2CH_2CH_2C(OMe):CHCO_2H$ (IV). III was also found (WITH J. NIEMANN) in kawa resin. Alkali isomerizes it to *dihydrokawaic acid*, $PhCH_2CH_2CH:CHC(OMe):CHCO_2H$ (V). Com. kawa resin in 250-g. portions is dissolved in 2 l. Et_2O, filtered, the Et_2O shaken out 3 times with 3% NaOH, washed to neutrality with cold satd. NaCl, turbined several hrs. with Na_2SO_4 and evapd., giving about 225 g. of residue. This is then extd. 10 hrs daily for 6–7 days with petroleum-hexane in a continuous extractor, the extractive which seps. in the boiling flask being separately rinsed out every morning with Et_2O. When the combined Et_2O solns. are evapd. the residue begins to crystallize, especially if seeded with II and stirred. After several weeks the crystals are washed with Et_2O until the residue is colorless. Most of the II is present in the exts. of the 2nd–4th days and is obtained almost pure after 1 crystn. from MeOH-Et_2O. The total yield of II is about 25% of the purified resin. It is purified by distg. (195–7° under 0.1 mm.) and crystg. from MeOH-Et_2O. It begins to sinter 102°, m. 105–6°, is sol. in concd. H_2SO_4 with red color, $[\alpha]_D^{20}$ 105° (1% soln. in abs. alc.). III (3 g. from 4.6 g. II), m. 56–8°, sol. in H_2SO_4 without

color, $[\alpha]_D^{20}$ 30° (1% soln. in abs. alc.). V, m. 139–40° (gas evolution). As III is more sol. than II, it is found in the Et_2O filtrates from the crude II obtained in the 2nd–4th day exts. of the resin. It seps. in yellowish cryst. aggregates, m. 50–4°, of a III-II

mixt. or "pseudokawain." **XI. Synthesis of methysticinic acid and kawaic acid.** W. Borsche and B. R. Blount. *Ibid* 2418–20.—B. and Peitzsch recently demethylated the Me esters of methysticinic (I) and kawaic acid (II) by cautious heating with HCl in MeOH to allomethysticin (III), $CH_2O_2C_6H_3CH:CHCH:CHCOCH_2CO_2Me$, and allokawain (IV) and concluded that I and II are the β-methoxycrotonic acids, $=CH-C(OMe):CHCO_2H$, isomeric with III and IV. On this conclusion are based the structures which have been assigned to methysticin, kawain and their dihydro derivs. It was desirable, therefore, to confirm it in another way, by regeneration from III and IV of the esters of I and II. B. and P. had already attempted to do this by the von Pechmann method but without satisfactory results because the CH_2N_2 used reacted too readily with the ethylene unions in III and IV to form stable addn. products contg. N The desired reaction has now been effected with surprising smoothness by the use of $Si(OMe)_4$ which Helferich and Haussen found an excellent means for prepg. di-Me acetals of unsatd. aldehydes. Under the conditions employed by B. and B., III and IV with $Si(OMe)_4$ gave the Me esters of I and II directly. C. A. R.

Deguelin. I. Preparation, purification and properties of deguelin, a constituent of certain tropical fish-poisoning plants. E. P. Clark. *J. Am. Chem. Soc.* **53**, 313–7 (1931); cf. *C. A.* **24**, 2752, 3534, 5927.—Complete details are given for the purification of *deguelin* (I), $C_{23}H_{22}O_6$, m. 171°, n_α 1.570, n_β 1.590, $n_\gamma > 1.739$; the extinction is inclined and the elongation is neg. This was prepd. from derris root and cubé root. It also occurs in the leaves of *Cracca (tephrosia) vogelii* and the roots of *Cracca (tephrosia) toxicaria*. Apparently I exists in nature in some form of combination, since it can be obtained only when the non-cryst. material is treated with an alkali. I showed no optical activity but it may have existed in the plant in an optically active state. I is oxidized with alk. $K_3Fe(CN)_6$ to *dehydrodeguelin* (II), $C_{23}H_{20}O_6$, m. 233°, n_α 1.635, n_β 1.687, $n_\gamma > 1.74$. II may also be obtained from crude I from derris root. Further oxidation of II in AcOH with CrO_3 gives *dehydrodeguelone*, $C_{23}H_{18}O_7$, bright yellow, m. 232 (cor.), n_α 1.505. II, EtOH-KOH and Zn dust, boiled 30 min., give 55% of *deguelic acid* (III), $C_{23}H_{24}O_8$, m. 189° (cor.), n_α 1.520, n_β 1.665, $n_\gamma > 1.74$; $FeCl_3$ gives a claret color. attempts to prep. an Ac deriv. by refluxing with Ac_2O and AcONa give II. These results indicate that I is a dimethoxylactone. C. J. West

Action of hydrogen sulfide on acid chlorides. II. Hydrogen sulfide and phthalyl chloride. Ludwik Szperl. *Roczniki Chem.* **10**, 652–6(656 French)(1930). cf. *C. A.* **25**, 503.—By action of H_2S on o-$C_6H_4(COCl)_2$ at 195–200° after elimination of HCl and o-$C_6H_4(CO_2)_2$ 2 compds were obtained: *o*-phthalyl sulfide (m. 113–4°) and *di-o-phthalyl disulfide*, $(C_6H_4)_2(COS)_4$, light-yellow needles, m. 330–1.5°. **III. Hydrogen sulfide and naphthalyl chloride.** Ludwik Szperl and Henryk Morawski *Ibid* 657–66(666 French).—By action of H_2S on $C_{10}H_6(COCl)_2$ at 100° without using a solvent a tarry mass is obtained. The same compd when heated in xylene or benzene to 80–6° gives *naphthalic acid thioanhydride*, $C_{12}H_6O_2S$, orange crystals, decompg. 200°. When heated energetically, they m. 205–6°. The compd. undergoes a hydrolysis under the action of the alkali and NH_4OH. J. Kučera

Sulfur compounds of terpenes. I. Action of sulfur on *d*-limonene and α-pinene. Akira Nakatsuchi. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 408–9(1930). *d*-Limonene (I) reacted readily with S, yielding $C_{10}H_{16}S$, or, if the double bond of the side chain was the point of attack, probably $S.CH_2.CMeCH.CH_2.CH_2.CMe:CH.CH_2$,

b. 104.5–5.5°, m. —26.79°, $[\alpha]_D^{25.1}$ —12.31°, $n_D^{27.6}$ 1.51534, $d_4^{27.6}$ 0.9948, M. R. 51.01. A mixt. of 180 g. of I and 46.8 g. S was heated at 160° for 28 hrs. and the reaction product fractionated under reduced pressure. The lower fractions, 28 g., consisted of *p*-cymene; higher ones were further fractionated and recrystd. from EtOH-Et_2O, crystals being obtained after 10 hrs. at —60°. $AuCl_3$ gave a cryst. addn. compd. α-Pinene (II) and S, under similar conditions, yielded a viscous mass consisting mostly of unchanged II, besides a polymerized product and a very small quantity of $C_{10}H_{16}S$. Whether this was identical with the reaction product from I was not detd. K. H. Engel

Autoxidation of piperitone in alkaline solution. W. Treibs. *Ber.* **63B**, 2423–8

(1930).—Various quinones in aq. or alc. alk. soln. absorb O and Harries observed that carvone (I), which, if considered as an unsatd. ketone, is closely related in chem. structure to these quinones, absorbs O when shaken in aq. MeOH with $Ba(OH)_2$, giving BaO_2 and a small amt. of a diketone. He assumed that a mol-oxide, formed by addn. of O, is the intermediate product. Pursuing this observation, T. has studied the power of a series of unsatd. ketones to absorb O in alk. alc. soln., as compared with quinones and phenols Unlike H., he used little or no H_2O. The O absorption was most rapid with the unsatd. cyclic ketones I, piperitone (II) and carvenone (III) and was accompanied by strong evolution of heat. Pulegone (IV), with a semicyclic double bond, slowly absorbed O, as did cyclohexenone and the bicyclic verbenone. Dihydrocarvone did not absorb O at all, benzalacetone absorbed it quite strongly, methylheptenone and mesityl oxide exceedingly weakly. The influence of various factors was first studied with the rapidly reacting I and II (0.1 *M* solns. in 40–60 cc. solvent). KOH at first accelerates the absorption somewhat more than NaOH but later slows up as compared with NaOH, so that the total absorption is about equally rapid with the 2 alkalies. The total amt. of absorbed O increases with the alkali concn. and with 1 mol. alkali to 1 mol. ketone the ketone reacts completely, taking up 1 mol. O_2. More alkali does not increase the amt. of O_2 taken up and does not appreciably accelerate the reaction. In more dil. soln. (0.1 mol. ketone in 500 cc.), 2 mols. O_2 is taken up and the reaction products contain lower fatty acids (probably resulting from autoxidation of the alc.). In Me_2CO absorption occurred only after addn. of alc., 1 mol. of the alc. sufficing to carry the reaction as far as in alc. alone. Different aliphatic alcs. (Me, Et, Pr, Bu, Am) had but little influence on the velocity of absorption, although a distinct acceleration was noted with increase in the length of the alc. chain. The action of $PhCH_2OH$ was weaker. The total absorption was practically independent of the nature of the alc. Under the same conditions (0.1 mol. in 40–60 cc. alc. with more than 0.1 mol. alkali), *p*-benzoquinone, phenanthrenequinone, β-naphthoquinone and orcinol, like I, II and III, absorbed 1 mol. O_2; *o*- and *p*-$C_6H_4(OH)_2$ used up 2 mols. O_2, $PhCH:CHCOMe$ and *m*-$C_6H_4(OH)_2$ only about 0.5 mol. In many cases, as with the very slowly reacting IV, a little $AuCl_3$ strongly accelerated the reaction until its velocity reached that with I. On *m*-$C_6H_4(OH)_2$, however, $AuCl_3$ exerted a strongly retarding influence. Pt and Pd salts were without effect. In every case, the absorption was accompanied by discoloration and formation, chiefly, of brown resins. In the acidified and filtered reaction mixt. and in the acid and neutral steam distillates, small amts. of superoxides could be detected by the liberation of I from KI. Steam distn. of the reaction product of II yielded thymol. More than 0.5 of the reaction product consisted of a resin, 30–5% of a mixt. of acids, the steam distillate of which dissolved to only a slight extent in alkali. The insol. portion (V) slowly dissolved in boiling alkali to form the salt of a cryst. odorless acid and is therefore undoubtedly a *lactone*. Analyses and equiv. wt. detns. by sapon. gave the formula $C_{10}H_{18}O_3$. V is stable toward Br and $KMnO_4$ and shows none of the reactions of keto acid lactones. The corresponding *HO acid* (VI) regenerates V above its m. p., on treatment with steam or on heating with dil. H_2SO_4. Autoxidation of II in alk. soln. therefore gives a γ- or δ-HO acid with a new (probably 5-membered) ring system With Na and alc. according to Semmler it gives a *glycol*, $C_{10}H_{20}O_2$, b_{13} 150–2°. $KMnO_4$ yields no keto acid but only unchanged VI or decompn. products. Attempts to esterify V with boiling alc. H_2SO_4 gave the esters of an unsatd. *acid* (VII) formed from VI by loss of H_2O. These esters are sapond. by short boiling with KOH in $PhCH_2OH$. The VII is identical with an acid accompanying V in the steam distillate of the autoxidation product of II. The residue of the steam distn. was a brown brittle tar whose soly. in alkali increased with the amt. of alkali used in the autoxidation; with the ratio ketone:alkali>1, it was almost completely alkali-sol. The sol. and insol. portions had the same compn. In the autoxidation of II, there is formed, along with the thymol, a phenol giving a green $FeCl_3$ reaction (probably thymohydroquinone). VII, $C_{10}H_{18}O_2$, b_{13} 140–5°, m. 57–9°, absorbs 2 atoms Br in $CHCl_3$. V, b. 246–8°, b_{13} 118–20°, d_{15}^{20} 1.010. VI, m. 113–4°; *K* and *Na salts*. *Me ester* of VII, b_{18} 94–5°, d_{15}^{20} 0.9450; *Et ester*, b_{14} 102–5°, d_{15}^{20} 0.9467.

C. A. R.

New condensation products of pernitrosocamphor with amines. PIETRO SACCARDI. *Ann. chim. applicata* **20**, 489-94(1930).—Using the discovery of Angeli and Rimini (*Gazz. chim. ital.* **25**, 406; **26**, 29–31) that pernitrosocamphor reacts readily with amines with elimination of water and N_2O_4, S. has prepd. several new products. *2-Camphoranaesthetine*, *p*-$R:NC_6H_4CO_2Et$ ($R = CH_2.C_8H_{14}.C:$) is formed by heating the components about 15 hrs. at 75–80° on a water bath. Recrystd. from EtOH, and de-

colorized with bone black, it m. 85°. It is very sol. in org. solvents, as well as in water. *2-Camphoranisidine*, *p*-R:NC_6H_4OMe, prepd. similarly, is a liquid, b. 246–9°, n^{18} 1.401. *2-Camphor-p-aminobenzoic acid*, *p*-R:$NC_6H_4CO_2H$, m. 238–9°, is slightly sol. in water, but more sol. in NaOH and $NaHCO_3$, and is more stable in alk. than in acid solns. *Pb-2-camphor-o-aminobenzoate*, prepd. by condensing pernitrosocamphor with anthranilic acid, and pptg. with $Pb(OAc)_2$, is a white powder. It was not possible to form a compd. with urethan or novocaine. A. W. CONTIERI

Catalytic oxidation of camphor. KUNIJIRO TAKEUCHI. *Bull. Inst. Phys. Chem. Research* (Tokyo) 9, 871–7(Abstracts 83(in English) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) 14, No. 271–3)(1930).—Camphor was air-oxidized in the vapor phase with the oxides of 5th and 6th group metals as catalysts. Maleic acid was one of the products, its max. % being about 10. J. B. AUSTIN

Camphoreins. II. The two camphoreins of phloroglucinol. VENANCIO DEULOFEU. *Anales asocn. quím. Argentina* 18, 164–71(1930); cf. *C. A.* 24, 3235.—α- and β-Phloroglucinol camphoreins can be converted one into the other. Both camphoreins and their salts have a quinone structure, shown by color. Acylic derivs. of both are colorless or slightly colored and have a lactone structure. E. M. SYMMES

X-ray investigations of optically active compounds. II. Biphenyl and some of its active and inactive derivatives. GEORGE L. CLARK AND LUCY W. PICKETT. *J. Am. Chem. Soc.* 53, 167–77(1931); cf. *C. A.* 23, 4942; 24, 2351.—Unique solns. of the crystal structure for Ph_2 and 5 of its derivs. have been detd by rotating and oscillating crystal methods. The results are summarized in the following table:

	System	Unit cell dimensions *a*	*b*	*c*		*n*	Space group	Symmetry of molecule
Biphenyl	Mono.	8.11	5.67	9.57	94°30′	2	C_{2h}^5	Center of symmetry
Bimesityl	Mono.	8.21	8.58	22.25	96°30′	4	C_{2h}^5	None
3,3′-Diaminobimesityl	Mono.	8.26	8.58	22.62	90° ± 30′	4	C_{2h}^5	None
Hexachloro biphenyl	Orth.	15.80	8.54	21.48	90°	8	Q_h^{16}	None
o-Tolidine	Orth.	6.50	7.48	23.62		4	Q^4	None
Diphenic acid	Orth.	13.80	11.90	14.12		8	Q_h^{13}	None

The $2C_6H_5$ rings in the Ph_2 mol. are in prolongation of each other rather than doubled over on each other. The rings probably are not flat. It is probable that the C atoms are in staggered or puckered rings, a conclusion reached by Hengstenberg and Mark. The fact that the mols. of bimesityl and $(Cl_3C_6H_2)_2$ possess no symmetry leads to the conclusion that the 2 rings are either bent or turned at an angle to each other in these compds. The mols. in all cases lie with their length parallel or at a slight tilt to the *c* axis. The rings of C atoms are in each case probably staggered and have a thickness which is constantly 4.3 for the derivs. and 4.1 for Ph_2 itself. The width across the ring is 5.6 for Ph_2, 7.9 for $(Cl_3C_6H_2)_2$ and 8.1 for bimesityl and its di-NH_2 deriv. The resp. lengths for these compds are 9.5, 10.75, 11.1 and 11.3. The facts that the mols. are asym. and that they occupy the spaces given above lead to the conclusion that the 2 rings are in planes turned from each other at an angle of not greater than 45° in the 2,2′,6,6′-deriv. of Ph_2, while the rings in Ph_2 itself are coplanar. C. J. WEST

Stereochemistry of diphenylbenzenes. Meso and racemic 2,5-di(3-bromo-2,4,6-trimethylphenyl)-3,6-dibromohydroquinones and the corresponding quinones. XII. P. R. SHILDNECK AND ROGER ADAMS. *J. Am. Chem. Soc.* 53, 343–52(1931); cf. Steele and A., *C. A.* 25, 105.—O:C_6H_4:O and 1,3,5-$C_6H_3Me_3$ with $AlCl_3$, below 5°, give *2,5-dimesitylhydroquinone*, m. 225–6° (all m. p. cor.). With Br in $CHCl_3$ this yields 2 stereoisomeric *2,5-di(3-bromo-2,4,6-trimethylphenyl)-3,6-dibromohydroquinones* (I and II), m. 334–5° and 294–5°, sepd. by their differing soly. in Me_2CO, the ratio at room temp. being about 50:1. The *acetate* from I m. 285–6°; from II, 237–8°; the latter is 8–10 times more sol. in boiling C_5H_5N than is the former. Oxidation of I and II with O:C_6H_4:O gives 2 forms of *2,5-di(3-bromo-2,4,6-trimethylphenyl)-3,6-dibromoquinones* (III and IV), orange, m. 295–6° (decompn.) and 284–5° (decompn.); reduction gives I and II. Oxidation of III and IV gives with alk. H_2O_2 a *monobromomesitylcarboxylic acid*, m. 168°, also obtained by brominating the parent acid. Further bromination of I and II gives the same *2,5-di(3,5-dibromo-2,4,6-trimethylphenyl)-3,6-dibromohydroquinone*, m. 395–8° (block); *diacetate*, m. 297°; oxidation gives the corresponding *quinone*, orange, m. 390–3° (block). Oxidation of the quinone gives *dibromomesitylcarboxylic acid*, m. 210–1°. C. J. W.

Stereochemistry of *N*-phenylpyrroles. Preparation and resolution of *N*-2-carboxyphenyl-2,5-dimethyl-3-carboxypyrrole. XIII. L. H. Bock and Roger Adams. *J. Am. Chem. Soc.* **53**, 374–6(1931); cf. Shildneck and A., preceding abstr.—Condensation of 3-carbethoxy-2,5-hexanedione and anthranilic acid in abs. EtOH and sapon. give *N-2-carboxyphenyl-2,5-dimethyl-3-carboxypyrrole* (I), m. 224.5–5.5°. Resolution was effected by means of the brucine salt. *l*-I, m. 202–3°, $[\alpha]_D^{20}$ —27.2° (0.1349 g. in 15 cc. abs. EtOH); *monobrucine salt*, m. 231–2° (decompn.), $[\alpha]_D^{20}$ —44.9° (0.1137 g. in 15 cc. $CHCl_3$). *d*-I, m. 202–4°, $[\alpha]_D^{20}$ 27° (0.1753 g. in 15 cc. abs. EtOH); *brucine salt*, m. 175–80° (decompn.), $[\alpha]_D^{20}$ 13.5° (0.1551 g. in 15 cc. $CHCl_3$). The active forms do not racemize upon boiling for 8 hrs. in EtOH; they are, however, completely racemized upon boiling 24 hrs. in 0.1 *N* NaOH. C. J. West

Action of organic magnesium compounds on α-oxido ketones and esters. E. P. Kohler, N. K. Richtmyer and W. F. Hester. *J. Am. Chem. Soc.* **53**, 205–21(1931).—When org. Mg compds. react with α-oxido ketones, they combine with the CO group only. By operating at a low temp. and decompg. the product immediately, it is possible to secure the corresponding oxidocarbinol; otherwise the unstable Mg derivs. decomp. spontaneously into Mg derivs. of aldehydes and ketones, which may subsequently be transformed into tert. alcs. Org. Mg derivs. first transform α-oxido esters into α-oxido ketones; the final products are therefore the same as those obtained with these ketones. Benzalacetophenone oxide and EtMgBr at room temp. give 66% of Et_2PhCOH, b_{20} 110–2°; PhMgBr gives 70% of Ph_3COH. If the reaction is carried out at —10°, there results *α-phenyl-β-(diphenylhydroxymethyl)ethylene oxide*, O.CHPh.CHCPh$_2$OH (I), m. 129–30°; excess PhMgBr does not react with I at —10° but at room temp. Ph_3COH was isolated; I is unchanged by heating 1 hr. at 150°, does not react with warm Ac_2O and is unchanged by concd. NH_4OH, with or without MeOH. I in abs. MeOH contg. concd. HCl, boiled 1 hr., gives *α,α,γ-triphenyl-α,β-dihydroxy-γ-methoxypropane* (II), m. 154–5°; by-products are BzH and Ph_2CHCHO; oxidation of II gives BzOMe and BzPh. Benzalacetophenone dibromide and MeONa at 0° give the *di-Me acetal* of *α-hydroxy-β-methoxy-β-phenylpropiophenone*, m. 122°; hydrolysis, followed by reaction with PhMgBr, gives quant. II. Isomerization of I with KOH gives *α,α-diphenyl-β-(hydroxybenzyl)ethylene oxide*, PhCH(OH)CH.CPh$_2$.O, m. 103° and unchanged at 150°, oxidation with CrO_3 in AcOH gives diphenylethylene oxide; PhMgBr gives an oil, contg. Ph_2, Ph_3CHCHO and benzohydrol; MeMgI gives BzH, Ph_2CHCHO and a *compd.*, m. 128°, possibly PhCH(OH)COCHPh$_2$. Autoxidation gives BzH and a *peroxide*, $C_{21}H_{18}O_4$, m. about 160° (decompn.); thermal decompn. of this peroxide gives BzH, BzPh and HCO_2H; MeMgI gives diphenylmethylglycol, m. 94–5°. $BzCBr_2Bz$ and PhMgBr give *α-bromo-β,β diphenyl-β-hydroxypropiophenone*, $Ph_2C(OH)CHBrBz$, m. 180° (decompn.); MeONa gives nearly quant. *benzoyldiphenylethylene oxide* (III), m. 124–5°; with PhMgBr III gives Ph_3COH and Ph_2CHCHO; EtMgI also gives Ph_2CHCHO. Diphenylglycidic ester (IV), which was not obtained pure, and PhMgBr give Ph_3COH. Et diphenylglyoxylate m. 37°; *phenylhydrazone*, yellow, m. 99–100°; oxidation with H_2O_2 gives Ph_2CHCO_2H; sapon. gives $Ph_2CHCOCO_2Et$, whose phenylhydrazone m. 210° (slowly heated) or 245° (on block); the *Me ester* b_8 175°, m. 75°. The ester and PhMgBr at 0° give *Et α,β,β-triphenyl-α-hydroxypropionate*, m. 118–20°; if the reaction is carried out at room temp. for several days or is boiled 3–4 hrs., the products are *α,β,β-triphenyl-α-hydroxypropiophenone*, m. 123°, and *α,α,β,γ,γ-pentaphenyl-α,β-dihydroxypropane*, m. 190° (decompn.), sepd. by the greater soly. of the former in petr. ether. The crude IV, on distn. with steam, gives the *compd.* $Ph_2C(OH)CH(OH)CO_2Et$, m. 130°; the corresponding *Me ester* m. 130–1°. C. J. West

Derivatives of fluoran. I. The isomeric dihydroxyfluorans. Mieczyslaw Dominikiewicz. *Roczniki Chem.* **10**, 667–85(685 German)(1930).—The synthesis is described of 1,6-, 2,6- and 4,6-dihydroxyfluorans which were obtained in 1919 by D. and recently synthesized by Ghattak and Dutt (*C. A.* **24**, 101) in another way. In addn. there was isolated from the fluorescein fusion about 15% of 1,8-dihydroxyfluoran which represents an *o*-quinoid isomeric fluorescein. The 2,4,5,7-Me_4 deriv. of this dihydroxyfluoran had already been obtained from *m*-xylorcinol and $C_6H_4(CO)_2O$ (*Sprawozd. Tow. Nauk. Warszawa* **1918** [3], 280). Fluorescein, hydroquinonephthalein and the 4 above-mentioned dihydroxyfluorans were subjected to nitration and thereby were obtained dinitro derivs. which on reduction gave the corresponding diamino derivs. The dinitro derivs. behave as acid dyes of orange color whereas the diamino compds. are not basic dyes. The only exception is 3,6-diaminohydroquinonephthalein which must

be regarded as 2,7-dihydroxyrhodamine. The constitution which is given to this compd. is not doubtful and is at the same time determinative, for the constitution of other dihydroxyfluorans. Samples of colorations of Na salts of the resp. dyes are given.
J. KUČERA

Occurrence of free disubstituted methyl radicals in chemical reactions. ERNST BERGMANN AND SHIN-ICHIRO FUJISE. *Ann.* **483**, 65–80(1930).—Prolonged exposure of a mixt. of Ph_2CO and $(p\text{-}MeC_6H_4)_2CH_2$ to sunlight in quartz vessels results in the formation of benzopinacol (I), also formed from $(p\text{-}Me_2NC_6H_4)_2CH_2$ (II) and Ph_2CO in dioxane. II and $PhCOC_6H_4Ph$ in C_6H_6 in a N atm., exposed to sunlight for 2 months, give a *4,4'-diphenylbenzopinacol*, m. 212°. $(p\text{-}MeOC_6H_4)_2CH_2$ and Ph_2CO in C_6H_6, after exposure to light for 9 weeks, give a mixt. of I, *tetra-p-anisylethane*, m. 189–90°, and *α,α-diphenyl-β,β-di-p-anisylethyl alc.*, m. 182–3°, dehydrated by boiling AcCl to *α,α-diphenyl-β,β-di-p-anisylethylene*, m. 154–5°. The production of these compds. is readily explained by the intermediate formation of the radicals $CH(C_6H_4OMe)_2$ and CPh_2OH, which either add or dimerize. Ph_2CO and Ph_2CHOMe give, after 3 months in the light, a mixt. of I and its *di-Me ether*, m. 157–9°. The *mono-Me ether*, m. 127–8°, is not formed, but is synthesized from PhMgBr and *Me α-methoxydiphenylacetate*, b_{27} 199–200°. *Di-p-anisylmethyl Me ether*, b_{15} 218–9°, m. 35–7°, undergoes very slow scission when treated with Na. $[(PhCH_2)_2CHS]_2$, heated with Cu-bronze, gives a mixt. of $(PhCH_2)_2CH_2$ and $PhCH{:}CHCH_2Ph$; the intermediate free radical, $(PhCH_2)_2CH$, undergoes disproportionation into $(PhCH_2)_2CH_2$ and $(PhCH_2)_2C$: the last named radical is rendered stable by the migration of a H atom, whereby the propene results Distn. of the reaction product $(PhMeCHS)_2$, from PhAc and $(NH_4)_2S$, furnishes PhEt and $PhCH{:}CH_2$; a small amt. of *di-α-phenylethyl sulfone* (?), m. 167–9°, is also formed. These results are explained by disproportionation of free $PhCH_2CH_2$ radicals. When 9,9'-difluorenyl disulfide is heated with Cu-bronze over a free flame in an atm. of N, fluorene, diphenylenephenanthrene and a small amt. of *α,β*-di(diphenylene)ethane are produced. The 9-methylenefluorene described by Manchot and Krische (*Ann.* **337**, 170(1904)) is impure fluorene.
C. J. WEST

Triphenylmethyl chloride and silver fulminate. HEINRICH WIELAND AND BRUNO ROSENFELD. *Ann.* **484**, 236–45(1930).—Ph_3Cl and $C{:}NOAg$ in abs. C_6H_6 give *triphenylmethyl nitrile oxide* (I), $Ph_3CC{:}N{:}O$, m. 153–4°; concd. H_2SO_4 gives a red color, changing to deep yellow and on warming to green. During the reaction a double salt of AgCl and Ph_3CCl, deep yellow, was observed. Heating I with EtOH-HCl gives quant. *triphenylacethydroxamyl chloride*, $Ph_3CC(:NOH)Cl$, m. 178–80° (decompn.); heating at 190° for 5 min. again gives I; MeOH-KOH gives the *Me ester*, m. 204°; the free acid m. 165–7°. Reduction of I with Zn and EtOH-HCl gives *triphenylmethyl cyanide*, m. 129°. I and PhMgBr give *benzopinacolin oxime* (II), m. 210°, whose Bz deriv. m. 175°. The Beckmann rearrangement with concd. H_2SO_4 gives Ph_3COH and $BzNH_2$. II and $NaNO_2$ in AcOH give the *nitrimine*, m. 160° (decompn.); heating at 160–80° gives NO, PhCN and Ph_3COH; reduction with Na-Hg gives *benzopinacolin hydrazone* (III), m. 189°; *Me_2CO condensation product*, m. 144–5°. III and HgO in $C_6H_4Me_2$ give $Ph_2C{:}CPh_2$. *Benzopinacolin imine*, m. 165°, results from the nitrimine, $SnCl_2$ and HCl in 35% EtOH-HCl. Ph_3CCl (11.5 g.) and 6 g. $C{:}NOAg$ in 40 cc. C_6H_6 give 1.6 g. I, insol. in Et_2O, and 1.5 g. of the *triphenylmethyl ether* of triphenylacethydroxamyl chloride, $C_{39}H_{30}ONCl$, m. 174–5°; reduction gives Ph_3CCN and Ph_3CH.
C. J. WEST

The reaction between phenylmagnesium bromide and carbon dioxide at elevated temperatures. HENRY GILMAN AND NINA B. ST. JOHN. *Rec. trav. chim.* **49**, 1172–7 (1930).—Gilman, Fothergill and Parker (*C. A.* **23**, 4464) have given directions for the prepn. of tertiary alcs. from acid halides; the present paper deals with the prepn. of these compds. from CO_2 and RMgX compds. In the latter reaction small quantities of $(Ph_3C)_2O_2$ are always formed on carrying out the reaction with PhMgBr (cf. Meyer and Tögel, *Ann.* **347**, 55(1906); Schroeter, *Ber.* **36**, 3005(1903)) and the supposition is put forward that this compd. is formed by the oxidizing action of ether peroxide which almost invariably is present in small quantities in Et_2O. In support of this supposition are the facts that old ether gives a higher yield of the peroxide than fresh ether and that no peroxide was obtained when the PhMgBr was prepd. in PhOEt or was suspended in PhBr. The $(Ph_3C)_2O_2$ may, however, also be formed by atm. oxidation of a Ph_3C halide, the formation of which is possible according to the reaction: $Ph_3COH + MgBr_2 \longrightarrow Ph_3CBr + MgBrOH$, the Ph_3COH being formed by hydrolysis of $Ph_3COMgBr$, only traces of water being necessary in view of the high mol. wt. of the Ph_3C compds. The 2nd explanation is, however, not very probable in view of the fact that the yield of the peroxide increased on using a soln. of PhMgBr which was prepd. with such an excess

of Mg that the yield of PhMgBr was almost theoretical and which, therefore, contained hardly any $MgBr_2$. On carrying out the reaction between CO_2 and PhMgBr in PhBr a small quantity of *p*-$PhC_6H_4CO_2H$ was isolated, the formation of which indicates the intermediate formation of Ph and phenylene radicals. On heating $Ph_3COMgBr$ in an ether-benzene mixt. during 20 hrs. a 73% yield of Ph_3CH was obtained; the $Ph_3COMgBr$ was prepd. from the carbinol and EtMgBr and, if an excess of the latter reagent was used, $CHPh_3$ was not formed at all. From Ph_2CO and PhMgBr 92% of Ph_3CH was obtained and Ph_2CO may be obtained from PhMgBr and BzCl in 50% yield by the rapid addn. of the Grignard reagent to the BzCl. On prepg. Ph_3COH from PhMgBr and CO_2 the following results were obtained in which the time necessary for the completion of the reaction is given also: in ether, 6 hrs. and 36.9%; in benzene, 16 hrs. and 44.5%; in benzene, 10 hrs. and 46%; in toluene, 4 hrs. and 42%; in *p*-cymene, 9 hrs. and 46.8%. C. F. VAN DUIN

Hemi-ethers of benzopinacol. LUDWIG SCHUSTER. *Ber.* **63B**, 2397–9(1930); cf. Löwenbein and S., *C. A.* **24**, 5296.—The monoalkyl and -aryl ethers of $Ph_2C(OH)COPh$ with PhMgBr give in good yield the cryst. hemi-ethers, $Ph_2C(OR)C(OH)Ph_2$, of benzopinacol which with hot HBr-AcOH rearrange almost instantaneously and quantitatively into the alc. ROH and β-benzopinacolin. *Phenylbenzoin mono-Ph ether* (10 g. from 17.5 g. Ph_2CMeBr and 1 equiv. PhOH gently warmed on the H_2O bath), m. 134.5°. *Benzopinacol mono-Me ether* (88% from $Ph_2C(OMe)COPh$ and PhMgBr), m. 182.5°. *Mono-Et ether* (75% from $Ph_2C(OEt)COPh$). *Mono-Ph ether* (66%), m. 219°. C. A. R.

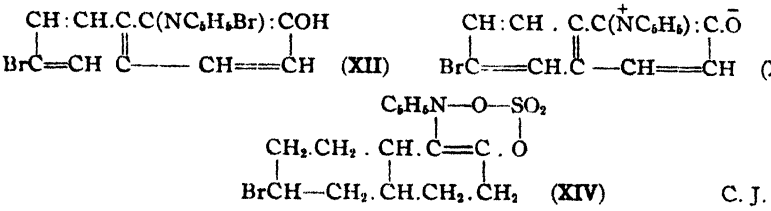
Valence tautomerism of unsaturated systems. G. WITTIG AND W. WIEMER. *Ann.* **483**, 144–56(1930).—1,5-$C_{10}H_8Bz_2$, m. 185–6°; *1,6-isomer*, m. 175–6°; *2,6-isomer*, m. 184–6°; *2,7-isomer*, m. 171–2°. With PhMgBr the 1,5-isomer gives *1,5-bis(diphenylhydroxymethyl)naphthalene*, m. 280° (decompn.); concd. H_2SO_4 gives a red soln.; HCl gas in dioxane gives the *dichloride*, m. 250–1°; a dry $C_6H_4Me_2$ suspension, shaken with Naturkupfer C in a N atm. for several days, gives a red filtrate with a sharp absorption band at about 470 mμ. The soln. contained a considerable amt. of the HO deriv., so that the radical could not be obtained pure; shaking with O decolorizes the soln. after several hrs. *2,6-Bis(diphenylhydroxymethyl)naphthalene*, m. 279–81° (decompn.); concd. H_2SO_4 gives a deep red color; *dichloride*, m. 250–3°; Cu gives *2,6-bis(diphenylmethylene)naphthalene*, black glistening crystals; the $C_6H_4Me_2$ soln. is red with an absorption band at 500 mμ; $PhICl_2$ gives the dichloride. (*p*-$BzC_6H_4CH_2)_2$, m. 174–6°, with Br in $PhNO_2$, heated 15 min. to boiling, splits off HBr and gives *p,p'-dibenzoylstilbene*, m. 234–5°; with PhMgBr there results *p,p'-bis(diphenylhydroxymethyl)stilbene*, m. 208–12°; *dichloride*, m. 213–6°; concd. H_2SO_4 gives a blue color and NaOH gives the original glycol. With Cu there results *p,p'-bis(diphenylmethylene)stilbene*, greenish crystals, giving a blue-violet color; the deep blue C_6H_6 or $C_6H_4Me_2$ soln. shows an absorption band at 630 mμ. $PhICl_2$ gives the dichloride. O_2 decolorizes the soln. of the radical momentarily, giving a yellow oxidation product, m. 150–5°. The solid unsatd. radical decomps. in about 20 min. on standing in the air. C. J. WEST

Method of preparing β-naphthalenic derivatives. A. BARBOT. *Bull. soc. chim.* [4], **47**, 1314–23(1930).—The Friedel-Crafts reaction with tetralin results exclusively in substitution in the β-position, and also, by the use of $AlBr_3$, in place of $AlCl_3$ the yields can be so increased as to make the reaction serviceable. *β-Methyltetrahydronaphthalene* (I) (cf. *C. A.* **18**, 2515). MeBr was passed through a hollow agitator into 12 g. $AlBr_3$ in 400 g. of dry $C_{10}H_{12}$ at 140–50° for 2 days, until 75.5 g. was absorbed. The product was cooled, decompd. with H_2O, washed, dried and fractionated. Sixteen g. of I (14% yield), b_{12} 99–101°, was obtained in addn. to 170 g. $C_{10}H_{12}$ and 35 g. of a mixt. of octahydrophenanthrene and octahydroanthracene. The addn. of 327 g. of EtBr to 40 g. of $AlBr_3$ in 792 g. of $C_{10}H_{12}$ at 110–20° gave 28% of *β-Et homolog* (II) of I, b_{10} 121–2°, and 80 g. of a substance (IX), b_9 219°. The yield with $AlCl_3$ was 3.5%. *iso-Pr compd.* (III), b_{13} 124–6° (37% yield), was prepd. in a similar fashion and was accompanied by IX. *β-tert-Bu compd.* (IV), b_{11} 129°, gave a 70% yield with $AlBr_3$ against 24.5% with $AlCl_3$. By the action of AcCl on $C_{10}H_{12}$ with $AlCl_3$ as catalyst *Me β-tetrahydronaphthyl ketone* (V), b_{16} 161° (*semicarbazone*, m. 257–8°), was formed with 90% yields B. prepd. in the same way the following *β-tetrahydronaphthyl ketones: Et* (VI), b_{12} 163–4°, d_{23}^{23} 1.033, n_D^{23} 1.550, M_D 58, calcd. 56.7 (*semicarbasone*, m. 224–5°), yield 46%; *Pr* (VII), b_{18} 176–9°, d_{23}^{23} 1.030, n_D^{23} 1.5460, M_D 62.1, calcd. 61.3 (*semicarbazone*, m. 172–3°), yield 58%; *iso-Pr* (VIII), b_{11} 164–7°, d_{23}^{23} 1.025, n_D^{23} 1.5444, M_D 62.2, calcd. 61.3, yield 54%. When acted upon by CH_2O and HCl in the presence of $ZnCl_2$, or by CH_3OCH_2Cl in the presence of $SnCl_4$, $C_{10}H_{12}$ gives a mixt. of α- and β-$C_{10}H_{11}CH_2Cl$. By heating with S, the tetra-

hydronaphthalenic derivs. can be dehydrogenated simply and with satisfying yields. For quantities of about 100 g., the substance (1 mol.) is introduced together with 2 atoms of S into the inner chamber of a thermostatic jacket which is heated by crude $NO_2C_7H_7$ at 215–20°. H_2S begins to come off at 190° and the evolution is rapid at 200°. After heating for 2 hrs. the crude product is distd. and the distillate is purified by boiling with NaOH. The following *β-alkyl(acyl)naphthalenes* were prepd. in this manner: *Me*, from I in 75% yield, b_{16} 110–2° (*picrate*, m. 115°); *Et*, b_{10} 117–8° (*picrate*, m. 72–3°), from II in 69% yield; *iso-Pr*, 72.5% from III, b_{14} 129–30° (*picrate*, m. 89–90°); *tert-Bu*, 70% from IV (*picrate*, m. 102–3°); *Ac*, in 71% yield from V, b_{17} 171–3°, m. 52° (*oxime*, m. 142°; *semicarbazone*, m. 234–5°); *EtCO*, 72% from VI, b_{18} 181–3°, m. 58–9° (*oxime*, m. 131–2°; *semicarbazone*, m. 190–1°); *PrCO*, 72% from VII, b_{16} 184–5°, m. 52° (*oxime*, 86–9°); *iso-PrCO*, from VIII in 71.4% yield, b_{18} 180–1° (*oxime*, m. 121–2°). By the dehydrogenation of β-tetrahydronaphthyl Ph ketone 73% of *β-naphthyl Ph ketone*, m. 81°, was obtained, identical with the product of the CrO_3 oxidation of β-$C_{10}H_7CH_2Ph$. By the action of HCl and $AlCl_3$, $C_{10}H_{12}$ may form $PhCH_2CH_2CH_2CH_2Cl$, condensing with $C_{10}H_{12}$ to give the dimer $PhCH_2CH_2CH_2CH_2C_{10}H_{11}$ (IX), which in the presence of $AlCl_3$, on splitting out C_6H_6 and joining the end of the chain to the tetralin nucleus in the 5- or 7-position, would form octahydrophenanthrene or octahydroanthracene, resp. *α,δ-Diphenylbutane* (X) (cf. *C. A.* **15**, 525). Sixty-six g. of $C_{10}H_{12}$ was heated to boiling with 234 g. of dry C_6H_6 and 10 g. $AlBr_3$ or $AlCl_3$ for 8 hrs. On cooling, washing with H_2O, distn. and recovery of 224 g. C_6H_6 and 52 g. of $C_{10}H_{12}$ there was obtained 14 g. of X, m. 82°. C. R. ADDINALL

Interaction of tertiary butyl chloride and naphthalene. WM. GUMP. *J. Am. Chem. Soc.* **53**, 380–1(1931).—The so-called α,β- and α,α-$(C_{10}H_7)_2$ of Wegscheider (*Monatsh.* **5**, 238(1884)) are actually 2 isomeric *di-tert-butylnaphthalenes*, b. 319°, m. 82–3°, and b. 320°, m. 145–6°, sepd. by crystn. from MeOH or EtOH. The position of the Bu groups could not be established by oxidation with dil. HNO_3. C. J. WEST

Reduction of naphthalene by alkali metals in liquid ammonia. CHARLES B. WOOSTER AND FRANK B. SMITH. *J. Am. Chem. Soc.* **53**, 179–87(1931).—The reduction of $C_{10}H_8$ with Na in liquid NH_3 takes place through the intermediate formation of a 1,2,3,4-tetra-Na addn. product, which is approx. 75% ammonolyzed even in soln. at −33.5°. The reaction with K apparently follows essentially the same course as that with Na. These facts confirm the mechanism derived by extending to this reaction the theory proposed by Willstätter, Seitz and Bumm to explain reductions of org. compds. with Na-Hg and H_2O. Certain facts have been pointed out which suggest a similar mechanism for the reduction of other aromatic compds. by Na in liquid NH_3 and for the reduction of $C_{10}H_8$ by Na in EtOH. C. J. WEST

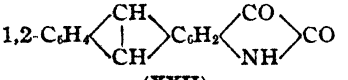


The velocity of intramolecular transformation of β-naphthylacetylchloroamine. A. P. J. HOOGEVEEN. *Rec. trav. chim.* **49**, 1093–106(1930); cf. *C. A.* **24**, 4289.—Contrary to the results obtained by Blanksma (*Verslag. Akad. Wetenschappen Amsterdam* 159, June 28, 1902 and 378, Oct. 25, 1902; *Rec. trav. chim.* **21**, 290(1903)) and Fontein (*C. A.* **22**, 2553) in the detn. of the velocity of transformation of PhNClAc and other arylacylhalogenoamines, the curves showing the relationship between the compn. of the solvent and the velocity of transformation of α-$C_{10}H_7NClAc$ show a min. at about 50% EtOH or AcOH. This min. was obtained with different concns. of HCl, while it was impossible to detect any connection between the amt. of HCl and the reaction velocity; on the other hand, Blanksma had found with the arylacylhalogenoamines that the reaction velocity was proportional to the square of the quantity of HCl present. Therefore these investigations in the $C_{10}H_8$ series were continued with the β-compd. which was prepd. from the dil. AcOH soln. of β-$C_{10}H_7NHAc$ and bleaching powder soln. and recrystn. of the crude product from petr. ether, b. 40–50°, m. 80°; purity, as detd. by titration with KI, 94%. The intramol. transformation of this compd. gives 1,2-$ClC_{10}H_6NHAc$, m. 149–150°, which on sapon. gave 1,2-$ClC_{10}H_6NH_2$, m. 60° (*Ber.* **20**, 1990(1887)). This is in agreement with the fact that in similar cases with β-$C_{10}H_7$ derivs., products are obtained with substituents in position 1 (cf. Fischer and Hepp, *Ber.* **20**, 2471(1887) for β-$C_{10}H_7NEtNO_2$, Gilbert and others, *J. Chem. Soc.* **115**, 1141(1919) for the corresponding Me compd. and Bamberger, *Ber.* **30**, 1262(1897) for β-$C_{10}H_7NHNO_2$). According to Franzen and Stäuble (*C. A.* **16**, 1945) the positions 1, 3 and 6 may be occupied in such transformations, the position 1 being favored. The 94% prepn. of the chloroamine was used for all the measurements, which were carried out at 25°, the following results being obtained: *In 0.1 N HCl: K* in water 0.0054; 5% EtOH 0.0046; 10% EtOH 0.0040; 20% EtOH 0.0039; 30% EtOH 0.0045; 40% EtOH 0.0070; 50% EtOH 0.0124; 60% EtOH 0.0233; 70% EtOH 0.0500. *In 0.2 N HCl: K* in water 0.0119; 10% EtOH 0.0094; 20% EtOH 0.0102; 30% EtOH 0.0147;

40% EtOH 0.0245; 50% EtOH 0.0423; 60% EtOH 0.0808; 70% EtOH 0.1670. From 30% EtOH upward the ratio of the reaction velocities on doubling the concn of the HCl is about 3.4 and in smaller concns. 2.1–2.6. The same ratio, 3.5, was found in 50% EtOH for 0.1 and 0.05 N HCl, the reaction velocity in the latter case being 0.0035. *In 0.1 N HCl: K* in 10% AcOH, 0.0039; 20% AcOH 0.0038; 30% AcOH 0.0056; 40% AcOH 0.0092; 50% AcOH 0.0185; 60% AcOH 0.0489; 70% AcOH 0.1832. All these reaction consts. were calcd. by means of the formula for a monomol. reaction. From these results the following conclusions were drawn: (1) The reaction velocity in mixts. of EtOH and water is about 1.5 times as great as that of PhNClAc and α-$C_{10}H_7$NClAc in mixts. with equal % of EtOH; (2) the reaction velocity is high in mixts. of water and EtOH or AcOH with high concns. of the org. compd. and it decreases on addn. of water; (3) the reaction velocity is lowest in mixts. contg. from 10 to 20% EtOH or AcOH; (4) in H_2O the reaction velocity again increases slightly; (5) the various peculiar phenomena, which were observed with α-$C_{10}H_7$NClAc (cf. above), are also observed, although to a much smaller extent, with β-$C_{10}H_7$NClAc in mixts. contg. 10% and 20% AcOH or EtOH. The curves representing the connection between the compn. of the solvent and the reaction velocity are almost identical with those obtained with phenylacylhalogenoamines (cf. Blanksma, *Rec. trav. chim.* **21**, 336(1902); **22**, 290 (1903); Fontein, *C. A.* **22**, 2553). C. F. VAN DUIN

Aromatic and hydroaromatic halogen compounds from β-naphthol. Consideration of the course of substitution reactions. K. FRIES AND K. SCHIMMELSCHMIDT. *Ann.* **484**, 245–300(1930); cf. *C. A.* **19**, 59.—2,3-$HOC_{10}H_6CO_2H$ and Br in AcOH, heated 1 hr. on the water bath, give 80% of the *1,5,6-tri-Br deriv.*, light yellow, m. 320°, very resistant to further bromination; oxidation with HNO_3 gives *3,4-dibromophthalic acid*, m. 196°; *anhydride*, m. 148.5°. If the above bromination is carried out in the presence of AcONa, 94 g. acid gives 180 g. of *1,1,3,3-tetrabromo-2-keto-4-acetoxynaphthalene 1,2,3,4-tetrahydride* (I), m. 140°, decomps. 155°, liberates I from KI, gives with Zn 1,3,2-$Br_2C_{10}H_5OH$ and with $SnCl_2$ in concd. HCl *1,3-dibromo-2-hydroxy-4-acetoxynaphthalene*, m. 148°; Ac deriv., m. 122°; the di-HO compd. could not be prepd. by acid or alk. hydrolysis; with $SnCl_2$ and 2 *N* NaOH there results 40% of *1,1'-dibromo-2,4,2',4'-tetrahydroxy-3,3'-dinaphthyl*, m. 242° (decompn.); *tetra-Ac deriv.*, m. 222–3°. I with HBr-AcOH gives 1,3 6,2,4-$Br_2C_{10}H_3(OH)_3$, m. 186°. I and Zn in AcOH give *1,3,2-dibromonaphthol* (II), m. 75°; *Ac compd.*, m. 102°. With fuming HNO_3 in AcOH II gives *1,3-dibromo-1-nitro-2-ketonaphthalene 1,2-dihydride*, yellow, m. 98° (decompn.); in boiling C_6H_6 there results 3-bromo-1,2-naphthoquinone, m. 179°; $PhNH_2$ in EtOH gives 50% *3-bromo-2-hydroxy-1,4-naphthoquinonanil*, dark brown, m. 233°, also obtained from the 3,4-Br_2 deriv. and $PhNH_2$ in 80% yield; excess $PhNH_2$ gives the 2-anilino deriv Reduction of the quinone with H_2SO_3 in AcOH gives *1,2-dihydroxy-3-bromonaphthalene*, m. 117°; *di-Ac deriv.*, m. 160°. II, Br, AcONa and AcOH give *1,1,3-tribromo-2-ketonaphthalene 1,2-dihydride*, yellow, m. 102–5°; in HBr-AcOH there are formed II and 1,3,6,2-$Br_3C_{10}H_4OH$. II, Sn, concd. HCl and EtOH, boiled 8 hrs., give *3-bromo-2-naphthol*, m. 83°; *Ac deriv.*, m. 94°; *Me ether*, m. 77–8°; the Grignard reagent from the ether and CO_2 give *2-methoxynaphthalene-3-carboxylic acid*, m. 131°, thus establishing the 3-position of the Br. 4,2-$BrC_{10}H_6NH_2$ (*Ac deriv.*, m. 189.5°) in H_2SO_4 gives with HNO_2 *4-bromo-2-naphthol*, m. 122°. *4-Bromo-2-amino-1-naphthol*, m. 128°; *di-Ac deriv.*, m. 231°; with HNO_3-AcOH there results 90% of *4-bromo-1,2-naphthoquinone*, red, m. 154°, which gradually splits off HBr, giving a yellow-green compd.; heating on the water bath gives a black resin; heating with 20 parts EtOH and 1 part concd. HCl gives 80% of *2-hydroxy-1,2-naphthoquinone*, m. 189°; $PhNH_2$ in EtOH gives the anil, m. 265° when pptd. from dil. NaOH or 244° when crystd. from EtOH or C_6H_6; *o*-$C_6H_4(NH_2)_2$ gives the *quinoxaline*, yellow, m. 186°. 1,6,2-$Br_2C_{10}H_5OH$ and HNO_3 in AcOH give *1,6-dibromo-1-nitro-2-ketonaphthalene 1,2-dihydride*, yellow, m. 100° (decompn.); heating in C_6H_6 gives *6-bromo-1,2-naphthoquinone* (III), m. 168° (decompn.). 2-$C_{10}H_7OH$, Br, AcOH and AcONa give 72% of *1,1,3,6-tetrabromo-2-ketonaphthalene 1,2-dihydride*, golden yellow, m. 168° (decompn.); reduction with $SnCl_2$-AcOH gives 95% of 1,3,6,2-$Br_3C_{10}H_4OH$ (IV), m. 132°, also obtained by bromination of II; *Ac deriv.*, m. 152°; reduction with Sn and HCl in EtOH gives 3,6,2-$Br_2C_{10}H_5OH$, m. 127° (*Ac deriv.*, m. 127°). IV and HNO_3 in AcOH give *1,3,6-tribromo-1-nitro-2-ketonaphthalene 1,2-dihydride*, canary-yellow, transformed at 80° or better by heating in C_6H_6 into *3,6-dibromo-1,2-naphthoquinone*, red, m. 176°, which also results from the 3,4,6-Br_3 deriv. by reduction and oxidation of the hydroquinone. 1,4,6,2-$Br_4C_{10}H_4OH$ (Franzen and Stauble, *C. A.* **16**, 1945, termed this the 1,3,6-compd.) and HNO_3 in $CHCl_3$ give 60% of *1,4,6-tribromo-1-nitro-2-ketonaphthalene 1,2-dihydride*, yellow, m. 145°; with NaOH in EtOH there results the red Na salt of 4,6,1,2-$Br_2(O_2N)C_{10}H_4OH$; boiling in 5 parts

C_6H_6 gives *4,6-dibromo-1,2-naphthoquinone* (V), orange-red, m. 153°, also obtained from the naphthol and HNO_3 in boiling AcOH; it is unstable and on drying on the water bath, in the light and on continued boiling of a C_6H_6 soln. gives a compd. m. about 100° higher. $PhNH_2$ in EtOH gives quant. *6-bromo-2-hydroxy-1,4-naphthoquinone anil*, red, m. 276°; excess $PhNH_2$ gives the *2-anilido deriv.*, m. 211°. V and concd. HCl in EtOH give *6-bromo-2-hydroxy-1,4-naphthoquinone*, yellow, m. 203°; the alkali salts are deep red; the same compd. is formed from III by the same reaction. Heating V in AcOH 1 hr. gives *3,6-dibromo-2-hydroxy-1,4-naphthoquinone* (VI), the halogen migrating from the 4- to the 3-position. 1,3,4,6,2-$Br_4C_{10}H_3OH$ with HNO_3 in AcOH gives, on heating 20 sec. to boiling after soln. results, 3,4,6-tribromo-1,2-naphthoquinone (VII), red, m. 191°; the *quinoxaline*, yellow, m. 250°; careful reduction with $SnCl_2$-AcOH gives *3,4,6-tribromo-1,2-dihydroxynaphthalene*, m. 160°; longer action of the reducing agent gives 3,6,1,2-$Br_2C_{10}H_4(OH)_2$; oxidation gives the quinone and a compd., probably *3,6,3',6'-tetrabromo-1,2,1',2'-tetrahydroxy-4,4'-dinaphthyl*, m. 293°. Heating VII in AcOH 2 hrs. or better with concd. H_2SO_4 gives VI, golden yellow, m. 219°; the alkali salts are red. VII and 2 mols. $PhNH_2$ in EtOH give *3,6-dibromo-2-hydroxy-1,4-naphthoquinone anil*, dark red, m. 185°; excess $PhNH_2$ gives the *6-bromo-2-anilino deriv.*, brownish red, m. 211° (decompn.); the HCl soln. is violet; the same compd is obtained from 6-bromo-1,4-naphthoquinone and *6-bromo-2-hydroxy-1,4-naphthoquinone anil*, m. 276°. VII and fuming HNO_3 give *3,3,6-tribromo-1,2,4-triketonaphthalene 1,2,3,4-tetrahydride*, m. 157°, crystg. with 1 mol. H_2O; reduction gives 3,6,1,2,4-$Br_2C_{10}H_3(OH)_3$. *1,3,5,6-Tetrabromo-2-naphthol* (VIII), m. 186°, results in a small yield in the prepn. of the 1,3,4,6-Br_4 deriv. (F. and S.); in 75 g. yield from 100 g. β-$C_{10}H_7OH$ and 1-vol. of Br on the water bath; in 40% yield by reduction with Zn and AcOH of *1,1,3,3,5,6-hexabromo-2-keto-4-acetoxynaphthalene 1,2,3,4-tetrahydride*, yellow, m 174.5° (decompn.), obtained by bromination of 1,5,6,2,2-$Br_3(HO)C_{10}H_3CO_2H$ in AcOH and AcONa. VIII with HNO_3 in AcOH gives *1,3,5,6-tetrabromo-1-nitro-2-ketonaphthalene 1,2-dihydride*, pale yellow, changing at 85° or on heating the C_6H_6 soln. to *3,5,6-tribromo-1,2-naphthoquinone* (IX), fiery red, m. 184° (70–80% yield); the *quinoxaline*, yellow, m. 271°; with 3 mols. $PhNH_2$ in EtOH there results *5,6-dibromo-2-anilino-1,4-naphthoquinone anil*, violet or bronze needles, decompg. 221°. Heating IX in AcOH or EtOH-HCl gives *3,5,6-tribromo-2-hydroxy-1,4-naphthoquinone*, yellow, m. 232°. In the prepn. of IX from VIII and HNO_3 in AcOH there results a *compd.*, $C_{10}H_6O_5NBr_4$, m. 121° (decompn.), cystals with 1 mol. AcOH, m. 115° (decompn.); heating in C_6H_6, benzine or EtOH gives IX; reduction with $SnCl_2$-AcOH gives 90% of *3,5,6-tribromo-1,2-dihydroxynaphthalene*, m. 181°; di-Ac deriv., m. 171° (?, original gives 17.1°). β-$C_{10}H_7OH$ (144 g.) and 400 g. AcONa in 1 l. AcOH, treated drop-wise with 50 cc. Br and then with 1 portion of 60 cc. Br, give 65–75% of 1,1-dibromo-2-ketonaphthalene, 1-2 dihydride (X); Br in AcOH gives the 1,1,3,6-Br_4 deriv.; Br in $CHCl_3$ at —15° gives *1,1,3,4,6,7-hexabromo-2-ketonaphthalene 1,2,3,4,6,7-hexahydride* (XI), m, 173°, stable toward cold NaOH or H_2SO_4 but decompd. on warming; $SnCl_2$ or Hi gives 1,3,2-$Br_2C_{10}H_5OH$. XI and Ac_2O with a little concd. H_2SO_4 gives *1,1,3,4,6,7,-hexabromo-2-acetoxy 1,4,6,7-tetrahydride*, m. 178° (decompn.); reduction with Zn and AcOH gives 1,3,2-$Br_2C_{10}H_5OAc$, m. 102°; C_5H_5N splits off HBr, giving the *Ac deriv.*, m. 221°, of *1,3,6,7-tetrabromo-2-naphthol*, m. 174°; oxidation with HNO_3 gives 4,5-dibromophthalic acid. 2-$HOC_{10}H_6Me$, brominated in AcOH and AcONa and the ketobromide reduced with Zn in AcOH gives *3-bromo-2-hydroxymethylnaphthalene*, m. 76°; *Ac. deriv.*, m. 77°. Further bromination gives the *3,6 di-Br deriv.*, m. 110°; *Ac deriv.* m. 136°; and then the *3,4,6-tri-Br deriv.*, m. 158°; *Ac deriv.*, m. 202°. The 3,6- or 4,6-Br_2 deriv. gives *1,4,6-tribromo-1-methyl-2-ketonaphthalene 1,2-dihydride*, yellow, m. 124° (decompn.); with 15 parts $PhNH_2$, warmed 10 min and then treated with 20 parts AcOH, there results the *6-bromo-1,4-dianilino deriv.*, yellow, m. 250° (decompn) 1,2-$BrC_{10}H_6OH$ in HBr or HCl with KI or $SnCl_2$ gives β-$C_{10}H_7OH$; free III alone does not produce the same result. Similarly, 1,6,2-$Br_2C_{10}H_5OH$ was transformed into 6,2-$BrC_{10}H_6OH$ and then into β-$C_{10}H_7OH$; 1,2-$ClC_{10}H_6OH$ into β-$C_{10}H_7OH$ and 1,4,2-$Cl_2C_{10}H_5OH$ into 4,2-$ClC_{10}H_6OH$; the reaction seems to be general for halogen derivs. of β-$C_{10}H_7OH$, substituted in the 1-position; it does not apply to halogen derivs. of phenol. 1,1-Dichloro-2-ketonaphthalene 1,2-dihydride (Zincke, *Ber.* 21, 3540) is yellow and m. 54°; the green H_2SO_4 soln. evolves HCl; HCl-AcOH gives 1,4,2-$Cl_2C_{10}H_5OH$; HBr-AcOH gives 1,6,2-$ClBrC_{10}H_5OH$. *1-Chloro-1-bromo-2-ketonaphthalene 1,2-dihydride*, pale yellow, m. 90°, is formed from 1,2-$ClC_{10}H_6OH$ or 1,2-$BrC_{10}H_6OH$; reduction gives 1,2-$ClC_{10}H_6OH$; HCl-AcOH or HBr-AcOH gives 1,6,2-$ClBrC_{10}H_5OH$, m. 105°. 2,3-$HOC_{10}H_6CO_2H$ and Cl in AcOH give 1,1,3,3,4-pentachloro-2-ketonaphthalene 1,2,3,4-tetrahydride, m. 116°; reduction with Zn dust in AcOH gives 1,3,2-$Cl_2C_{10}H_5OH$, a simple method of prepn. 1,1,6-Tribromo-2-ketonaphthalene 1,2-dihydride and HBr-



AcOH give 1,6,2-$Br_2C_{10}H_6OH$, m. 106°. **X** and C_5H_5N, at a temp. not over 40°, give the *compd.* $C_{15}H_{11}ONBr_2$ (**XII**), yellow, m. 320° (decompn.); with aq. AcONa there is formed the *compd.* $C_{15}H_{10}ONBr$ (**XIII**), golden yellow with 2 mols. H_2O, or deep red when anhyd., m. 250° (decompn); HBr gives **XII**; Ac_2O-H_2SO_4 gives the *compd.* $C_{15}H_{20}O_4NBrS$ (**XIV**), darkens 325°, m. 330°, hygroscopic, very stable toward NH_3 and dil. alkali at room temp.; heating with AcOH or aq. AcONa gives **XIII**. Dehydro-1-methyl-2-naphthol, m. 144°, is formed from 1-methyl-1-bromo-3-ketonaphthalene 1,2-dihydride and 1,2-$MeC_{10}H_6ONa$ in C_6H_6.

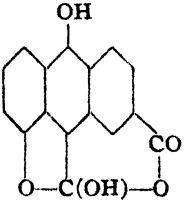
Derivatives of the anthracenes. IV. Indole derivatives of the anthracenes. Paul Ruggli and Ernst Henzi. *Helv. Chim. Acta* **13**, 409–37(1930); cf. *C. A.* **23**, 2711.—Nitration of 2-methylanthraquinone with KNO_3 in H_2SO_4 gave *1-nitro-2-methylanthraquinone* (**I**) which was reduced with Na_2S to give the *amino deriv.* (**II**) **II** (20 g.) was heated for 4 hrs. in 100 cc. $PhNO_2$ with 5 cc. $PhNH_2$ in the presence of 5 g. anhyd. KOAc. Cooling pptd. 17 g. of red-violet *1-amino-2-phenylazomethinanthraquinone* (**III**), m. 212–3°. **III** with concd. H_2SO_4 gave the dark brown *1-aminoanthraquinone-2-aldehyde* (**IV**). **IV** (2.51 g.) in 25 g. $H_2SO_4.H_2O$ with 5 g. Ac_2O dropped into H_2O pptd. 1.9–2 g. yellow-green *1-acetamidoanthraquinone-2-aldehyde* (**V**), sinters 220–30°, m. 237–40° (from xylene and $PhNO_2$). **V** with MeOH-KOH or upon long warming with concd. H_2SO_4 gave **IV**. **IV** (2.51 g.) in 10 cc. hot $PhNO_2$ with 3 g. BzCl gave the carmine-red *anhydro-bis(1-aminoanthraquinone-2-aldehyde)* (**VI**), m. 380–90° (from $PhNO_2$)(decompn.). Heating **III** or **IV** with $ClCH_2CO_2H$ and NaOAc failed to give a *glycine deriv.*, but **IV** so treated gave a dark red *condensation product*, $1,2\text{-}C_6H_4(CO)_2C_6H_2[N{:}CHC_6H_3(CO)_2C_6H_4]CH$ NPh, m. 334° (from C_4H_4N), cherry-red in concd. H_2SO_4, orange on warming and yellow at 100°. The hot soln. thrown into cold water ppts. **IV**. 1-aminoanthraquinone (22.3 g.) was warmed with 21 g. *p*-$MeC_6H_4SO_2Cl$ in 100 cc. C_4H_4N. Cooling pptd. 34 g. *p-tolylsulfon-1-aminoanthraquinone* (**VII**). **VII** (3.8 g.), 0.56 g. KOH and 6 g. $(CH_2Br)_2$ in 25 cc. hot AmOH gave 1.1 g. *bromoethyl-p-tolylsulfon-1-aminoanthraquinone* (**VIII**), m. 165° (from HOAc). **VIII** was dissolved in concd. H_2SO_4 and heated to 50–60°, the red color changing to yellow, the soln. then cooled and thrown into cold water, quantitatively pptg. *1-(β-bromoethylamino)anthraquinone* (**IX**), m. 266° (from HOAc). **IV** (2.51 g.) and 1.2 g. semicarbazide-HCl in 250 cc. hot HOAc and 1.2 g. NaOAc gave 2.7–8 g. of the *semicarbazone* (**XI**), m. 350–60° (from alc.) (decompn.). **IV** (2.51 g.) 1.5 g. *$NH_2OH.HCl$* and 1.8 g. NaOAc in HOAc gave 2.0 g. of oxime, m. 282° (from HOAc) (decompn.). **IV** (2.51 g.), 0.65 g. $N_2H_4.H_2SO_4$ and 1 g. NaOAc in HOAc gave *azine* of *1-aminoanthraquinone-2-aldehyde* (**XII**), m. 375°. **V** (2.9 g.) with 1.2 g. $PhNHNH_2$ in HOAc gave the red *phenylhydrazone*, m. 254° (from HOAc). **V** (2.91 g.) with 2 g. *o,p*-dinitrotoluene in 10 cc. $PhNO_2$ heated to 110–20° with 6 drops piperidine gave 2.9–3 g. of *1-acetamido-2 (o,p-dinitrophenylvinyl)anthraquinone* (**XIII**), $C_6H_4(CO)_2C_6H_2(NHAc)\text{-}CH{:}CHC_6H_3(NO_2)_2$, m. 268° (from $PhNO_2$). The Ac group is split from **XIII** by hot concd. H_2SO_4, MeOH-KOH or aq. alkali. **XIII** (2 g.) in 20 g. cold concd. H_2SO_4 heated to 80–90° and thrown into 200 cc. ice water gave the homologous free amine, m. 286–90° (from $PhNO_2$) (decompn.). **V** (2.9 g.), heated for 3 hrs. with 1.8 g. $PhCH_2CO_2Na$ in Ac_2O, gave 2.2 g. of *3-phenyl-7,8-phthaloylcarbostyril* (**XIV**), $C_6H_4(CO)_2C_6H_2.NH.CO.CPh{:}CH$, m. 278° (from C_5H_5N). **XIV** with MeOH-KOH in C_5H_5N gave a purple *K salt*, easily hydrolyzed by H_2O. **II** (11.8 g.) and 3.3 g. $(COCl)_2$ in PhH gave 12.1 g. of the *bisoxalyl deriv.* (**XV**), m. 330–5° (from $PhNO_2$) (decompn.). An unsuccessful attempt was made to prep. a *diindyl deriv.* by reacting **XV** with AmONa. 2-aminoanthraquinone (**XVI**) (2.23 g.) and 1.6 g. $CH_2(CO_2Et)_2$ in hot $PhNO_2$ gave 2.4 g. *malonylbis(2-aminoanthraquinone)* (**XVII**), m. 310°. **XVI** (50 g.) was reduced by heating 8 hrs. with 80 g. Zn dust in 2 l. 5% NaOH, yielding 35 g. *β-anthramine* (**XVIII**), m. 238° (from PhMe). **XVIII** (19.3 g.) with 15 g. $CHBr(CO_2Et)_2$ in alc. gave 14–15 g. *di-Et β-anthraminomalonate*, m. 131° (from alc.) (closes alc. at 200°), 15 g. of which was heated to melting at 131°, giving a distillate of 2.4–6 g.

alc. and leaving a residue of 12 g. *Et anthracene-1,2-indoxylate* (**XIX**), $R.CO.CH(CO_2Et).NH$ ($R{=}C_6H_4{<}^{CH}_{CH}{>}C_6H_2$), m. 203° (from acetone), sol. in hot alkali. The former reaction also gave 0.8 g. of *dianthracene-1,2-indoxylic anhydride*, $\begin{matrix} CO.CH.CO.N{-}R \\ | \quad | \quad\quad | \quad | \\ R{-}N{-}CO{-}CH.CO \end{matrix}$, almost insol. in all org. solvents, but difficultly sol. in cold concd. H_2SO_4. One g. **XIX** in 20 cc. hot AmOH with KOH gave an enolic *K salt* (**XX**), m. > 360°, which gave **XIX** with acids. **XIX** (3 g.) heated with 20 cc. Ac_2O gave 2.9–3.0 g. of the *N-Ac deriv.* (**XXI**), m. 265–70° (from HOAc) (decompn.), which with alc. KOH gave **XX**. **XXI** when sapond. with 5% KOH in MeOH gave *anthracene-isatin* (**XXII**), m. 286° (from HOAc). **XIX** (3.5 g.) with 14 g. NaOH in 5 cc. H_2O at 170–80° gave 0.9 g. *indigo dye*, m. 425–30° (from $PhNO_2$) (decompn.), insol. in all low-boiling org. solvents. Heating a suspension in H_2SO_4 to 145–50° gave a color change from green to red. Cooled and thrown into H_2O the *sulfonate* pptd. One g. **XXI** in 20 cc. cold H_2SO_4 was heated to 100° by the addn. of H_2O, then thrown into ice and made alk. with dil. NaOH. The resulting soln. was oxidized with a stream of air giving a violet ppt., insol. in acid, alkali and salt solns., but giving a colloidal soln. in H_2O. The oxidation of an alk. soln. of **XIX** with air gave **XXII** which with $PhNHNH_2$ gave a red *phenylhydrazone*, m. 275–7° (from $PhNO_2$) (decompn.), and with *o*-$C_6H_4(NH_2)_2$ an *indophenazine* (**XXIII**), m. 395–400° (from $PhNO_2$).

(**XXII**)

(**XXIII**)



To 3.47 g. **XXI** in 40 cc. boiling HOAc was added 3 g. Cr_2O_3 giving 1.3 g. of the *anthraquinone deriv.*, m. 275–90° (from HOAc) (decompn.) T. H. RIDER

New compound of benzaldehyde and anthrahydroquinone. HAROLD A. BEATTY. *J. Am. Chem. Soc.* **53**, 378–80(1931).—Com. BzH (250 cc.), 10 g. anthraquinone (I), 10 g. BzOH, 1 cc. HCl and 20 cc. EtOH, in a sealed tube, exposed to light until the I has dissolved, the soln. steam-distd., the tar freed from resinous matter by EtOH and Et_2O and the residue dissolved in hot EtOH and treated with 2 vols. $Na_2S_2O_4$, give 10% of a *compd.*, $C_{28}H_{20}O_3$, m. 211–2° (cor., decompn. and sublimation of I), slowly hydrolyzed by EtOH-alkali and more rapidly by EtOH-HCl to BzH and anthrahydroquinone; 0.6 g. dissolve in 100 cc. boiling 95% EtOH; concd. H_2SO_4 gives a red soln., turning brown. It may result by the condensation of 2 mols. BzH with 1 of oxanthrone. C. J. WEST

Preparation of 1-amino-5-chloroanthraquinone and of 1-amino-5-tolylaminoanthraquinone. T. MAKI AND Y. NAGAI. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 464–6(1930)(in German).—1-$C_6H_4(CO)_2C_6H_3SO_3K$ (40.0 g.) in 160 cc. concd. H_2SO_4 was nitrated with 9.0 cc. HNO_3 (d. 1.40) at 50°, followed by heating for 1 hr. at 95°. *5-Nitroanthraquinone-1-sulfonic acid* (I) sepd. on cooling (yield 60%), whereas the 8-isomer remained dissolved (yield, on dilg. with ice, 30%). To 22.8 g. of I (K salt) in 600 cc. boiling H_2O and 85 cc. concd. HCl, 20.0 g. $KClO_3$ in 100 cc. H_2O was slowly added, boiling being continued for 1 hr. A yield of 16.0 g. of *1-chloro-5-nitroanthraquinone* (II), m. 314.8°, was obtained. A paste of 15.0 g. of II, 30 g. cryst. Na_2S, and a little H_2O was mixed with 500 cc. H_2O and heated until reduction to the scarlet-red *1-amino-5-chloroanthraquinone* (III), m. 218.9°, was complete; yield 13.0 g. A colloidal suspension of the product dyed acetylcellulose a bright orange-yellow, with good affinity. Refluxing 10.0 g. of III and 150 g dry *p*-toluidine with 5.0 g. dry AcONa for 2 hrs. at 200°, gave *1-amino-5-tolylaminoanthraquinone*. The reaction mixt. was dild. with alc., 11.0 g. of violet-black crystals, m. 160.2°, was isolated. The product dyed acetylcellulose a violet-red. It was sulfonated on heating with concd. H_2SO_4 at 95°, yielding a magenta-red acid dye of good fastness. K. H. ENGEL

Blue carboxylated anthrahydroquinone-α-carboxylic acid lactones (II) and the formation therefrom of bicyclic condensed lactol-*ps*-carboxylic acids. ROLAND SCHOLL AND OSKAR BÖTTGER. *Ber.* **63B**, 2432–40(1930); cf. *C. A.* **25**, 695–6.—It had been observed that 1,2-$C_6H_4(CO)_2C_6H_2(CO_2H)_2$ (I), its anhydride (II) and imide are converted by Cu powder and concd. H_2SO_4 into blue substances which were assumed to be "oxanthronyls," although they differ from the relatively stable aroyloxanthronyls in their great sensitivity toward air and Ac_2O. Meanwhile it was shown, in Paper I, that the red anthrahydroquinone-1,4-dicarboxylic acids on short heating with aq. HCl or

AcOH yield monolactones sensitive to air and AcOH and which are *blue* both in solid form and in org. solvents. This suggested that the blue compds. obtained from I and its derivs. might also be lactone carboxylic acids and not oxanthronyls. This has been confirmed experimentally, but because of the proximity of the CO_2H groups to each other the picture is not so simple as with the 1,4-di-CO_2H derivs. On boiling I for a short time with $Na_2S_2O_4$ and AcOH or the orange hydroquinone acid (III), obtained by pptg. the cold $Na_2S_2O_4$ vat with HCl, in the aq. HCl suspension, there is obtained a product (IV), at once cryst. in the 1st case, at first amorphous in the 2nd case, which seps. from AcOH, AcOEt or dioxane in beautiful dark blue crystals forming in indifferent org. solvents blue-violet to blue solns. sensitive to the air. They have the compn. $C_{16}H_8O_5$, like the monolactone of the 1,4-acid, and the radical formulas $C_{16}H_7O_5$ or $C_{16}H_9O_5$ are excluded by the fact that IV consumes 2 equivs. O when titrated with $KMnO_4$ in Me_2CO-AcOH or NaOCl-NaOH. Its properties, however, indicate that it is not a monolactone of III. It is so closely related, genetically, to II that it is rather a lactol, or *ps-anthrahydroquinone-1,2-dicarboxylic acid lactone*,

These genetic relationships are as follows: (1) IV is also formed from II and $Na_2S_2O_4$ on short boiling in AcOH or gentle warming with Na_2CO_3, under which conditions the anhydride ring of II is not opened. (2) In cold AcOH suspension $FeCl_3$ quickly converts it into II, and in the blue solns. in indifferent org. solvents, even air oxidizes it to II; with $KMnO_4$ in Me_2CO-AcOH it therefore consumes 2, not 1, equivs. of O. In its formation from I or III, the lactone ring is undoubtedly formed first and then the anhydride ring, whereas in its formation from II the lactone ring is formed last. The phys. and chem. properties of IV agree with this structure. Its absorption in AcOEt in the ultra-violet corresponds to that of the monolactone of the 1,4-acid and the lactone of the 1-acid (max. at 2435 and 3200 and min. at 2245, 2700 and 3640). As expected, the lactol ring is opened with extraordinary ease. The soln. in anhyd. C_5H_5N remains blue only a short time and in greatly dild. aq. C_5H_5N or ordinary alc. (contg. H_2O) it dissolves on heating almost at once with red color. I and II with $Na_2S_2O_3$ and cold NaOH (only 1–2% in the case of II, to prevent opening of the anhydride ring) form different red vats (*A* and *B*). *A* is decolorized by air through olive intermediate stages, the freshly prepd. *B* through pure red, relatively air-stable intermediate stages. With $Na_2S_2O_3$ and NH_3, I gives a normal vat (C) practically identical with *A*, and II at room temp. a brown-red vat (*D*) with which HCl forms a ppt. which is blue-violet or almost instantly changes from brown to blue-violet. IV with cold dil. NaOH forms a red soln. identical with vat *B*, with hot dil. NaOH vat *A*, with cold Na_2CO_3 a blue, relatively air-stable soln., with boiling Na_2CO_3 discolored solns. turning blue when shaken with air and again discolored on standing and finally colorless when the process is repeated many times; the discolored solns. probably contain mixts. of the blue salt of IV and the red salt of vat *B*. Aq. NH_3 at room temp. gives a soln. similar to that in hot Na_2CO_3; after decolorization it probably contains $1,2\text{-}C_6H_4(CO)_2C_6H_2(CONH_2)CO_2H$, for it gives vat *D* with $Na_2S_2O_4$ and NH_3. I boiled a few min. with $Na_2S_2O_4$ in AcOH-Ac_2O gives, through the blue IV, a *mono-Ac deriv.* of IV, m. 255–6°, brown-red with violet tinge, sol. in org. solvents with violet-red color and easily sol. in cold dil. NaOH and NH_4OH, converted into III by hot NaOH. Short boiling of IV with Ac_2O-NaOAc gives an orange *di-Ac deriv.*, m. 284–5°, can be crystd. from boiling AcOH without decompn., is only slowly sol. in cold dil. NaOH and NH_4OH and converted into III on heating. IV is dark blue to almost black in incident, violet (in thin layers) in transmitted light, m. above 290° (decompn.). C. A. R.

Behavior of anthraquinonecarboxylic acids toward sodium hyposulfite, and anthranol-α-carboxylic acid lactones. ROLAND SCHOLL AND OSKAR BÖTTGER (WITH JOHANNES HORN). *Ber.* **63B**, 2440–6(1930).—It has been shown in earlier papers that anthrahydroquinone-1-carboxylic and -1,2-, -1,4- and -1,5-dicarboxylic acids, as obtained by pptn. from their alk. $Na_2S_2O_4$ vats prepd. in the cold, are easily lactonized by Ac_2O and in part even by hot HCl. On the other hand, if the vats are heated to a

more or less high temp., treatment of the pptd. vat acids with Ac_2O gives different results. 1,5-$HO_2CC_6H_3(CO)_2C_6H_3CO_2H$ (I) with alk. $Na_2S_2O_4$ at room temp. gives a red air-sensitive vat from which HCl ppts. the violet hydroquinone acid (II), but if the red alk. vat is heated to boiling even for only 1 min., HCl, after cooling, gives a brick-red-brown ppt. (III) of entirely different properties. As it is insol. in indifferent solvents it cannot be purified by crystn. It dissolves in boiling Ac_2O and on cooling there seps. a yellow-brown cryst. compd. $C_{16}H_{10}O_5$ (IV), showing the properties of both a mixed anhydride with AcOH and of a lactone. It is only slowly sol. in cold dil. NaOH, loses AcOH with boiling 50% AcOH to form a yellow-brown lactonic acid $C_{16}H_8O_4$ (V) which is easily sol. in cold NaOH and, on heating a short time with NaOH, takes up water to form an orange-red di-CO_2H acid $C_{16}H_{10}O_6$ (VI), also obtained directly from IV with hot NaOH. VI can be only *anthranol-1,5-dicarboxylic acid*, for in alk. soln. it changes in the air into I. The mechanism of the reaction is now clear. I in the hot alkali is reduced by $Na_2S_2O_4$ past the II stage to VI which by Ac_2O is at the same time lactonized and converted into the mixed *anhydride* (IV) of AcOH and *anthranol-1,5-dicarboxylic acid lactone* (V). The reaction also takes place with 1-$C_6H_4(CO)_2C_6H_2CO_2H$ and the 1,2- and 1,4-di-CO_2H acids but not with the same ease. The 1-CO_2H and 1,2-di-CO_2H acids require long heating with the alk. $Na_2S_2O_4$ The product from the 1-acid was so unhomogeneous that it was not further investigated. The 1,4-acid after 5 min. boiling gave the *anthranol-1,4-dicarboxylic acid* (VII) in bright flesh-colored needles and readily yielded the red *lactonecarboxylic acid* (VIII). The 1,2-acid is reduced to the anthranol stage only after long boiling. The resulting yellow acid is without doubt a mixt. of 9- and *10-anthranol-1,2-dicarboxylic acids* (IX and X), for with Ac_2O it gives a dark red compd. $C_{16}H_8O_4$ (XI) and a yellow acetate $C_{18}H_{10}O_5$ (XII); XI cannot be converted into XII by further treatment with Ac_2O. The 2 compds. can be sepd. from each other only with difficulty and with considerable loss and they were therefore not thoroughly studied. XI is believed to be the *ps-form* of the lactone of VI (see preceding abstr.); it is only slowly sol. in NH_4OH, forms in NaOH a relatively air-stable red soln. and HCl gives a yellow ppt., presumably the free IX which with boiling AcOH or $C_6H_3Cl_3$ regenerates XI. XII is supposed to be the *acetate* of *10-anthranol-1,2-dicarboxylic anhydride;* it dissolves in hot NaOH with much more yellowish red color than XI, forming a relatively air-stable soln. and giving with HCl a yellow ppt., probably of the free X. IV (60% yield), decomps. above 285°. V, darkens above 310° and decomps. without melting. VI, m. above 310°. VIII (yield, 75%), does not m. 325°. VII, becomes dark red at 250° XI, m. 278°. XII, m. 266–7°, sol. in AcOEt with yellow color and green fluorescence in AcOH and Ac_2O without fluorescence, in concd. H_2SO_4 with yellow color. C. A. R.

Action of nitrous acid on primary tetrahydro-α-furfurylamine. N. V. Williams *Compt. rend. acad. sci. U. S. S. R.* **1930A**, No. 16, 424–8.—The reaction has been found to be quite complicated, resulting in the formation of products of various nature, and seems to be similar to the decompn. of nitrous salts of amines of the polymethylene series contg. a side chain CH_2NH_2. The predominance of primary alc. in the products of reaction is concluded to be related to the stability of the pentacycle. Substitution of O for CH_2 does not remove the ability of the heterocycle to isomerize. It is pointed out that a further detailed study of the reaction is necessary. Robert Schless

Furan derivatives. I. J. Rinkes. *Rec. trav. chim.* **49**, 1118–25(1930).—2-Methylfuran was prepd. according to the method of Wolff-Kischner (*Ann.* **394**, 86(1912), cf. Reichstein, *C. A.* **24**, 3781) and nitrated according to Marquis (*Ann. chim. phys.* [8], **4**, 196(1905)) with Ac_2O-HNO_3 at —5°. The reaction product is poured out on ice dild. with water and the intermediate product, $O_2NC(OAc):CHCH:C(OH)Me$, is extd. with ether. After evapn. of the ether, the furan ring is closed again by the addn of an equal vol. of pyridine, which is added gradually. On distg. the reaction product with steam, first oil drops are obtained which solidify on cooling and which may be recrystd. from petroleum ether; solidification point 43.5°; b_{12} 104°. This compd. has a smell like *p*-nitrotoluene and is the furan analog of this substance, the *2-methyl-5-nitrofuran*. During the last part of the distn. with steam an oily compd. is obtained, which only solidifies after about a day and which, by recrystn. from EtOH, is obtained in the form of octahedric crystals, m. 77–8°. This compd. is the *1-methyl-2,4-dinitro-1,3-butadiene-1,4-diol monoacetate*, $O_2NC(OAc):CHC(NO_2):C(OH)Me$, which, with pyridine, does not undergo a ring closure, probably because of a hindering influence of the 2nd nitro group. *2-Methyl-5-formylfuran* was prepd. according to Middendorp (*C. A.* **13**, 2344; cf. Fenton, *J. Chem. Soc.* **79**, 807(1901)) and was oxidized to *2-methylfuran-5-carboxylic acid*, m. 108–9°, by means of Ag_2O; the *Me ester*, b_{15} 98°, was obtained by esterification of the acid at room temp. during 2–3 days with MeOH satd. with HCl. On nitration with Ac_2O and HNO_3, *Me 2-methyl-3-nitrofuran-5-*

carboxylate, m. 81°, is obtained at once without treatment of the reaction product with pyridine; it may be isolated by distn. with steam. The nitration of the CO_2H acid itself chiefly leads to the formation of the same nitro deriv. which is formed by the nitration of 2-methylfuran. Thus the nitro group replaces the CO_2H group, a process which takes place with remarkable ease; it takes place much more easily in the furan ring than in the benzene ring, the nitration of *p*-toluic acid only giving 2-nitro-*p*-toluic acid. The same replacement of the CO_2H group takes place in the nitration of nitropyromucic acid to dinitrofuran (Marquis, *loc. cit.* 254). The formation of 2-methyl-5-nitrofuran in the nitration of 2-methylfuran-5-carboxylic acid also proves the position of the nitro group in the nitration product of 2-methylfuran. The 2nd product formed in the nitration of the 5-CO_2H acid, which is not volatile with steam, was obtained in needles, m. 159–60°, and consists of *2-methyl-3-nitrofuran-5-carboxylic acid*. 3-Methylfuran-2-carboxylic acid was prepd. from Elsholtzia ketone according to Asahina (*C. A.* **19**, 1139); on nitration this compd affords *2-nitro-3-methylfuran*, m. 32.6° and volatile with steam, the CO_2H group being again replaced by the nitro group, together with a non-volatile compd. m. 195°, which still contains the CO_2H group, but has not yet been investigated further. Most probably this compd. consists of a nitromethylfurancarboxylic acid. II. *Ibid* 1169–71.—According to Marquis (*Ann. chim. phys.* [8], **4**, 227(1905)) the nitration of furan gives 3-nitrofuran and a dinitro compd., m. 101.5°, with one of the NO_2 groups in the 3-position. This dinitrofuran was, however, identical with the 2,5-dinitrofuran prepd. by Hill and White (*Am. Chem. J.* **27**, 193(1902)) by nitration of 5-nitropyromucic acid, the latter being obtained by nitration of 5-sulfopyromucic acid or dehydromucic acid (Klinkhardt, *J. prakt. Chem.* **25**, 51(1882)). It thus follows that the mononitro compd. obtained by M. is the 2-nitrofuran. All substitutions in the furan ring take place at the *o*-position with respect to the indifferent O atom; if this position is occupied by a group which is readily displaced, a displacement takes place while in the case of a group which cannot be displaced (*e. g.*, the Me group), the substitution takes place at the 5-C atom. According to Reichstein (*C. A.* **24**, 3781) the aldehyde group is also introduced into furan in the 2-position with the formation of furfural while the same reaction with 2-methylfuran gives 2-methyl-5-formylfuran. It is now shown that the nitration of pyromucic acid with Ac_2O and HNO_3 (d. 1.51) at −10° gives a mixt. of about equal amounts of 2-nitrofuran, m. 27.9°, which was identical with the direct nitration product of furan itself, and of 5-nitropyromucic acid, m. 183°. The yield was, however, small, only 2.5 and 3.8 g. of these compds. being obtained from 50 g. pyromucic acid. The products of the reaction could be sepd. by distn. with steam, the 2-nitrofuran being volatile and the nitropyromucic acid remaining behind.

C. F. VAN DUIN

Synthesis of some new compounds in the pyrrole and pyrrolidine series. LYMAN C. CRAIG AND R. M. HIXON. *J. Am. Chem. Soc.* **53**, 187–90(1931); cf. *C. A.* **24**, 1374.—*N*-Butylpyrrole (I) was prepd according to Reichstein (*C. A.* **21**, 2451), except that mucic acid was used; 60 g. $BuNH_2$ give 13.5 g. I, b. 165–80°, and *N*-butylpyrrole-α-butylcarboxamide, m. 57° (R. terms this the α-isobutylamide); hydrolysis of 10 g. with 8 g. KOH in 4 cc. 95% EtOH by heating 10 hrs. at 200° gives the free *acid*, whose *amide* m. 108°. *N*-Substituted pyrroles can be catalytically reduced easily to the corresponding pyrrolidine compds. in EtOH-HCl soln. This method of prepn. is to be preferred over that of condensation of RX with pyrrolidine as the yields are often low by the latter method due to formation of the quaternary derivs. Reduction of I gives 88% of *N*-butylpyrrolidine; the picrate m. 124°; *chloroaurate*, yellow, m. 78°. Cl-$(CH_2)_4$Cl (5 g.) and 12.6 g *p*-toluidine give 4.5 g. *N-p-tolylpyrrolidine*, b_8 120°, m. 42.5°; *chloroplatinate*, decomps. 175°. *N*-Benzylpyrrolidine results in only 40% yield from $PhCH_2Cl$ and pyrrolidine (Schlinck, *Ber.* **32**, 952(1899), reports a quant. yield).

C. J. WEST

The catalytic dehydrogenation of pyrrolidine. J. P. WIBAUT, MISS C. C. MOLSTER, H. KAUFFMANN AND MISS A. M. LENSSEN. *Rec. trav. chim.* **49**, 1127–30(1930).—Wibaut and Overhoff (*C. A.* **23**, 148) have shown that nicotine may be dehydrogenated to 3,2′-nicotyrine by means of Pt-asbestos at 320°. Also with simpler pyrrolidine compds. this reaction takes place; Zelinskii and Yur'ev (*C. A.* **24**, 1110) have shown that *N*-methylpyrrolidine is dehydrogenated to *N*-methylpyrrole by means of Pd-asbestos at 250°. According to Z. and I. pyrrolidine behaves differently, but it is now shown that pyrrolidine may be dehydrogenated just as well by means of a suitable catalyst. The reaction product obtained by slow dehydrogenation of pyrrolidine with Pt-asbestos at 360° was fractionated and the presence of pyrrole in the higher-boiling fraction could be demonstrated by the formation of an azo dyestuff with PhN_2Cl according to Fischer and Hepp (*Ber.* **19**, 2251(1886)) which is characterized by a color change

in alk. soln. With Pd-asbestos at 335–60° a reaction product was obtained which showed the presence of pyrrole by the formation of a blue dyestuff with isatin according to Meyer (*Ber.* **16**, 2974(1883); **17**, 1034(1884); cf. Ciamician and Silber, *Ber.* **17**, 142(1884)). The presence of unchanged pyrrolidine in the reaction product could be shown by the formation of pyrrolidine picrate, m. 112°. It thus follows that the catalytic hydrogenation of pyrrole is a reversible reaction. C. F. VAN DUIN

The use of *sym*-dichloroacetone for the preparation of thiazoles. III. C. M. SUTER AND T. B. JOHNSON. *Rec. trav. chim.* **49**, 1066–8(1930).—$CO(CH_2Cl)_2$ was found to react easily with thioamides; the reaction can be formulated easily by taking the dichloroacetone in the enolic and the thioamides in the imide form; particulars of the reaction are not given, only the solvent used being mentioned. The following compds. are described: *4-chloromethyl-2-phenylthiazole* (I), m. 51°; *4-chloromethyl-2-p-methoxyphenylthiazole* (II), m. 55–6°; *4-chloromethyl-2-piperonylthiazole* (III), m. 106–7°; *2-phenylthiazole-4-acetonitrile* (IV), b_4 180–5°; *2-phenylthiazole-4-acetic acid* (V), m. 90°; *HCl salt*, m. 206–7°; *4-phthalimidomethyl-2-phenylthiazole* (VI), m. 151–2°; *2-phenylthiazole-4-methylamine* (VII); mono-HCl salt, 188–9°; di-HCl salt, m. 217–8°; *2-p-methoxyphenylthiazole-4-acetonitrile* (VIII), m. 75°; *4-phthalimidomethyl-2-p-methoxyphenylthiazole* (IX), m. 186–7°; *2-p-methoxyphenylthiazole-4-methylamine* (X); di-HCl salt, m. 224–5°; *di(2-phenylthiazole-4-methyl)amine* (XI); di-HCl salt, m. 190°; *2-p-hydroxyphenylthiazole-4-methylamine* (XII), m. 205–6°. The compds. VII and XI are formed by the action of NH_3 on I in alc., the primary and the secondary amine being formed simultaneously, the first being the chief product of the reaction. This compd. is, however, obtained easily in a pure state by the action of the halide I with K phthalimide and decompn. of the reaction product with acids. The reactivity of the halogen atom in compds. of the type I is about that of the Cl atom in $PhCH_2Cl$. The compds. VII, XI and XII show a marked physiol. activity, the nature of which, however, is not indicated C. F. VAN DUIN

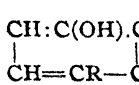
1-Thio-γ-pyrone and derivatives. F. ARNDT AND NADJI BEKIR (WITH W. PARTALE) *Ber.* **63B**, 2393–7(1930).—*1-Thio-γ-pyrone* (I) (0.4–0.7 g. from 2 g. penthianone (II) in 8 cc. cold C_6H_6, treated with 11 g. PCl_5, then after 15 min. refluxed until no more HCl is evolved (30–40 min.), rapidly filtered, at once added to 50 g. ice, treated with excess of pptd. $CaCO_3$, filtered, satd. with NaCl and extd. repeatedly with $CHCl_3$, m. 110°, sol. without color in concd. H_2SO_4. Unlike II, it is easily sol. in H_2O, again pointing to the betaine-like nature of the pyrone system (with no acidic substituents). The *HCl salt*, m. around 135°, is stable; *$HgCl_2$ addn. compd.*, m. 189°; *ferrocyanide*, difficultly sol. light green crystals. II is readily oxidized in AcOH by H_2O_2 to the *sulfone* (2 g. from 5 g. II), m. 171–2°, almost insol. in concd. H_2SO_4; *3,5-dibromo deriv.* (III), obtained with Br in AcOH, m. 220° (decompn.). I, on the other hand, offers great resistance to oxidation; long continued treatment with H_2O_2 results in the splitting off of H_2SO_4. The *sulfone*, light yellow, m. 174°, is obtained, however, by boiling III a short time with C_5H_5N; it is sol. in concd. H_2SO_4 with light yellow color and is immediately decompd. with a violet color by dil. alkali. Although the structure of Apitzsch's di-Et2,6-dithiol-1-thiopyrone-2,5-dicarboxylates, obtained from substituted acetones and CS_2, was established by their compn. and the identification of the side chains, it seemed desirable to show directly the presence in them of the thiopyrone system by means of the characteristic properties of the latter. 2,6-Dimethylmercapto-1-thiopyrone-3,5-dicarboxylic acid, from the di-Et ester through the mono-Et ester (m. 176°) by refluxing in concd. HCl, m. 243–5° (decompn.) (A. gives 230°); heated at 245° until the evolution of gas ceased, it yielded *2,6-dimethylmercapto-1-thiopyrone* (IV), m. 130–1°, which already shows great similarity to the most characteristic of the γ-pyrones, *viz.*, 2,6-dimethylpyrone. It is much less sol. in H_2O, to be sure, but nevertheless it dissolves easily in even 2 *N* acid, *i. e.*, is pronouncedly basic. By oxidation only four O atoms can be introduced; the *product* m. 270°. As the S atoms in the side chains are undoubtedly oxidized to SO_2, it follows that the ring S is not oxidized. *2,6-Dimethylmercaptodithiopyrone*, from IV boiled in C_6H_6 with P_2S_5, yellow-brown, m. 121°, sol. in concd. acids with yellow color. C. MARTIUS from $MeCHClCH_2CO_2H$ readily obtained *Me 2,6-dimethylpenthianone-3-carboxylate*, m. 86°, and converted it with H_2O at 175° into *2,6-dimethylpenthianone*, m. 38.5°, while at 210–20° he obtained a liquid *stereoisomer;* both, on dehydrogenation with Cl or SO_2Cl_2, gave *3-chloro-2,6-dimethyl-1-thiopyrone*, m. 96°, whereas PCl_5 gave only dark blue lakes. C. A. R.

The application of titanium trichloride to the reduction of the carbon-carbon double bond, flavones and flavanones. P. KARRER, Y. YEN AND I. REICHSTEIN. *Helv. Chim. Acta* **13**, 1308–19(1930); cf. *C. A.* **23**, 3227, 4480.—To ascertain the serviceability of $TiCl_3$ in reduction, expts. were carried out on simple unsatd. substances.

$PhCH:CHPh$, $Ph_2C:CH_2$ and $PhC:CPh$ resisted reduction whereas $PhCH:CHCO_2H$, $PhCH:CHCONH_2$ and $PhCH:CHAc$ were transformed to $PhCH_2CH_2CO_2H$, $PhCH_2CH_2CONH_2$ and $PhCH_2CH_2Ac$, resp. $PhCH:CHCH:CHCO_2H$ gave principally $PhCH_2CH:CHCH_2CO_2H$ and a smaller yield of $PhCH:CHCH_2CH_2CO_2H$. $TiCl_3$ would reduce neither $PhCH:CHCO_2Et$ nor $PrCH:CHCO_2H$. It appears that only such ethylenic double linkages which are next to CO groups are reduced by $TiCl_3$ in ammoniacal soln. The behavior of $TiCl_3$ in the reduction of the flavones is in sharp contrast with the above findings. Flavone (I) gave, in addn. to an unknown non-crystallizable compd., a small yield of a pinacol $[C_6H_4.O.CPh:CH.C(OH)]_2$ and 4'-methoxyflavone gave a similar pinacol in smaller yields. The reduction of various flavanones with $TiCl_3$ gave surprisingly good results. Flavanone (II) gave both forms of 4-hydroxyflavan: β-form m. 148–9°, α-form m. 120–0.5°, and traces of a pinacol (cf. *C. A.* **17**, 108), whereas only the α-form is given on reduction with Al-Hg. 6-Chloroflavanone and 4'methoxyflavanone (III) gave the corresponding 4-hydroxyflavans in 1 form only. It was found that the prepns. of I, II and III were best effected by the method of Lowenbein (cf. *C. A.* **19**, 286). The reduction of quercetinol penta-Me ether with $TiCl_3$ gave pentamethylcyanidin (cf. *C. A.* **19**, 1141; **23**, 148). C. R. ADDINALL

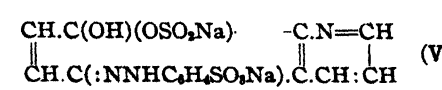
Derivatives of pyridine. A. BINZ AND C. RÄTH. VIII. **Isomerism of derivatives of 2-hydroxypyridine.** C. RÄTH. *Ann.* **484**, 52–64(1930); cf. *C. A.* **24**, 4038.—The *Ag salt*, yellow, of 2-hydroxy-5-nitropyridine (I), with MeI in boiling MeOH for 8 hrs., gives 15.6% of *2-methoxy-5-nitropyridine* (II), m. 108–9°, and 60% of *N-methyl-5-nitro-2-pyridone* (III), m. 175°. 2-Iodo-5-nitropyridine and MeONa in abs. MeOH give 33.8% of II but no III. After heating II with PCl_5 at 140–50° for 4 hrs., 30% II was recovered but the residue was a resinous mass; attempts to rearrange II into III by heating at 150–200°, with or without H_2O, failed. The K salt (IV) of I, crystg. with 2 H_2O, and MeI in 96% EtOH, heated 1.5 hrs., give 0.8% II and 83% III; III was also obtained in 81.8% yield with Me_2SO_4. Heating 7.7 g. III with 12 g. BrCN at 180° in a bomb tube gives the *3-Br deriv.*, m. 124–5°. Reduction of II with $SnCl_2$ and HCl in dry Et_2O gives *2-methoxy-5-aminopyridine*, yellow, m. 135–6°; the colorless di-HCl salt gradually turns brown to black. Reduction of III with Sn and 33% HCl gives a small yield of *N-methyl-5-amino-2-pyridone*, m. 125–6° (decompn.). The Ag salt of I and EtI give 34.3% of *2-ethoxy-5-nitropyridine*, m. 91–2°, and 40% of *N-ethyl-5-nitro-2-pyridone*, m. 142–3°, also obtained in 76.3% yield from IV and EtI in EtOH. The Ag salt of I and $PhCH_2I$ give 21.7% of *2-benzyloxy-5-nitropyridine*, m. 107–8°, while IV and $PhCH_2Cl$ give 87.5% of *N-benzyl-5-nitro-2-pyridone*, dark yellow, m. 105–6°. IV and PrI give 67.8% of the *N-Pr deriv.*, m. 76–7°; iso-PrI gives 52% of the *N-iso-Pr deriv.*, yellow, m. 86–90°; BuI gives 66.8% of the *N-Bu deriv.*, m. 46–7°. The *Ag salt* of 2-hydroxy-5-iodopyridine (V), pale yellow, and MeI in MeOH give 13.9% of *2-methoxy-5-iodopyridine*, pale yellow oil, b_{15} 109–10° (*HCl salt*, m. 145–50° (decompn.)); the base is very unstable; the K salt of V and MeI in KOH give 80% of *N-methyl-5-iodo-2-pyridone*, yellow, m. 73–4° (*HCl salt*, m. 130° (decompn.)); *N-Et deriv.*, m. 75–6° (64% yield) (*HCl salt*); *N-Pr deriv.*, b_{16} 185–8° (74.2% yield) (*HCl salt*, m. 112° (decompn.)); *N-iso-Pr deriv.*, pale yellow, m. 110–1° (60% yield); *N-Bu deriv.*, b_{12} 185° (32.7% yield) (*HCl salt*, m. 125° (decompn.)); *N-octyl deriv.*, b_{14} 221–2° (49.1 yield) (*HCl salt*, m. 85° (decompn.)); *N-benzyl deriv.*, m. 100–1° (42.5% yield). C. J. WEST

Catalytic reduction of α-picoline to pipecoline. P. BORISOV. *Ber.* **63B**, 2278 (1930); cf. Zelinskii and B., *C. A.* **18**, 2167.—α-Picoline, b_{761} 128.5–9.5°, n_{18} 1.5034 (35 g.) was passed at the rate of 10 drops per min. over 29% Pd-asbestos in a 70-cm. quartz tube at 160°. After 2 treatments the n had fallen to 1.4520, and after fractionation, another hydrogenation and a 2nd distn. there was obtained 28 g. pipecoline, b_{747} 117–8°, n_{18} 1.4492, $d_4^{18.5}$ 0.844, mol. refraction 31.47. C. A. R.



Quinoline derivatives. XIII. Degradation of 6-methoxyquinoline-4-carboxylic acid. HANNS JOHN AND EMIL ANDRASCHKO. *J. prakt. Chem.* **128**, 180–9(1930); cf. *C. A.* **24**, 4039.—6-Methoxyquinoline-4-carboxylic acid gives a *Me ester*, m. 84°, and an Et ester, m. 69°. The Et ester and $N_2H_4.H_2O$, heated 40 hrs., give the *hydrazide*, m. 151°; picrate, m. 205°; *isopropylidene deriv.*, $MeOC_9H_6NCONHN:CMe_2$, m. 134°; *methylbenzylidene deriv.*, m. 201°; *p-dimethylaminobenzylidene deriv.*, m. 132°. The azide, yellow, decomps. 106°, gives with EtOH the *6-methoxy-4-quinolylurethan* (I), m. 170°, and on warming in C_6H_6 the *isocyanate*, $MeOC_9H_6NNCO$, m. 171° (decompn.), which is not changed by warming with 30% EtOH-KOH for 10 hrs. on the H_2O bath. The azide, boiled in H_2O until soln. results, gives *N,N'-bis(6-methoxy-4-quinolyl)urea*, m. 205°, soly. in H_2O at room temp., 2.6%; various salts are qualitatively described. I and concd. HCl, gently boiled 4 hrs., give 6-methoxy-4-aminoquinoline, m. 120°. the HCl

salt m. 249°; the picrate m. 192° (decompn.); other salts are qualitatively described; *di-Ac deriv.*, m. 242°. **XIV. Derivatives of quininic acid and xanthoquinic acid.** *Ibid* 190–200.—6-Methoxyquinoline-4-carboxyl chloride-HCl, decompg. 186°, and $ClCH_2CH_2OH$, heated 8 hrs. at 110–2°, give *β-chloroethyl 6-methoxyquinoline-4-carboxylate*, m. 71°; $H_2NCH_2CH_2OH$ gives *6-methoxy-4-quinolylaminoethanol*, m. 143°; $C_6H_4(NH_2)_2$ gives *N,N'-bis(6-methoxy-4-quinolyl)ethylenediamine*, m. 269°. 6-Methoxyquinoline-4-carboxylic acid and HI (d. 2.0), heated 5 hrs. to gentle boiling, give 6-hydroxyquinoline-4-carboxylic acid (I), m. 320° (decompn.); a large no. of metallic salts are qualitatively described; the *acid chloride* m. 158° (decompn.); the *amide* m. 264°; the *diethylamide* m. 119°; the *β-chloroethyl ester* m. 150°. *6-Ethoxyquinoline-4-carboxylic acid*, m. 278°, results from the Et ester of I and EtI with EtOH-KOH; various metallic salts were prepd.; *Me ester*, yellow, m. 58°. **XV. 6-Hydroxy-4-aminoquinoline.** *Ibid* 201–10.—6-Hydroxyquinoline-4-carboxylic acid yields a *Me ester*, m. 212°; an *Et ester*, yellow, m. 185.5°; a *Pr ester*, pale yellow, m. 130°, and an *iso-Pr ester*, pale yellow, m. 157°. The hydrazide m. 244°; *isopropylidene deriv.* does not m. 300°; *methylbenzylidene deriv.* m. 276°. The azide, decomps. 115°, gives with EtOH *6-hydroxy-4-quinolylurethan* (I), m. 236° (decompn.); with C_6H_6 the *isocyanate* (II), light brown, m. 178°; and with H_2O *N,N'-bis(6-hydroxy-4-quinolyl)urea*, pale yellow, m. 253°. I with concd. HCl or II with 30% EtOH-KOH gives *6-hydroxy-4-aminoquinoline*, m. 264°; soly. in H_2O at room temp. 2%; concd. H_2SO_4 gives a pale yellow soln. with a yellow-blue fluorescence; $NaNO_3$ gives a carmine-red soln., HNO_3 a brick-red soln. **XVI. 6-Substituted 4-halogenoquinolines.** *Ibid* 211–7.—Through the diazo reaction 6-hydroxy-4-aminoquinoline gives the *4-Cl deriv.*, m. 210°; the *4-Br deriv.*, pale yellow, m. 253°; and the *4-I deriv.*, pale yellow, m. 283°. Similarly, 6-methoxy-4-aminoquinoline yields the *4-Br deriv.*, m. 106°, and the *4-I deriv.*, m. 85°. The behavior of these compds. with various reagents is qualitatively described. **XVII. 6-Methoxy-4-hydrazinoquinoline, 6-methoxy-4-mercaptoquinoline, 6-methoxyquinoline-4-sulfonic acid.** *Ibid* 218–22.—6-Methoxy-4-chloroquinoline (I) and 100% $N_2H_4.H_2O$, heated 8 hrs. on the H_2O bath, give the *4-hydrazino deriv.*, m. 154°; this gives a *condensation product* with *p*-MeC_6H_4COMe, $MeOC_9H_5NNHN:CMeC_6H_4Me$, m. 105°. I and KSH in abs. EtOH, heated in a sealed tube 15 hrs. at 100°, give the *4-mercapto deriv.*, red, m. 139° I and $NaHSO_3$ in H_2O, heated 20–5 hrs., give *6-methoxyquinoline-4-sulfonic acid*, pale yellow, m. 292° (decompn.); various salts are qualitatively described. **XVIII. Chitenine.** *Ibid* 223–8.—Oxidation of quinine with $KMnO_4$ gives chitenine (I) (Skraup, *Ber.* **12**, 1104(1879)); $SOCl_2$ gives the *chloride*, $C_{19}H_{21}O_2N_2Cl$, m. 206°; MeOH gives the *Me ester*, m. 217°, also obtained from I, MeOH and H_2SO_4; *Et ester*, m. 198°; *hydrazide*, m. 236° (*benzylidene deriv.*, m. 179°; *methylbenzylidene deriv.*, m. 223°). *N,N'-Bischitenylurea*, m. 154°; *picrate*, m. 185°. C. J. WEST



Synthesis of quinoline derivatives. VI. Preparation of certain acylamino derivatives of 8-hydroxyquinoline. KONOMU MATSUMURA AND CHUSABURO SONE. *J. Am Chem. Soc.* 53, 177–9(1931).—The following derivs. of 8-hydroxyquinoline are reported: *5-acetamido* (I), m. 218–9° (*acid sulfate*, yellow, m. 263° (decompn.); the *7-I deriv.* of I, m. 212° (*HCl salt*, yellow, m. 196° (decompn.)); *7-acetamido-5-methyl* (II), pale yellow, m. 203–4° (*sulfate*, yellow, m. 180°); the 8-Ac deriv. of II, m. 222° (*acid sulfate*, yellow, m. 183°); *7-amino-5-methyl*, yellow, m. 141–2° (*picrate*, red, decomps. 215–20°); *5-benzoylamino*, m. 237–8° (*acid sulfate*, yellow, m. 225–7° (decompn.)); *7-benzoylamino-5-methyl-8-benzoyl deriv.*, m. 181°. *5-Acetamido-6-hydroxyquinoline*, m. 278° (decompn.) (*acid sulfate*). *5-Methyl-8-methoxyquinoline*, viscous yellow oil, b_{775} 298–302° *picrate*, yellow, m. 180–1°; *chloroplatinate*, yellow, m. 224° (decompn.). C. J. WEST

Action of sulfurous acid and its salts on quinoline derivatives (preliminary communication). N. N. VOROSHZOV AND I. M. KOGAN. *Ber.* **63B**, 2354–62(1930).—The colorless *o*-hydroxyquinoline (I, R = H) with $NaHSO_3$ gives yellow crystals (II) decompg. in their dark yellow aq. soln. on heating with evolution of SO_2 and regeneration of I. They show the same instability toward weak alkalies or mineral acids and have the compn. $C_9H_7O_2NS$, of a 1:1 *addn. product* of I and SO_2. The color change in the formation of II indicates that the quinoline nucleus plays the chief role in the reaction, and as a matter of fact an analogous *compd.* $C_9H_7O_3NS$ (III) is obtained from quinoline warmed with aq. SO_2 or $NaHSO_3$. Likewise benzeneazo-*o*-hydroxyquinoline (IV) (I, R = PhN:N) yields orange crystals (V) which have not as yet been obtained in analytically pure form, but the color change yellow IV ⟶ orange V and the properties of V indicate that V is analogous to II and III. The yellow *p*-SO_3H deriv. (VI) (I, R = $HO_3SC_6H_4N:N$) of IV, however, reacts quite differently with $NaHSO_3$. Like the corresponding α-naphthol compd., it forms a $NaHSO_3$ instead of a SO_2 *addn. product*, presumably VII, which is dark red; it decomps. into its components in H_2O and in the

presence of $NaHCO_3$, while acids, even in minimal amts., hinder the decompn. **III**, m. 80–1°. **II** m. 127–9°. **IV**, from I in cold NaOH-Na_2CO_3 soln. added to diazotized $PhNH_2$ in HCl, m. 187° (Fox, *C. A.* **4**, 3075, gives 171°). The decompn. of **VII** in H_2O increases with increasing diln. (the % of total SO_2 which is titratable with 0.01 *N* I after 6 hrs. at 25° increases from 1.88 in a 0.02 *N* soln. of **VII** to 14.0 in the same soln. dild. 100-fold) and with increasing concn. of $NaHCO_3$ (from 6.4% in a 0.0016 *N* soln. of **VII** after 6 hrs. at 25° with 0.01 mol. $NaHCO_3$ to 69.7% with 2.50 mols.). With 0.01 to 5.00 mols. HCl in a 0.004 *N* soln. of **VII** kept 6 hrs. at 25°, the decompn. ranged from 3.6 to 2.6%.

C. A. R.

The Doebner reaction. X. L. Musajo. *Gazz. chim. ital.* **60**, 673–7(1930); *C. A.* **24**, 1863.—In the present paper the reaction of furfural (I), β-$C_{10}H_7NH_2$ (II) and $AcCO_2H$ (III) was studied. Alc. I (19.2 g. in 150 cc.), added to hot alc. II (28.6 g. in 550 cc.), brought to boiling, alc. III (17.6 g. in 80 cc.) added, boiled 3 hrs., let stand 48 hrs., and filtered and washed with EtOH, leaves a residue which, purified by soln. in alc. KOH and repptn. with AcOH, gives 53% of α-furyl-β-naphthocinchoninic acid (IV), m. 278° (cf. Doebner, *Ber.* **27**, 2028). With 2 mols. of I and 2 mols. of II per mol. of III, the yield of IV is 80–1%. *Cu salt*, $(C_{18}H_{10}O_3N)_2Cu.1.5H_2O$, prepd. by double decompn. of the Na salt and $Cu(OAc)_2$. The filtrate from the prepn. of IV was then analyzed for secondary products. This alc. filtrate and alc. wash liquors (a total of approx. 900 cc.) concd. to 0.25 of their vol., dild. with water to a little more than the original vol., 10% aq. Na_2CO_3 (200 cc.) added, heated a short time on a water bath, cooled and extd. with Et_2O, yields 2 liquids, an aq. alk. soln. (*A*) and an Et_2O soln. (*B*). Soln. *A*, freed of Et_2O by an air current, acidified with AcOH, filtered and the residue recrystd. repeatedly from EtOH, yields 35–40% of *py-tetrahydro-α-furyl-β-naphthocinchoninic acid* (V), m. 200°. It is the 4th tetrahydrogenated cinchoninic acid synthesized by Ciusa and his collaborators in work on the Doebner reaction. An aq. suspension of V, dissolved by addn. of KOH, cold aq. $KMnO_4$ (1 g.) added slowly, heated gently, filtered, washed, the filtrate acidified with AcOH, the ppt. washed with EtOH and purified by soln. in alc. KOH and repptn. with AcOH, yields **IV**. Though phenylnaphthocinchoninic acid and Hg-Na yield the same tetrahydrogenated acid as is obtained from the reaction of BzH, II and III (cf. Ciusa and Barattini, *C. A.* **20**, 2331), the reaction proceeds otherwise in the reaction of Na-Hg and **IV**. The product is an unidentified *acid*, m. 240°, which will be described more fully in a later paper. Soln. *B*, filtered, evapd., the residual oil dissolved in a little EtOH, filtered, the filtrate extd. repeatedly with benzine, the ext. concd. by warming and the last part of the benzine removed by spontaneous evapn., the residual oil dissolved in Et_2O, dried with Na_2SO_4, evapd., kept *in vacuo* (no tendency to crystallize), and distd. *in vacuo*, yields *α-furylmethyl-β-naphthylamine* (VI), oil, b_{16} 225–30°, does not readily form salts. Alc. VI, acidified with dil. H_2SO_4, aq. $NaNO_2$ added cautiously, filtered, the residue washed with water (until I is no longer liberated from KI), and recrystd. from benzine, yields the *nitroso deriv.*, $C_{18}H_{12}O_2N_2$, of VI, m. 98°, gives the Liebermann reaction. With BzCl, VI forms an unidentified *substance*, m. 168°. With certain diazo compds., alc. VI gives violet dyes which are to be studied further.

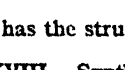
C. C. Davis



Dioximes. LXVII. M. Milone. *Gazz. chim. ital.* **60**, 632–43(1930); cf. Ponzio and Durio, *C. A.* **25**, 80.—Though crystallographic methods do not yet make it possible to correlate mol. structure, chem. properties and cryst. form, the crystallographic consts. of some glyoxime peroxides described in earlier publications, which are known in the form of 2 easily isolated isomers, were detd. in order to compare them with the crystallographic consts. of furazans (which differ from the peroxides only by 1 O atom and yet

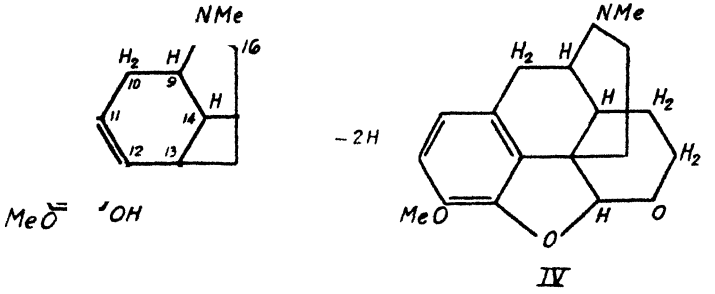
whose constitution is still in doubt). It was impossible to measure the angles of phenylfurazan because of the high vapor pressure and the low m. p. However, its optical properties indicated that it belonged to the triclinic system. The following results were obtained: Methylphenylfuroxan (cf. *C. A.* **23**, 375), rhombic system, bipyramidal class, $a:b:c$ = 0.59179:1:0.79354. 4-Methyl-5-phenyl-1,2,3,6-dioxdiazine, Me-C:N.O.O.N:CPh (cf. *C. A.* **23**, 375), monoclinic, prismatic class, $a:b:c$ = 1.36827:1:-0.506001. Methyl-*p*-methoxyphenylfurazan, MeC:N.O.N:CC$_6$H$_4$OMe-*p* (cf. *C. A.* **23**, 3665), monoclinic system, prismatic class, $a:b:c$ = 1.6524:1:1.15384. Methyl-*p*-methoxyphenylfuroxan, MeC:N(:O).O.N:CC$_6$H$_4$OMe (cf. *C. A.* **23**, 375), monoclinic system, prismatic class, $a:b:c$ = 1.76427:1:1.52736. 4-Methyl-5-*p*-methoxyphenyl-1,2,3,6-dioxdiazine, MeC:N.O.O.N:CC$_6$H$_4$OMe-*p* (cf. *C. A.* **23**, 375; **24**, 845), triclinic system, pinacoidal class, $a:b:c$ = 1.299:1:0.9539. Diphenylfurazan, PhC:N.O.N:CPh (cf. *Ber.* **22**, 715(1889), rhombic system, rhombic bipyramidal class, $a:b:c$ = 0.81644:1:-0.27766. Diphenylperoxide (4,5-diphenyl-1,2,3,6-dioxydiazine), PhC:N.O.O.N:CPh (cf. *Gazz. chim. ital.* **36**, ii, 103(1906)), monoclinic system, prismatic class, $a:b:c$ = 2.-4803:1:1.0698. α-Phenylperoxide (phenylhydroxyiminoacetic acid nitrile oxide), PhC(:NOH)CNO (cf. *C. A.* **17**, 2268, 3875, 3876), triclinic system, pinacoidal class, $a:b:c$ = 1.7463:1:0.66613. β-Phenylperoxide (5-phenyl-1,2,3,6-dioxdiazine)(cf. *C. A.* **20**, 1085) triclinic system, pinacoidal class, $a:b:c$ = 1.5918:1:1.0314. The results confirm anew the structural formulas previously assigned to the various pairs of isomeric peroxides (cf. *C. A.* **17**, 3875, 3876; **18**, 1491; **20**, 1085; **21**, 1976). The 2 peroxides obtained by dehydrogenation of the asym. glyoximes ArC(:NOH)C(:NOH)Me crystallize in different systems. In the series in which it was possible to measure all the members (the 2 peroxides and the corresponding furazan) only 1 of the 2 peroxides is isomorphous with the furazan (monoclinic), *viz.*, the one to which has been assigned the furoxan (furazan oxide) structure. The similarity in the cryst. forms would accordingly depend upon the presence in each compd. of the penta-atomic ring C_2N_2O characteristic of furazans. On the contrary, the other peroxide crystallizes in the triclinic system, though having a habitus similar to that of the corresponding furoxan and furazan, probably because of the presence of the same lateral chains in the 2 compds. The furazans and furoxans crystallize in systems of higher symmetry than do the corresponding dioxdiazines. Since diphenylfurazan is rhombic and diphenyl peroxide is monoclinic, the latter should have a dioxdiazine structure, and this conforms to all its methods of formation. In the monosubstituted deriv. series, the 2 peroxides crystallize in the triclinic system and have similar angles between axes. However, the orientation of the faces is different so that the parametric ratios differ. Evidently in this series the great asymmetry and the disproportion between the lateral chains is such that the compn. and the orientation of the mol. nucleus has little influence on the formation of the cryst. lattice. The crystallographic data follow:

	Furazans RC:N.O.N:CR′		Furoxans RC:N(:O).O.N:CR′	Dioxdiazines RC:N.O.O.N:CR′
R = Me; R′ = Ph	...		rhombic	monoclinic
R = Me; R′ = C$_6$H$_4$OMe	monoclinic	(isomorphous)	monoclinic	triclinic
R = Ph; R′ = Ph	rhombic		...	monoclinic
R = H; R′ = Ph	...		...	triclinic

The data confirm and complete the f.-p. detns., which established the formation of solid solns. between furazans and furoxans and not between dioxdiazines and furazans, and thus showed that only furazans and furoxans show similar structures. C. C. Davis

Relation of quinoxaline to the ammonia system. F. W. BERGSTROM AND R. A. OGG, JR. *J. Am. Chem. Soc.* **53**, 245–51(1931); cf. B. and McAllister, *C. A.* **24**, 4038.—The behavior of quinoxaline (I) as an ammonoglyoxal has been demonstrated by several new reactions. I adds 2 equivs. of $NaHSO_3$, giving the *compd.* $C_8H_6N_2.2NaHSO_3$, needles, decomps. on heating and gives with bases I and a neutral sulfite; acids cause evolution of SO_2. I reacts slowly with H_2SO_3, giving some H_2SO_4 and an amorphous blue solid which was not further investigated. I and PhMgBr give 70% of *dl*-1,2,3,4-tetrahydro-2,3-diphenylquinoxaline, m. 106°; MeMgI gives 50% of the corresponding 2,3-di-Me deriv. This method is suggested for the synthesis of other homologs. I (10 g.), 7 g. anhyd. HCN and 20 cc. abs. EtOH, heated 2 hrs. at 100°, give 30% of *1,2,3,4-tetrahydrodicyanoquinoxaline*, m. 168.5°, decomps. above 200°; *di-Ac deriv.*, m. 93.5°; attempts to sapon. the cyanide were unsuccessful. I is oxidized by $(NH_4)_2S_2O_8$ to 2,3-dihydroxyquinoxaline. Attempts to nitridize I in liquid NH_3 with I or NH_4N_3 were unsuccessful. I reacts with KNH_2, probably in the sense of the Cannizzaro reaction; less than 1 equiv. of KNH_2 gives a viscous, resinous substance; 2 or more equivs. gives fluorubin and a dark tarry substance. Pyrazine did not show any of the above reactions, although it may be considered as an ammonoglyoxal. C. J. WEST

Formation of a heterocyclic ring closed through mercury atoms. L. VECCHIOTTI. *Ber.* **63B**, 2275–6(1930); cf. *C. A.* **25**, 518.—*o*-$C_6H_4Br_2$ and 2% Na-Hg kept 5 hrs. at 120° in petroleum ether and a little AcOEt and filtered (nothing goes into soln.) yielded a magma consisting of metallic Hg, NaBr and a gray substance (I) which, when mechanically sepd. from the Hg, washed free of NaBr with hot H_2O and crystd. from cymene, gave microprisms which did not m. 300° and darkened slightly on warming. Their compn. corresponded to C_6H_4Hg and with boiling AcOH they gave C_6H_6 and *bis(acetoxymercuri)benzene*, does not m. 300°, converted by I-KI into *o*-$C_6H_4I_2$, m. 270°. V. concludes that I has the structure  C. A. R.



γ-Triazines. XVIII. Synthesis of *m*-tolyl-, *p*-tolyl- and benzyldiaminotriazine. A. OSTROGOVICH AND GH. GHEORGHIU. *Gazz. chim. ital.* **60**, 648–64(1930); cf. *C. A.* **24**, 5752.—In a preliminary paper (cf. O., *C. A.* **5**, 2099) a new synthesis of methyldiamino- and phenyldiamino-γ-triazine was described, which involved condensing $H_2NC(:NH)NHCN$ (I) with MeCN and PhCN, resp. The synthesis was not extended to other compds. sufficiently at the time for publication. In the present paper it includes the 4 isomers, *o*-MeC_6H_4CN (II), *m*-MeC_6H_4CN (III), *p*-MeC_6H_4CN (IV) and $PhCH_2CN$ (V). III, IV and V condense readily with I, as do MeCN and PhCN, whereas II formed no trace of the corresponding aryldiaminotriazine under various exptl. conditions tried. In this latter case, II always remained unaltered, and I was transformed into a mixt. of ammeline (diaminohydroxytriazine) (VI) and melamine (triaminotriazine) (VII), the proportions of VI and VII depending upon the conditions. The *picrate* of VI, $C_3H_4N_5O.C_6H_3N_3O_7.H_2O$ (VIII), was prepd. by dissolving VI in hot concd. aq. picric acid (IX) and cooling. To facilitate the soln. of VI in IX, a little $(CO_2H)_2$ may be added, with much better effect than HCl. VIII is golden yellow and m. 266°. It loses its H_2O of crystn. only when it is heated *in vacuo* over P_2O_5 at 140°. These results show that a Me group in the *o*-position to the CN group impedes the condensation with I and consequently the formation of the γ-triazine nucleus. I (2 g.), III (4 cc.) and EtOH (5 cc.), heated 4 hrs. at 220–5° in a sealed tube, dild. with C_6H_6, filtered, the residue dried, finely ground with 3 *N* NaOH, filtered, the residue washed with cold water and then with dil. EtOH, dissolved in hot dil. HCl, cooled, filtered, poured into a slight excess of 3 *N* NaOH, filtered, the residue washed with water and recrystd. from dil. EtOH (1:1) and then from EtOH, yield 18–20% of *m-tolyldiamino-γ-triazine*, *m*-MeC_6H_4-

$C:N.C(NH_2):N.C(NH_2):N$ (X), m. 239–40°. X, dissolved in boiling dil. HCl and cooled, yields the *HCl salt*, m. 265°. A slight excess of hot *N* H_2SO_4 added to X in a min. of dil. EtOH (1:1) and cooled yields the *H_2SO_4 salt* $(C_{10}H_{11}N_5)_2.H_2SO_4.2H_2O$, softens around 254°, m. 260°, loses its 2 H_2O when heated *in vacuo* at 100°. On cooling X and hot aq. IX or adding cold aq. IX to a cold, dil. soln. of a sol. salt of X ppts. the *picrate* of X, pale yellow, m. 267–8° (to a dark red liquid which evolves a gas). X in a min. of boiling glacial AcOH, cooled, ppts. the *diacetate* $C_{10}H_{11}N_5(AcOH)_2$ (XI), softens 130–40°, solidifies above this range and m. 230–2°. Hot aq. XI, let cool, yields *compds.* contg. less AcOH than IX and the compns. of which depend upon the concn. of the soln. of XI. A definite monoacetate could not be obtained. *In vacuo* over soda-lime, XI loses the greater part of its AcOH, *e. g.*, 2.05, 9.88 and 27.29% after 24 hrs., 60 hrs. and 10 days, resp. *In vacuo* at 100° over soda-lime, XI loses 36.87% in wt. after 2 days (37.37%

corresponds to 2AcOH). **X** (0.5 g.) and Ac_2O (15 cc.), warmed carefully until soln. is complete, filtered hot, cooled and the ppt. recrystd. twice from boiling AcOEt, yields *monoacetyl-m-tolyldiamino-γ-triazine*, $C_{10}H_{10}N_6C_2H_3O$ (**XII**), m. 248°. More is obtained (less pure) by evapn. *in vacuo* over soda-lime, or by distn. *in vacuo*, of the filtered liquid. **X**, warmed with Ac_2O (same proportions as in the prepn. of **XII**) and the soln. boiled 15–20 min. after **X** is dissolved, filtered hot, and the filtrate cooled and the ppt. recrystd. from boiling EtOAc, yields *diacetyl-m-tolyldiamino-γ-triazine*, $C_{10}H_9N_6(C_2H_3O)_2$, m. 232–3°. More is obtained by distn. of the filtrate *in vacuo*. I (2 g.), IV (4 cc.) and EtOH (5 cc.), under the same conditions as in the prepn. of **X**, except for the use of Et_2O instead of C_6H_6 in dissolving the reaction mixt., yield after purification from 50% EtOH 25% of *p-tolyldiamino-γ-triazine* (**XIII**), m. 240° (same as that of **X**, but a mixt. of **X** and **XIII** melts lower). The following salts of **XIII** were prepd. in the same way as those of **X**: *HCl salt*, m. 285°. *Sulfate*, $(C_{10}H_{11}N_6)_2.H_2SO_4.3H_2O$, m. 298°. *Picrate*, yellow, m. 269° (to a dark red liquid which decomps.). *Diacetate*, softens around 140°, then solidifies and m. 230–2°, *in vacuo* over soda-lime it loses its AcOH rapidly, *e. g.*, 16.35, 20.33 and 32.21% in 24 hrs., 60 hrs. and 10 days (cf. the rate loss of **XI**). *In vacuo* at 100° over soda-lime the loss is 37.10%. No monoacetate could be obtained. *Monoacetyl-p-tolyldiamino-γ-triazine*, prepd. like **XII**, m. 273–4°. *Diacetyl-p-tolyldiamino-γ-triazine*, prepd. as before, m. 264°. *Benzyldiamino-γ-triazine* (**XIV**) has been prepd. by Elzanowski (cf. *Diss. Fribourg* (Switzerland) 1898) but has not been described elsewhere since. The yield was low and the following method is much better (50% yield). I (2 g.), V (4 cc.) and EtOH (5 cc.), heated 8 hrs. in a sealed tube at 180–90°, Et_2O added, the solid product finely ground with 3 *N* NaOH or KOH (to eliminate most of the hydroxylated cyanuric bases, especially **VI**, which are always formed), filtered, the residue washed with water, dissolved in dil. HCl, filtered if necessary, the filtrate poured cautiously into 3 *N* NaOH, filtered, the residue washed with water and recrystd. from boiling EtOH, yields **XIV**, m. 238–9° (decompn.) (cf. 233° of Elzanowski). The cryst. form described by E. could not be obtained. The soly. of **XIV** in boiling EtOH or MeOH is approx. 2.2 g. in 100 cc. and in EtOH at 22° is 0.9 g. in 100 cc. Its solv. in boiling water is 0.26 g. in 100 cc. **XIV** forms *salts* when dissolved in acids. It is insol. in cold alkalies, but on prolonged boiling in concd. KOH it dissolves with evolution of 1 mol. of NH_3, and formation of *benzyliminoöxotriazine* (**XV**), called phenylacetoguanide by Elzanowski. **XV** will be described more fully in a later paper. The highest yield of **XIV** was 50%, though in earlier expts. yields up to 80–5% had been obtained. Moreover, in using the same method of synthesis to prep. some alkyldiaminotriazines (to be described in a later paper) a max. yield of only 25% of methyldiaminotriazine was obtained from I and MeCN, though in this particular case it had been prepd. before (cf. O., *C. A* 5, 2099) with yields of 55–6%. All this suggested that in the earlier work there was some impurity in the V and MeCN which catalyzed (accelerated) the condensations in the earlier expts. *HCl salt* (**XVI**) of **XIV**, m. 215°, is so sol. in water that its soln. must be evapd. nearly to dryness to cause crystn., but if fuming HCl is added slowly to its concd. aq. soln. it crystallizes. When **XVI** deposited in the presence of a great excess of HCl is recrystd. from water, slight hydrolysis occurs. When, however, **XVI** is dissolved in EtOH and is repptd. with Et_2O, pure **XVI** is obtained. The fact that pure **XVI** is obtained in the presence of a strong excess of HCl shows that in water a di-HCl salt does not exist, and therefore that under ordinary conditions the base is univalent. Attempts to prep. a di-HCl salt from dry HCl gas under various conditions resulted in failure. A mixt. of anhyd. Et_2O (2 vols.), abs. EtOH (1 vol.) and a little glacial AcOH added to cold **XIV** in a little concd. H_2SO_4, let stand with frequent agitation, ppts. a *sulfate* $C_{10}H_{11}N_6.H_2SO_4$, m. 193–203°; recrystd. from hot water it hydrolyzes to the *monosulfate* $(C_{10}H_{11}N_6)_2.H_2SO_4.2H_2O$ (**XVII**), heated *in vacuo* it loses its H_2O of crystn. at 100° and m. 178–83°. Attempts to prep it from **XIV** in 60–70% EtOH and *N* H_2SO_4 (calcd. quantity) gave a partially hydrolyzed *product* which contained less acid than corresponds to **XVII**. On the other hand, addn. of excess of *N* H_2SO_4 to **XIV** in dil. EtOH gives a salt which contains a little more acid than that which corresponds to **XVII**. When this is recrystd. from hot water, further loss of H_2SO_4 through hydrolysis occurs. In general, only with a certain quantity of H_2SO_4 in excess and at certain concns. is it possible to obtain **XVII**. *Picrate* of **XIV**, prepd. like those of **X** and **XIII**, except that it is necessary to add EtOH to facilitate the soln. of **XIV**, is pale yellow, m. 235° (blackening). *Diacetate* of **XIV**, prepd. like those of **X** and **XIII**, softens 130–40°, then solidifies and m. 230°; kept *in vacuo* at room temp. it loses 1 AcOH (28.47% loss in wt. after 24 hrs.), but the remaining AcOH is lost less readily than with the diacetates of **X** and **XIII** (29.48% loss in wt. after 84 hrs. and 29.86% after 10 days). After 2 days *in vacuo* at 100° over soda-lime it loses all AcOH. It hydrolyzes completely in water, and a mono-

acetate could not be obtained. The behavior of the various salts of XIV show that XIV is a little less basic than X and XIII. XIV (1 g.) and Ac_2O (15 cc. of freshly distd.), refluxed until the liquid becomes a cryst. mass, cooled immediately, filtered, the solid washed with AcOEt, and recrystd. from EtOH, yields *monoacetylbenzyldiamino-γ-triazine* (XVIII), m. 239–40°. If instead of stopping the heating as soon as the reaction liquid crystallizes, it is maintained at a gentle boil, the cryst. mass redissolves, and if the boiling is continued for 0.5 hr., the product is distd. *in vacuo* (to remove Ac_2O) and the residue is recrystd. from hot EtOAc, there is obtained *diacetylbenzyldiamino-γ-triazine* (XIX), m. 145°. The difference in the m. ps. of XVIII and XIX is noteworthy when compared with the relatively small differences among the corresponding derivs. of X and XIII. C. C. DAVIS

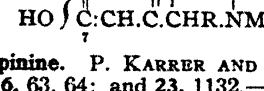
Partial syntheses in the morphine series. I. CLEMENS SCHÖPF AND THEO PFEIFER. *Ann.* **483**, 157–69(1930).—Dihydrothebainone (I) (35 g.) in 300 cc. AcOH treated with 16 g. Br in 150 cc. AcOH at 15° and the residue in 200 cc. H_2O treated with 35 g. KI, gives 43.5 g. of the *HI salt*, m. 215° (decompn.), of *1-bromodihydrothebainone* (II), m. 167°, crystals with 0.5 mol. AcOEt; *HBr salt*, m. 210–5° (decompn.); *oxime*, m. 178–80°. II also results by the reduction of *1-bromodihydrocodeinone* (III), m. 205–7°, with Zn and NH_4Cl in EtOH. III is formed in 75–80% yield by treating I with 2 mols. Br and treating the residue with 7 *N* KOH; from II.HBr in MeOH with Br and

IV

then treating the residue with KOH (80% yield); and by bromination of dihydrocodeinone (IV) in AcOH. Reduction of III in AcOH-AcONa with Pd and H gives quant. IV. While the formation of the phenol group from the O bridge has been accomplished before, this is the first time the reverse reaction has been carried out. In the same way there was prepd. *1-bromodihydrohydroxythebainone*, m. 190–1°; with Br and alkali this gives 75–80% of 1-bromodihydrohydrocodeinone, m. 181–4°; catalytic reduction gives dihydrohydroxycodeinone. 1-Bromosinomenine, m. 188–9° (Goto and Nambo, *C. A.* **24**, 4042), with Br and alkali, give 75% of 1-bromosinomeneine, m. 213° (this is the isobromosinomenine of G. and N.). C. J. WEST

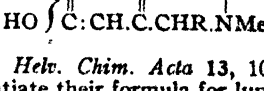
Preparation and properties of dihydrometacodeinone. CLEMENS SCHÖPF AND HERTHA PERREY. *Ann.* **483**, 169–75(1930).—Dihydrometathebainone (thebainol) (I), brominated in MeOH at room temp. and then heated with excess alkali, gives *1-bromodihydrometacodeinone*, m. 241–6°. Catalytic reduction gives quant. *dihydrometacodeinone* (II), m. 196–201°; concd. H_2SO_4 gives a deep red soln.; *oxime*, m. 176–80°; if the oxime formation is carried out at 50°, there results also *metathebainone oxime*, m. 200–3°. II is reduced by Na-Hg to I. II, heated with concd. HCl at 100° for 1 hr. or with 2 *N* NaOH 3 hrs. under the reflux, gives metathebainone. C. J. WEST

Alkaloids of Berberis thunbergii, D. C. var. Maximowiczii, Franch. I. HEISABURO KONDO AND MASAO TOMITA. *Arch. Pharm.* **268**, 549–59(1030).—See *C. A.* **24**, 3512. W. O. E.



Optical rotation of certain cinchona alkaloids. R. DIETZEL AND K. SÖLLNER. *Arch. Pharm.* **268**, 629–36(1930).—The conclusions drawn from the findings obtained in the examn. of quinine, quinidine and cinchonine indicate that a rising content of acid (increase of p_H) is followed by an increase in the optical rotation, which reaches its max. value at a definite p_H. This value remains nearly const. with further addn. of H ion, but finally suffers a gradual fall. The max. optical rotation is reached before 1 acid equiv. is added to the monochloride soln., *i. e.*, before transition of the mono- to the dichloride. The quinoline *N* atom is ionized by the addn. of 1 acid equiv. to the alkaloidal monochloride soln., and parallel with this new ionization an increase in the optical rotation takes place. In certain analogy with these findings observations were made

on the tartrates, from which it appears that tartaric acid possesses in the form of its salts a higher [α] than in its free state; addn. of a strong acid to a tartrate soln. as well as to a soln. of tartaric acid causes diminution in the optical rotation. W. O. E.



Preparation of certain brominated cinchophens. H. G. LINDWALL, J. BANDES AND I. WEINBERG. *J. Am. Chem. Soc.* **53**, 317–8(1931).—5,7-Dibromoisatin (I) is obtained in 80% yield by slowly adding 7.5 g. Br to 3 g. isatin (II) in 40 cc. hot 95% EtOH. II (15 g.), 22.5 g. *p*-BrC_6H_4Ac, 122 cc. EtOH and 60 cc. 33% KOH, refluxed 8 hrs. with stirring, give about 65% of *4'-2-bromo-phenylcinchoninic acid*, pale yellow, m. 239–40°. I and PhAc give the *6,8-di-Br deriv.*, pale yellow, m. 270–1°. I and *p*-$MeOC_6H_4Ac$ give *6,8-dibromo-2-phenyl-4'-methoxycinchoninic acid*, pale yellow, m. 263–4°. II and *p*-$MeOC_6H_4Ac$ give about 65% of 2-phenyl-4'-methoxycinchoninic acid, m. 216°. These Br derivs. will be studied physiologically. C. J. WEST

Neonicotine and isomeric pyridylpiperidines. C. R. SMITH. *J. Am. Chem. Soc.* **53**, 277–83(1931); cf. *C. A.* **18**, 2006.—Details are given for the isolation of *neonicotine* (*β-pyridyl-α-piperidine*) (I) from the reaction product of C_5H_5N, Na and O; I b_{775} 280–1° and yields a *picrate*, m. 213° (cor.); this is probably not identical with nicotimine, isolated by Pictet and Rotschky (*Ber.* **34**, 696(1901)) from the nicotine alkaloids. Reduction of I gives α,β-dipiperidyl, b. 269–70°. Reduction of α,β-dipyridyl gives isoneonicotine (α-pyridyl-β-piperidine), b_{760} 282°, whose picrate m. 217–8° (cor.). *α,α-Pyridylpiperidyl*, b_{755} 265–6°, whose *picrate* m. 187°; the NO deriv. is an oil. Isonicotine (γ,γ-pyridylpiperidine) b_{760} 292°; the picrate m. 215–8° (decompn.); the NO deriv. m. 112°. Nicotidine (β,β-pyridylpiperidine) b. 284–5°; picrate m. about 206°. *β-Pyridyl-γ-piperidine* yields a *picrate*, m. 240°. The ease of reduction by Sn and HCl of the dipyridyls is in the order γ,γ-, β,γ-, α,α- and β,β-, the first being the most easily reduced. C. J. WEST

Constitution of dauricine. HEISABURO KONDO AND ZOICHI NARITA. *Ber.* **63B**, 2420–3(1930); cf. *C. A.* **24**, 122.—It had been found that *m*-hemipinic anhydride and 4,3-MeO(*p*-$HO_2CC_6H_4O$)$C_6H_3CO_2H$ are formed in the oxidative degradation of dauricine, to which was assigned the structure I (R = *p*-$MeOC_6H_4CH_2$). To det. the position of the phenolic HO group, *ethyldauricine ethobromide* (II), from I and EtBr, was subjected to the Hofmann degradation, giving through the methiodide of *α-ethyldauricine-ethylmethine* (III), $EtNMe_2$ and *des-N-ethyldauricine* (IV), oxidized to *4-ethoxy-3,4'-diphenyl ether-1,1'-dicarboxylic acid* (V) by $KMnO_4$ in Me_2CO. The HO group in I must therefore be on C atom 6 or 7, and most probably on 7, since on oxidation C atom 1 is usually easily oxidized off as CO_2. Faltis has recently (*C. A.* **24**, 3513) expressed the opinion that I has perhaps double the above formula, *viz.*, $C_{38}H_{44}O_6N_2$, with an O bridge, but renewed mol.-wt. detns. (Rast) lead K. and N. to retain the formulas $C_{19}H_{23}O_3N$ and $C_{20}H_{27}O_3N$ for I and methyldauricinemethylmethine. II, yellow, decomps. 136–9°; *chloroplatinate*, decomps. 215–8°. III, yellow, optically inactive (0.1965 g. in 10 cc Me_2CO); *methiodide*, yellow, decomps. 162–5°. V, m. 276–9°, was identified by its synthesis from the *4-HO acid*, m. 282° (prepd. from the 4-MeO acid heated with concd. HI in PhOH), refluxed with an excess of EtBr in MeOH.

C. A. R.

Lupinine. P. KARRER AND A. VOGT. *Helv. Chim. Acta* **13**, 1073–7(1930); cf. *C. A.* **16**, 63, 64; and **23**, 1132.—To substantiate their formula for lupinine, K. and V. prepd. optically active anhydrolupinine and lupinane, which is new evidence of the existence of 2 asym. centers in the lupine mol. Treatment of lupinine with $SOCl_2$ gave *chlorolupinane*, b. 124–5°, $[\alpha]_D^{20}$ −32.9° in alc.; this reacted with 33% NMe_3 in alc. at 130–5° to give *lupinanyltrimethylammonium chloride*, $[\alpha]_D^{20}$ −17.9° in alc. The hydroxide prepd. from this with Ag_2O decompd. when heated, giving NMe_3 and anhydrolupinine, b_{15} 86–8°, $d_4^{23.5}$ 0.929, $[\alpha]_D^{23.5}$ −49.8°. Catalytic reduction of this in HCl (Pt oxide) gave lupinane, b. 80–1°, d_4^{23} 0.93, $[\alpha]_D^{23}$ −0.65°; picrate, m. 185°. Another lupinane, b_{15} 84–6°, [α] −9.4° in MeOH (picrate, m. 185°), was obtained by reduction of chlorolupinane with Na and alc. A. WIEBEN

Sparteine. P. KARRER, B. SHIBATA, A. WETTSTEIN AND L. JACUBOWICZ. *Helv. Chim. Acta* **13**, 1292–308(1930); cf. *C. A.* **23**, 1132.—Sparteine, second in importance of the lupine alkaloids, has probably a similar structure to lupinine, and hence 4 possible formulas are advanced, each contg. 2 N atoms in completely satd. ring systems. By repeated application of the Hofmann degradation, each step followed by catalytic

reduction of the unsatd. intermediates, it was hoped to gain an insight into the constitution of sparteine by effecting the removal of the N atoms and by comparing the resulting hydrocarbon with I, II and III, pentadecanes of known structure, since these could result by such a degradation from the above ring systems. *6-Methyl-7-ethyldodecane* (I).—MeAmCHCO$_2$H, b_{18} 121–2°, prepd. from $C_5H_{11}CH(CO_2Et)_2$, was converted by $SOCl_2$ into the acid chloride, b_{737} 179.5–182°, which on treatment with $ZnEt_2$ gave MeAmCHCOEt, b_{738} 191–3°. The tertiary alc. resulting from the action of AmMgBr was dehydrated by $(CO_2H)_2$ to the olefin $C_{15}H_{30}$, b. 236–7°, and reduced by H_2 and Pt in AcOH to I, b_{739} 240–2°, $d_4^{21.9}$ 0.7769, n_D 1.43462, M_D 71.24. *6-Propyldodecane* (II).—The carbinol made by the action of PrMgCl on AmCHO was oxidized with CrO_3 in H_2SO_4 and AcOH to $C_6H_{13}COPr$, b_{731} 202–6°, and converted by AmMgBr into a carbinol which on dehydration with Ac_2O gave the olefin $C_{15}H_{30}$, reduced by H_2 and Pt to II, b_{739} 241–3 $d_4^{18.6}$ 0.7729, n_D 1.43321, M_D 71.41, M_D (calcd. $C_{15}H_{32}$) 71.47. *4-Methyl-6-propylundecane* (III).—PrCHMeCH$(CO_2Et)_2$, b_{11} 120–1°, from the condensation of PrCHMeBr with $NaCH(CO_2Et)_2$, which by processes similar to those used in the prepn. of I was converted into $PrCHMeCH_2COCl$, b_{733} 159–161°. By condensation with PrZnI in the presence of a Zn-Cu couple, the ketone $PrCHMeCH_2COPr$, b_{715} 192–3°, was prepd. which on treatment with AmMgBr gave the tertiary alc. whose olefin $C_{15}H_{30}$, b_{739} 231–3°, was reduced to III, b_{739} 235–6°, $d_4^{18.6}$ 0.7733, n_D 1.43311, M_D 71.36. *Hydrocarbon* (IV) from sparteine By a 6-fold application of the Hofmann degradation, each step being followed by catalytic reduction, a pentadecane of unknown nature, $C_{15}H_{32}$, was formed, b_{739} 242°, $d_4^{18.7}$ 0.7740, n_D 1.43351, M_D 71.35. Comparison of the phys. consts. of the 4 hydrocarbons show that the proposed ring formulas for sparteine cannot be greatly in error, since if the true structure varied greatly from the one proposed, the hydrocarbon IV, isolated in the above manner, would, of necessity, vary more in phys. properties from those of the synthetic hydrocarbons I, II and III. C. R. ADDINALL

An artificial conifer resin acid of the isosylvic acid group. OSSIAN ASCHEN AND O. M. GADD. *Ann.* **483**, 124–32(1930).—Pinabietic acid and HBr in AcOH-Et$_2$O, allowed to stand 4 days, give a mixt. of about 11.6% of the *dihydrobromide* (I), m. 192–4°, and about 15% of the *monohydrobromide* (II), m. 186°; in $CHCl_3$ II adds 1 mol. Br. Boiling I or II with 2 mols. KOH in 90% EtOH for 2 hrs. gives *pinisosylvic acid*, m. 82°; with Ac_2O and H_2SO_4 there results a pale-red color, changing to light brown and finally a violet color. The Na and Ag salts were prepd. Br gives a *tetrabromide*, $C_{20}H_{30}Br_4O_2$, m. 87°. HBr gives I. I, treated with Zn in AcOH on the water bath, gives *dihydroisosylvic acid*, m. 92°; it adds 1 mol. Br but a cryst. dibromide could not be obtained; HBr gives the cryst. *compd.* $C_{20}H_{32}BrO_2$, m. 163–5°. The nitrochloride could not be obtained. C. J. WEST

Higher terpene compounds. XLI. Constitution of santonin. L. RUZICKA AND E. ELSENBERGER. *Helv. Chim. Acta* **13**, 1117–24(1930); cf. *C. A.* **24**, 607.—Catalytic reduction of santonin gives a *hexahydro deriv.*, m. 210–1°, dehydrated by Se to 1-methyl-7-ethylnaphthalene, whose *styphnate* m. 126°. (WITH H. RAMONDT AND A. WICK.) Details are given of the steps for the synthesis of *1,4-dimethyl-6-ethylnaphthalene*, $b_{0.5}$ 115°, *picrate*, m. 85°; *styphnate*, yellow, sinters 74°, colorless at 120°, m. 175°. The behavior on hydration lends support to the formula for santonin of Clemo, Haworth and Walton, *C. A.* **24**, 4046. C. J. WEST

Chlorophyll. XIV. Transformation of pheophorbides into phylloerythrin. H. FISCHER AND OSKAR SÖS. *Ann.* **482**, 225–32(1930); cf. *C. A.* **25**, 520.—Pheoporphyrin a_5 and a_4, with AcOH-HBr at 50–5°, give phylloerythrin, identical with that isolated from bile. Its Me ester m. 266°. The yields are 35–40%. C. J. WEST

Preliminary work to the ring syntheses of porphyrins, etc. III. Several pyrrole compounds with amino groups and unsaturated side chains. H. FISCHER AND KARL ZEILE. *Ann.* **483**, 251–71(1930); cf. *C. A.* **24**, 5302.—2,4-Dimethyl-3-amino-5-carbethoxypyrrole (I) yields an *Ac deriv.*, m. 201° (60% yield). With iso-AmNO$_2$, I gives 90% of the *diazonium chloride*, decomps. at 173°; it is not completely decompd. by boiling with H_2O for 1 hr.; continued boiling, especially with Cu powder, gives 2,4-dimethyl-5-carbethoxypyrrole, m. 125°. Hydrolysis of I with 10% NaOH gives *2,4-dimethyl-3-amino-5-carboxypyrrole* (II), which begins to split off CO_2 at 75°; *Ac deriv.*, m. 203° (decompn.). *2,4-Dimethyl-3-aminopyrrole*, m. 127°, results in about 50% yield by warming the moist II at 75°; *Ac deriv.*, m. 205°. The bromination product of the Ac deriv. of I, heated with H_2O, gives nearly quant. *bis(3-acetylamino-4-methyl-5-carbethoxy-2-dipyrryl)methane*, m. 251°, crystg. in different forms from EtOH, Ac_2O and dil. AcOH. With HCO_2H and Fe powder, this yields an amorphous *1,4,5,8-tetramethyl-2,3,6,7-tetraacetylaminoporphin*. II, HCO_2H and HBr, heated 2–3 min., give (*2,4-di-*

methyl-3-aminopyrryl)-2',4'-dimethyl-3'-aminopyrrolenyl)methene tri-HBr salt, decomps over 280°; from H_2O it seps. as violet crystals, from HBr in yellow-red prisms; AcONa gives the *mono-HBr salt*, dark violet needles, m. 234°. 2,4-Dimethyl-3-(β-carboxyvinyl)-5-carbethoxypyrrole (III) and NaOH with a little H_2O, heated over a free flame for 2 hrs. and then dry-distd., give dimethylpyrrole and (2,4-dimethylpyrryl)(2',4'-dimethylpyrrolenyl)methene. $MeNO_2$ adds to 2,4-dimethyl-3-(β-nitrovinyl)-5-carbethoxypyrrole, giving the *compd.* $C_{12}H_{17}O_6N_3$, m. 180°. 2,4-Dimethyl-3-(β-dicyanovinyl)-5-carbethoxypyrrole (IV) and Br give a perbromide, golden yellow, decompd. by H_2O to a *2-bromomethyl deriv.*, m. 258°. IV, MeOH and Br give the *2-carbomethoxy deriv.*, m. 187°; sapon. with 0.1 *N* NaOH by heating 12 hrs. at 85° gives 2 5-dicarboxy-3-formyl-4-methylpyrrole, does not m. 360°; the *di-Me ester* m. 180° (*oxime*, m. 221°; *semicarbazone*, m. 247°). IV and SO_2Cl_2 in Et_2O, followed by hydrolysis with H_2O, give the *2-carboxy deriv.*, does not m. 360°; similarly III gives the *2-carboxy deriv.*, m. 241°; the free *acid* has no m. p. The *Me ester* of III m. 150°. 2,4-Dimethyl-3-formyl-5-carbethoxypyrrole and SO_2Cl_2 give the *2-carboxy-3-chloro deriv.*, m. 260°. 2,4-Dimethyl-3,5-diformylpyrrole (V) and 2,4-dimethyl-3-acetylpyrrole with HBr-EtOH give *(2,4-dimethyl-3-formylpyrryl)(2',4'-dimethyl-3'-acetylpyrrolenyl)methene*, m. 210°. V and cryptopyrrole give with HBr *5,5',3,3'-tetramethyl-4-ethyl-4'-formylpyrromethene-HBr*, thick prisms. 2,4-Dimethyl-5-carbethoxy-3-thioformylpyrrole, for which a method of prepn. is given, gives with SO_2Cl_2 and H_2O *4-methyl-3-formyl-2-carbethoxy-5-carboxylic acid-pyrrole*, m. 169°; *phenylhydrazone*, yellow, m. 235°. C. J. West

Hydrogen transition in cholesterol. Rudolf Schönheimer. *Naturwissenschaften* **18**, 881(1930).—Cholesterol, free from ergosterol, heated to a high temp. forms a substance which acquires antirachitic qualities on irradiation with ultra-violet light (Koch, *et al.*, *C. A.* **24**, 1140), *i. e.*, an ergosterol-like compd. with probably also 3 double bonds. Cholesterol prepns. free from ergosterol and also from dihydrocholesterol (*C. A.* **24**, 2152; **25**, 323–4) again show after heating to 190–220° under 0.01 mm. (N_2) the presence of 1–2% of a satd. sterol (digitonin reaction, neg. Salkowski reaction, m. 119°, *d*-rotatory), probably a dihydrosterol. Small quantities of the cholesteryl ether of Mauthner are also present. It is believed that a dehydration and a hydration of cholesterol take place simultaneously in this reaction. A so far unknown catalyzer seems to play a role in the process. In the organism the same set of reactions may cause the formation of the 2 compds. from cholesterol. B. J. C. van der Hoeven

The cryoscopy of paraldehyde in solutions of NaCl and $BaCl_2$ (Bourion, Rouyer) 2. The photochemical reaction between ethylene iodide and I in CCl_4 solution (Schumacher, Wiig) 3. Structure of an organic molecular compound (Hertel, Klebu) 2. Insect poisons. XI. The constitution and synthesis of the pyrethrins (Staudinger, *et al.*) 15. Hydrocarbons (Fr. pat. 37,096) 22. Synthetic products (alcohols, aldehydes, acids, NH_3) from industrial gases (Fr. pat. 690,091) 21. *o*-Aminoaryl mercaptans (U. S. pat. 1,784,441) 25.

Schmidt, Julius: **Jahrbuch der organischen Chemie. Jg. XV. Die Forschungsergebnisse und Fortschritte im J. 1928.** Vienna: F. Deuticke. 245 pp. M. 24; linen, M. 27.

Hydrocarbons. I. G. Farbenind. A.-G. Fr. 688,713, Jan. 23, 1930. In the thermal treatment of olefins contg. S compds. as impurities, the reaction vessel and the catalyst are made of materials not attacked by H_2S. Thus, the reaction vessel may be made of plated V2A steel and the catalyst may be Si.

Verifying the purity of hydrocarbons. Abraham Esau. Fr. 691,306, Mar. 6, 1930. The purity of hydrocarbons is verified by submitting them to the action of short waves and measuring the variations of temp.

Higher hydrocarbons. Ruhrchemie A.-G. Fr. 690,028, Feb. 15, 1930. Higher hydrocarbons are obtained by submitting gases contg. CH_4, C_2H_4 and C_2H_2 or their homologs to the action of temps. above 900° for a short time and to the action of an electromagnetic field (luminescent discharges or high frequency oscillations). The treatments may be simultaneous or the heat treatment may follow the other.

Unsaturated hydrocarbons. R. G. Wulff. Brit. 334,178, Feb. 25, 1929. For the production of unsatd. hydrocarbons such as C_2H_2, C_3H_4 or allylene, initial materials such as C_2H_6, casing head gas, gas oil, petroleum fractions, carbureted natural gas, C_3H_8 and higher olefins, naphthenes and aromatic hydrocarbons such as benzene or toluene are heated under a partial pressure of less than 1 atm., to a temp. above 815° for a short

time (suitably 5 sec. or less) in a non-ferrous refractory vessel (such as a Carborundum tube contg. pieces of Carborundum, quartz, sillimanite or other suitable refractory material) in the substantial absence of gases contg. free O, and the reaction products are rapidly cooled. Diluents may be used such as Hg vapor, steam, N, CO or H, in which case the reaction may be effected at atm. pressure. App. and various details of procedure are described.

Cyclic hydrocarbons from acetylene. I. G. FARBENIND. A.-G. Brit. 334,203, Feb. 23, 1929. In the production of cyclic hydrocarbons such as products contg. hydrogenated benzene derivs., C_2H_2 or its mixts. with homologs is passed over heated condensation catalysts (such as compds. of Al or of metals, except As, having a sp. gr. above 4.4 and belonging to the second to seventh groups) and the products thus formed are then passed together with H over metallic hydrogenating catalysts. Industrial gas mixts. contg. C_2H_2 and H may be used such as coke-oven gas or gas mixts. obtained by passing coke-oven gas or a mixt. of CH_4 and H through a high tension elec. arc. The condensation may be effected at temps. of 250–500° and the subsequent hydrogenation at 150–250°. Various details of procedure are described.

Apparatus for polymerizing diolefins. I. G. FARBENIND. A.-G. Fr. 689,824, Feb. 13, 1930. The vessels used for polymerizing diolefins are lined with paper, bitumen or a layer of "Devarda" alloy which is itself covered with a nitrocellulose or gelatin varnish to insure easy removal of the product.

Organic oxygen compounds. HENRY DREYFUS. Fr. 689,342, Feb. 3, 1930. Org. O compds., particularly MeOH, are obtained by heating mixts. of H and CO or CO_2 under pressure in the presence of a catalytic mass in which the catalytic metal is present as the sulfide, such as sulfides of Zn, Cu, Pb or Cd, which may be mixed with Cr_2O_3. Cf. *C. A.* 24, 1649.

Sulfonating inorganic and organic materials. PAUL BAUMGARTEN. Ger. 499,571, June 1, 1926. The org. or inorg. material is subjected to the action of anhydro-*N*-pyridinium sulfonic acid, with or without solvent or suspension agent. Numerous examples are given, in which NH_3, NH_4F, CH_2NH_2, alc., PhOH and naphthalene are sulfonated. The pyridine formed is distd. off and reconverted into *N*-pyridinium sulfonic acid for further use.

Aliphatic compounds. HENRY DREYFUS. Fr. 691, 209, Mar. 5, 1930. In making org. compds. contg. O, particularly AcOH from a mixt. of gases contg. CO, *e. g.*, CO and MeOH, by circulating the gases under pressure several times through a heated zone contg. one or more catalysts, *e. g.*, phosphoric acid, the gases are passed over or through wood charcoal, active C or SiO_2 gel to absorb paraffin hydrocarbons, before they are returned to the reaction zone. They may also be passed through a condenser to sep. liquefiable products.

Alcohols from acetylene and steam. I. G. FARBENIND. A.-G. Brit. 334,223, Feb. 23, 1929. C_2H_2 (or a mixt. contg. C_2H_2 and its homologs) is passed together with steam over condensation catalysts (such as ZnO pptd. on silica gel) comprising compds. of Al or of metals other than As having a sp. gr. of over 4.4 and belonging to the second to seventh groups of the periodic system, and the products, without isolation, are then conducted over metallic hydrogenating catalysts such as metals of the Fe group, Cu or Pt, in order to produce alcs. such as EtOH.

Alcohols by hydrogenation of olefin oxides. OSKAR LOEHR (to I. G. Farbenind. A. G.). U. S. 1,787,205, Dec. 30. Olefin oxides of primary structure which correspond to the general formula: $R_1R_2C\overset{\frown}{.O.}CH_2$ wherein R_1 stands for an alkyl or aryl residue and R_2 for a H atom or alkyl, aryl or aralkyl group are readily converted into primary alcs by treating them with H in the presence of catalysts, such as Cu or metals of the eighth group of the periodic system such as Ni, Co, Fe, Pt or Pd in a finely divided state. These catalysts may be used singly or mixed with each other or they may be applied upon an inert carrier such as pumice, $CaCO_3$, silica gel, charcoal and the like. The catalytic effect may be enhanced by the admixture with the catalyst of small quantities of other substances acting as promoters; *e. g.*, by adding small quantities of alk. acting agents to a ppt. of Ni hydroxide before reducing it to Ni. An analogous effect is obtained by the addn. of small quantities of Al_2O_3 or ThO_2. Examples are given of the production of PrOH from propylene oxide, BuOH and *sec*-BuOH from a mixt. of α- and β-butylene oxides and phenethyl alc. from styrene oxide, and various details of the prepn. of catalysts are also given. Temps. of about 170–80° are suitable for the alc.-producing reaction.

Alcohols, aldehydes, ketones, hydrocarbons and hydrogen from vegetable substances. E. L. RIVMAN. Brit. 334,724, July 16, 1929. Vegetable substances such

as wood from foliaceous trees, reeds, straw and grass are boiled with a strong soln. of $Ba(OH)_2$ or $Sr(OH)_2$ or both and the soln. thus obtained is evapd. to dryness together with the ppt. which it contains, followed by dry distn. of the residue, preferably in the presence of superheated steam. C powder may be added before evapn. and inorg. substances such as soda, NaOH or hydroxides or oxides of Ca, Mg, Al, Zn or Fe are preferably added during the boiling. MeOH, acetone, Me Et ketone, acetone oils, etc., may be obtained, and the oils produced may be purified by hydrogenation and rectification. The mixed products may be hydrogenated together to produce a *motor fuel*.

Ethers of polyhydric alcohols. I. G. FARBENIND. A.-G. (Albrecht Schmidt, Hans Lange and Karl Ost, inventors). Ger. 510,423, Nov. 29, 1927. The alcs. are mixed with a metal oxide or hydroxide, *e. g.*, NaOH, in the presence of a little MeOH or EtOH, and the alcoholates so obtained are treated with alkyl halides at a raised temp. and pressure. An example is given describing the prepn. of *pentaethylsorbitol*, b_{10} 185–90°.

Hydroxyalkyl ethers of glycerol. I. G. FARBENIND. A.-G. (Oskar Loehr, inventor). Ger. 510,422, Dec. 19, 1925. These are prepd. by treating glycerol with alkylene oxides at a raised temp. Examples are given.

Preparing aldehydes by oxidation of the methyl group of aromatic hydrocarbons. Z. E. ZINKOV. Russ. 56,541, Oct. 17, 1929. The aldehyde soln. obtained during the oxidation process carried out with the original hydrocarbon is continuously removed from the oxidation app. and is continuously extd. with bisulfite. The hydrocarbon is returned into the oxidizer after having been freed from sulfur.

Amino aldehydes. I. G. FARBENIND. A.-G. Fr. 690,206, Feb. 19, 1930. Amino-aldehyde compds. are prepd. by condensing aldehydes of the C_6H_6, $C_{10}H_8$ or $C_{14}H_{10}$ series contg. in their mol. substitutable atoms of halogen, with amides of acids or their mono-alkyl, aralkyl and aryl derivs., by heating with the addn. of an agent capable of neutralizing the acid, preferably with the addn. of a catalyst and in the presence of an appropriate solvent. The arylamino-aldehyde compds. obtained are converted to the free amino-aldehyde compds. by sapon. Thus, 5-nitro-2-*p*-tolylsulfonamidobenzaldehyde, m. 181–2°, is prepd by heating a mixt. of 5-nitro-2-chlorobenzaldehyde with *p*-toluenesulfonamide in the presence of KOH and Cu_2Cl_2. By sapon. 5-nitro-2-aminobenzaldehyde is obtained. Several other examples are given.

Ketones. MAISON C. DUCHEMIN. Fr. 691,160, May 13, 1929. Ketones are made from impure acids by volatilizing the acids, passing them through coke or other absorbent material to remove impurities and then over catalysts. In this way AcOH contained in crude or partially purified pyroligneous acid is converted to acetone.

Ketones. I. G. FARBENIND. A.-G. (Walter Reppe, inventor). Ger. 510,712, Jan. 22, 1928. See Fr. 667,787 (*C. A.* **24**, 1120).

Amines. I. G. FARBENIND. A.-G. Brit. 334,579, Nov. 1, 1928. Primary and secondary amines are made by conducting the vapor of an alc. (other than a cyclic alc.) together with a primary amine or NH_3 at a raised temp. (but not substantially above 300°) over a hydrogenating metal catalyst (such as Ni on pumice), with or without pressure. Butylamine is made from BuOH and NH_3, ethyl aniline from EtOH and $PhNH_2$, and monoethylcyclohexylamine from cyclohexylamine and EtOH. Cf. *C. A.* **24**, 1866.

Amines. COMPAGNIE DE PRODUITS CHIM. ET ELECTROMETALLURGIQUES ALAIS, FROGES ET CAMARGUE. Fr 36,718, Jan. 26, 1929 Addn. to 673,648 (*C. A.* **24**, 2469). Primary or secondary aliphatic or aromatic or mixed amines are made by heating a mixt. of a primary or secondary alc. with NH_3 or a primary amine in the presence of a hydrogenation catalyst other than Ni, such as Co, Cu or Fe.

Aliphatic amines. I. G. FARBENIND. A.-G. (Otto Nicodemus and Walter Schmidt, inventors). Ger. 510,439, Nov. 28, 1928. See Fr. 685,345 (*C. A.* **24**, 5765).

Nitriles. SCHERING-KAHLBAUM A.-G. (Siegfried Fischl and Hans Steiner, inventors). Ger. 512,226, Nov. 30, 1928. Nitriles are prepd. by treating the NH_4 salts of the corresponding acids with an acid chloride in the presence of a feeble base that is incapable of sapong. the nitrile at a raised temp. Suitable acid chlorides are $POCl_3$, PCl_3 and *p*-toluenesulfonylchloride; suitable bases are pyridine and $PhNMe_2$. Both mono- and di-carboxylic acid nitriles are obtainable by this method. Examples are given.

Esters. I. G. FARBENIND. A.-G. Fr. 689,275, Feb. 3, 1930. Esters of higher fatty acids and polyhydric alcs. are prepd. by introducing the component of lower b. p. in the state of vapor into the component of higher b. p., the latter being heated. Thus, vapors of glycerol heated to 230° are introduced into the fatty acid of olive oil at the same temp.

Esters of borneol and isoborneol. SCHERING-KAHLBAUM A. G. (Fritz Ulffers,

inventor). Ger. 510,429, Mar. 20, 1928. Addn. to 508,093 (*C. A.* **25**, 710). The method of Ger. 508,093 is conducted throughout at a temp. of 0° or less.

Converting the lower-boiling dichloroethylene into the higher-boiling form. I. G. FARBENIND. A.-G. (Fritz C. Fertsch, inventor). Ger. 510,576, June 28, 1928. The lower-boiling $C_2H_2Cl_2$ is vaporized and passed over contact agents at temps. above 300°, to be converted into the higher-boiling form. Gases which do not react with the $C_2H_2Cl_2$ at this temp. may be present.

Amino- and *N*-alkylaminoalkylarylcarbinols. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 512,031, Aug. 23, 1927. The prepn. of these compds. by the catalytic reduction of nuclearly hydroxylated amino- or alkylamino-alkylaryl ketones is effected in alk. soln., suitably with H in the presence of Ni as a catalyst. Examples are given.

Acyl derivatives of *k*-strophanthidin. SCHERING-KAHLBAUM A.-G. (Wilhelm Neumann, inventor). Ger. 510,430, Mar. 9, 1929. See Brit. 323,973 (*C. A.* **24**, 3249).

Acyl derivatives of *k*-strophanthidin. SCHERING-KAHLBAUM A.-G. (Wilhelm Neumann, inventor). Ger. 512,336, Mar. 16, 1929. See Brit. 323,973 (*C. A.* **24**, 3249).

Alkoxy derivatives of 1-aminonaphthalene-8-carboxylic acid cyclic anhydride. RICHARD HERZ and FRITZ SCHULTE (to General Aniline Works). U. S. 1,779,314, Oct. 21. Alkoxy derivs. of 1-aminonaphthalene-8-carboxylic acid cyclic anhydride are obtained by alkylating hydroxy derivs. of 1-aminonaphthalene-8-carboxylic acid cyclic anhydride. The formed alkoxynaphthostyrils can be converted into the corresponding alkoxy derivs. of 1-aminonaphthalene-8-carboxylic acid by treatment with alk. saponifying agents. Details are given of the production of 5-methoxynaphthostyril, which, when crystd. from C_6H_6, m. 223°. When boiled with a 10% NaOH soln. it is converted into 5-methoxy-1-aminonaphthalene-8-carboxylic acid. General mention is also made of the production of 6- and 3-alkoxynaphthostyrils. The free acid such as 5-methoxy-1-aminonaphthalene-8-carboxylic acid may be used together with hydroxy or amino compds. for producing *azo dyes*.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. Fr. 36,990, May 30, 1929. Addn. to 673,825 (*C. A.* **24**, 2757). The products obtained by the condensation of one mol. of α-naphthoquinone or one of its heteronuclear derivs. with one mol. of a 1,3-butadiene hydrocarbon are treated with alk. agents in the absence of agents capable of fixing H, or with acid agents or by heating in the presence or absence of agents capable of fixing H, alone or with solvents or diluents and finally dehydrogenating the products formed. The *1,4-dihydroanthrahydroquinone* the *1,4-dihydroanthraquinone* and their *homologs* and *derivs.* prepd. in this way are stated to be new compds. Cf. *C. A.* **25**, 304.

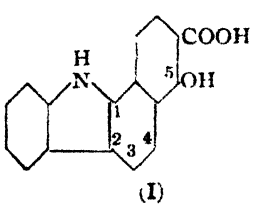
Anthraquinone derivatives. I. G. FARBENIND. A.-G. (Arthur Lüttringhaus, Heinrich Neresheimer, Wilhelm Schneider, Georg Böhner, and Willy Eichholz, inventors). Ger. 504,646, Sept. 13, 1928. Addn. to 494,433 (*C. A.* **24**, 2757) and 502,043 (*C. A.* **24**, 4791). One mol. of benzoquinone is condensed with 2 mols. of a 1,3-butadiene (or with 1 mol. each of two different 1,3-butadienes), the products heated or treated with acid or alk. reagents, and the non-phenolic compds. so obtained are treated with alcoholates or mixts. contg. the same in the absence of dehydrogenating agents. The products are readily convertible into hexahydroanthraquinones. Examples are given.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. (Karl Wilke, inventor). Ger. 510,453, June 22, 1928. Addn. to 464,863. *o*-Aminocarboxylic esters of the anthraquinone series are prepd. by treating anthraquinone-1,2-isoxazole with alk. reagents in the presence of alcs. or phenols. Thus, methyl 1-aminoanthraquinone-2-carboxylate is prepd. by heating the isoxazole with MeOH and KCN. Other examples are given also.

Carbazole derivatives. I. G. FARBENIND. A.-G. (Georg Kränzlein, Heinrich Greune, Franz Brunnträger and Erich Hesse, inventors). Ger. 510,435, Dec. 30, 1926. Neg. substituted carbazoles are prepd. by introducing neg. groups by the customary processes into carbazole-*N*-sulfonic acid, and then splitting off the sulfo group. These steps may be effected in one working operation. Examples are given. Cf. *C. A.* **24**, 2759.

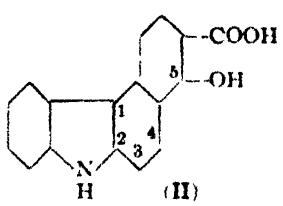
Carbazole derivatives. I. G. FARBENIND. A.-G. (Friedrich Muth and Albert Schmelzer, inventors). Ger. 510,436, Jan. 24, 1929. Substituted carbazolesulfonic acids are prepd. from aminocarbazolesulfonic acids by replacing the NH_2 group by an anion, *e. g.*, OH, halogen, CN, or SH, by way of the diazo group. Examples are given describing the prepn. of (*inter alia*) *1-hydroxycarbazole-3,6,8-trisulfonic acid, 1-hydroxy-8-iodocarbazole-3,6-disulfonic acid, 1,1'-dicarbazoledisulfide-3,3',6,6',8,8'-hexasulfonic acid,*

1-chloro(bromo- or iodo-)carbazole-3,6,8-trisulfonic acid, *1-cyanocarbazole-3,6,8-trisulfonic acid*, and *carbazole-3,6,8-trisulfo-1-arsonic acid*.



Carbazole derivatives. I. G. FARBENIND. A.-G. (Albert Schmelzer, Friedrich Muth and Fritz Ballauf, inventors). Ger. 512,234, Jan. 13, 1928. Hydroxycarbazolecarboxylic acids are prepd. by the action of CO_2 at a raised temp. and pressure on the alkali compds. of hydroxycarbazoles, or on hydroxycarbazoles in the presence of alkali hydroxides or carbonates. Examples are given describing the prepn. of *2-hydroxycarbazole-3-carboxylic acid*, m. 273–4°; *2-hydroxycarbazole-1-carboxylic acid* m. 271–2°; *1-hydroxycarbazole-2-carboxylic acid*, m. 233–4°; and *1,8-dihydroxycarbazole-o,o'-dicarboxylic acid*, m. above 305° (decompn.).

1-Aminocarbazole and its derivatives. I. G. FARBENIND. A.-G. (Friedrich Muth and Albert Schmelzer, inventors). Ger. 512,233, May 15, 1927. The NH_2 group of 1-hydroxycarbazole and of its derivs. is substituted for the OH group by the customary methods. Examples are given. Cf. *C. A.* **25**, 716.



Naphthalene derivatives. I. G. FARBENIND. A.-G. Brit. 334,700, Aug. 28, 1929. *p*-Hydroxyarylaminonaphthalenes are made by treating a 6- or 8-arylamino-2,3-hydroxynaphthoic acid with a *p*-aminophenol in the presence of alkali metal bisulfite, thus effecting replacement of the 2-hydroxy group by arylamino and splitting off of the carboxylic group. Several examples are given. A blue indophenol may be obtained from one of the products described.

Nitrophenyl derivatives of thiazole compounds. JAN TEPPEMA (to the Goodyear Tire and Rubber Co.). Can. 307,701, Jan. 13, 1931. 2-Dinitrophenylbenzothiazyl sulfides are prepd. by heating a dinitrochlorobenzene and mercaptobenzothiazole.

Naphthocarbazole derivatives. I. G. FARBENIND. A.-G. Fr. 689,515, Feb. 6, 1930. Hydroxycarboxylic acids of the naphthocarbazole series are prepd. by treating with CO_2 or combinations thereof hydroxynaphthocarbazoles in the presence of hydroxides or carbonates or bicarbonates of alkali metals or compds. of hydroxynaphthocarbazoles with alkali metals. An example is given of the prepn. of 5-hydroxy-2,1-naphthocarbazolecarboxylic acid of the formula I and 5-hydroxy-1,2-naphthocarbazolecarboxylic acid of the formula II.

(I)

(II)

The 6-hydroxy-2,1- and the 7-hydroxy-2,1- derivs. are also referred to.

Quinoline derivatives. I. G. FARBENIND. A.-G. Brit. 332,911, March 25, 1929, Fr. 689,171, Jan. 31, 1930. 2,4-Diketoquinoline compds. are prepd. by condensing aromatic amines with malonic esters in org. solvents b. above 170° (suitably an excess of the malonic ester itself) and, preferably, distg. off the alc. produced in the reaction as formed. Examples are given of the production of 2,4-diketo-α-naphthoquinoline (from α-naphthylamine and di-Et malonate) and of a 2,4-diketoquinoline methylated in the benzene ring (from *m*-toluidine and di-Et malonate).

Alkali metal ethylates. A. WACKER GES. FÜR ELEKTROCHEMISCHE INDUSTRIE GES. Brit. 334,388, Nov. 24, 1928. See Ger. 505,474 (*C. A.* **24**, 5768).

Catalytic hydrogenation. I. G. FARBENIND. A.-G. Fr. 689,713, Feb. 11, 1930. Carboxylic acid esters contg. at least 2 atoms of C in the mol. (except oxalic esters) are hydrogenated in the carboxylic group by means of very active hydrogenation catalysts such as colloidal SiO_2 and $CuCrO_4$. Examples are given.

Condensation products. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 138,593, July 28, 1928. One mol. of 1,3,3-trimethyl-2-methyleneindoline is condensed with at least 1 mol. of a compd. of the general formula XHC:NH (where X is a univalent residue split off during the reaction) in the presence of Ac_2O. The product forms yellow needles decompg. 240–7°. An example mentions formimidoethyl ether hydrochloride.

Reduction products. I. G. FARBENIND. A.-G. Fr. 690,276, Feb. 6, 1930. Azoxy or azo compds. are obtained by reducing in an alk. medium arylides of nitroarylcarboxylic acids of the formula HO.R.NH.CO.R'.NO_2 in which R and R' are the same or different aryl groups of the C_6H_4 series, and the NO_2 group is *m*- or *p*- to the CO group, and which are capable of coupling in the hydroxyaryl group with diazo compds., and of which at

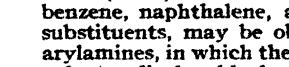
least one *o*- or *p*-position with respect to the OH group is not occupied. Thus, *m'*-nitrobenzoyl-*m*-aminophenol (by heating *m*-nitrobenzoic acid with *m*-aminophenol in PhMe and adding PCl_3) is reduced by *d*-glucose in alk. soln. to an azoxy compd. Other examples are given.

Lactones. GEORG SCHROETER and ALEXANDER GLUSCHKE. Ger. 508,482, Oct. 15, 1926. 2-Bromo-1-keto-1,2,3,4-tetrahydronaphthalene is warmed in alc. soln. with $NaCH(COOMe)_2$, yielding di-Me 1-ketotetrahydronaphthalene-2-malonate. The acid obtained from this by sapon. loses CO_2 when heated, and yields *1-ketotetrahydronaphthalene-2-acetic acid*, m. 97–8.5°, which is then reduced to convert the CO group into CHOH. The product, on warming with HCl, yields *1-hydroxytetrahydronaphthalene-2-acetic acid lactone*, m. 106°. Homologs of this can be prepd. if the 1-ketotetrahydronaphthalene-2-malonic ester is reduced before decarboxylation. 1-Hydroxytetrahydronaphthalene-2-acetic acid lactonecarboxylic acid is then obtained which, after esterification, methylation and sapon. yields *1-hydroxytetrahydronaphthalene-2-propionic acid lactone*, a stereoisomeric compd., m. 140–3° and 82–4°. Hydroaromatic polycyclic lactones can be prepd. similarly from substitution products of 2-halo-1-ketotetrahydronaphthalene, or from the corresponding decahydronaphthalene derivs., or from α-halo ketones derived from other polycyclic hydroaromatic hydrocarbons, *e. g.*, octahydroanthracene and octahydrophenanthrene. Further examples are given describing the prepn. of (*inter alia*) *5-methoxy-1-hydroxy-1,2,3,4-tetrahydronaphthalene-2-acetic acid lactone*, m. 134.5°; *5,8-dimethyl-1-hydroxy-1,2,3,4-tetrahydronaphthalene-2-propionic acid lactone*, m. 117–9°; *1-hydroxy-1,2,3,4,5,6,7,8-octahydroanthracene-2-acetic acid lactone*, m. 174°. Cf. *C. A.* **23**, 5195.

Lactones. GEORG SCHROETER and ALEXANDER GLUSCHKE. Ger. 511,887, Jan. 20, 1928. Addn. to 508,482. The hydroaromatic polycyclic lactones described in Ger. 508,482 (preceding abstr.) are now prepd. by a modified method in which cycloketonyl oxalic acids or their esters are used as starting materials. Thus, 5-ketotetrahydronaphthalene-6-oxalic acid is reduced, yielding 5-hydroxytetrahydronaphthalene-6-oxalic acid which is reduced, yielding 5-hydroxytetrahydronaphthalene-6-glycolic acid, which by prolonged warming with mineral acid undergoes mol. rearrangement to 5-ketotetra hydronaphthalene-6-acetic acid, which is then further treated as described in the prior patent. Examples are given.

Azides. OSKAR MATTER. Ger. 510,420, Aug. 29, 1929. Heavy metal azides are continuously prepd. by supplying to a reaction vessel an alkali azide soln., a heavy metal salt soln., and an aq. soln. inert to the reagents but having a limited solvent power for the products, *e. g.*, AcONa soln. The reaction products are continuously withdrawn.

Thiosemicarbazones of hydroxyarsenobenzenes. KARL STREITWOLF and ALFRED PFIRLE (to Winthrop Chemical Co.). U. S. 1,785,660, Dec. 16. Compds. such as thiosemicarbazones of 1,1'-diformyl-3,3'-dihydroxyarsenobenzene, 1,1'-diformyl-2,2'-diamino-3,3'-dihydroxyarsenobenzene, 1,1'-diformyl-2,2'-dichloro-3,3'-dihydroxyarsenobenzene, 1,1'-dihydroxy-2,2'-diacetylarsenobenzene or 1,1'-dihydroxy-2,2'-diacetyl-5,5'-diamino-4,4'-arsenobenzene (forming relatively stable aq. solns. suitable for *therapeutic uses*) may be prepd. either by subjecting the corresponding hydroxyformylarsonic acids and hydroxyacylarsonic acids to the action of thiosemicarbazones and converting the arsonic acid thiosemicarbazones thus obtained into the arseno compds. by means of a reducing agent, or by first reducing the aldehyde- and ketone-arsonic acids into the corresponding arseno compds., then treating the latter with thiosemicarbazide. In order to obtain the phenolates, the arsenohydroxy thiosemicarbazones thus produced are finally transformed in the usual manner into their Na salts which may be sepd., if required, by a suitable precipitant. The thiosemicarbazones are yellow to yellowish red; they melt with decompn. and readily dissolve in aq. caustic alkalies with formation of the respective alkali metal salts, the so-called phenolates. The latter are yellow to brownish red and readily sol. in water. Their aq. solns. show an alk. reaction and they are much more stable than the solns. of the corresponding carbazones which contain no S.



Halogenated sulfonephthaleins. WILTON C. HARDEN (to Hynson, Westcott & Dunning, Inc.). U. S. 1,786,611, Dec. 30. Di- and tetra-halogenated sulfonephthaleins and their analogs can be prepd. by condensing di- or tetra-halogenated *o*-sulfobenzoic acids or the corresponding anhydrides with various phenols and substituted phenols at temps. of 120° to 170°. The di- and tetra-halogenated *o*-sulfobenzoic acids are prepd. by halogenation of *o*-sulfobenzoic acid, its anhydride, or its acid NH_4 salt, in fuming H_2SO_4 at 60–170°. The condensations are brought about with or without the use of a condensing agent such as, *e. g.*, $SnCl_4$, $ZnCl_2$, H_2SO_4, etc., the conditions depending upon the phenols used. Examples of phenols which have been condensed in

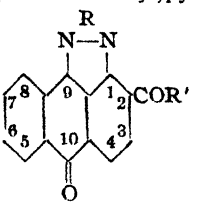
this manner are: phenol, resorcinol, cresols and various substituted phenols such as *o*-chlorophenol and *o*-bromophenol. With *o*-halogenated phenols the resulting condensation product is a di-halogenated phenol di- or tetra-halogenated sulfonephthalein, that is, the halogens are present in the phenolic nuclei as well as in the sulfonephthalein nucleus. Another method of prepg. halogenated sulfonephthaleins contg. halogen in the phenolic nuclei, as well as in the sulfonephthalein nucleus, consists in the direct halogenation of a halogenated sulfonephthalein which contains halogen in the sulfobenzoic acid nucleus. Details are given of the prepn. of phenoltetrabromosulfonephthalein, phenoldiiodosulfonephthalein, dichlorophenoltetraiodosulfonephthalein, diiodoresorcinoltetraiodosulfonephthalein and tetrabromophenoltetraiodosulfonephthalein and mention is made of other related compds. which may be made in similar manner.

Substituted mercaptobenzothiazoles. ADOLPHE H. NEY (to Goodyear Tire & Rubber Co.). U. S. 1,788,585, Jan. 13. In forming a product such as 1-mercapto-3-methyl-5-chlorobenzothiazole, the reaction products of S_2Cl_2 upon an arylamine such as *o*-toluidine are subjected to the action of water and the resulting product is subjected to the action of an alkali such as NaOH and CS_2.

Aminothiazoles. I. G. FARBENIND. A.-G. Fr. 688,867, Jan. 25, 1930. 2-Amino or 2-arylaminobenzothiazoles are prepd. by treating mono- and di-arylthioureas with Cl or agents liberating Cl in the presence of appropriate solvents or suspension agents. The aminothiazoles thus formed may be halogenated, preferably in the presence of a halogenating catalyst. The 2 steps may be combined without isolating the aminothiazoles. Examples are given of the prepn. of 2-amino-4-methyl- (m. 138°), 2-amino-6-ethoxy- (m. 160–163°), 2-amino-4-methyl-6-chloro- (m. 200–205°), 6,7-benzo-2-amino- (m. 259–261°), 2-amino-6-methyl- (m. 142°), 2-amino-3-methyl-2,3-dihydro- (m. 123°), 2-phenylamino- (m. 157–159°), 2-amino-6-bromo- (m. 210–212°), dichloro-4-methyl-2-amino- (m. 250–255°), 6-bromo-4-methyl-2-amino- (m. 215–218°), and dibromo-2-phenylaminobenzothiazole (m. 215–217°). The above may be transformed to mercaptans by heating with a caustic alkali lye.

Compounds of the thiazole series. HANS P. KAUFMANN and MAX SCHUBERT (to I. G Farbenind. A.-G.). U. S 1,787,315, Dec. 30. New compds. contg. S, having probably in their mol. a thiazole ring and corresponding to the general formula

R.S.C(:NH).NH or its tautomeric form wherein R means an aromatic residue of the benzene, naphthalene, anthracene or anthraquinone series, which may contain further substituents, may be obtained by allowing a salt of sulfocyanic acid to act on primary arylamines, in which the *p*-position to the amino group is either substituted by a univalent radical or blocked (as in the case of β-naphthylamine), in the presence of a suitable halogen (Cl or Br) and preferably in an acidic medium. The new thiazole compds. are mostly cryst., having a definite m. p. They possess a basic character, but their amino group is masked in most cases, and they usually yield when diazotized in the usual manner, compds. having only a weak capacity for coupling with the usual azo dye components, but are suitable for use as *intermediates in production of dyes* and *pharmaceutical compds.* Several examples are given. U. S. 1,787,316 relates particularly to the production of a compd., probably 1-amino-5-ethoxybenzothiazole, which is, when dry, a cryst. substance, m. about 163° when recrystd. from dil. alc., and yielding a yellowish diazo compd., from *p*-phenetidine in HOAc by reaction with NaCNS and Br. This compd. when diazotized and coupled with resorcinol forms a red, with H-acid a blue and with 2-naphthol-7-sulfonic acid a reddish violet azo dye. Cf. *C. A.* 23, 2301.



Dehalogenating aromatic compounds. I. G. FARBENIND. A.-G. (Eduard Tschunkur and Fritz Eichler, inventors). Ger. 512,224, Jan. 15, 1927. Aromatic compds. contg. halogen in a side chain are treated with Zn and aq. alkalies or alk. earths, preferably in the warm, whereby the halogen is replaced by H. Thus, benzyl chloride, treated as above, yields toluene and chlorobenzyl chloride yields chlorotoluene.

Aromatic compounds containing both alkoxy and sulfonated aralkyl groups. MYRTIL KAHN and ALFRED THAUSS (to General Aniline Works). U. S. 1,781,981, Nov. 18. A product which in the form of the free acid probably has the formula of a naphthalene deriv., β-$C_6H_{11}OC_4H_3$:$C_6H_3CH_2C_6H_4SO_3H$, being in the form of its alkali metal salt a light colored amorphous substance of soap-like appearance, easily sol. in water to a substantially colorless soln. and having a high wetting action on textile fibers in neutral, alk. and acid solns., and similar new compds. are obtainable by causing aromatic compds. which are substituted by an alkoxy group to react with an aralkyl halide such as benzyl chloride or xylyl chloride, preferably in the presence of a small quantity of a condensing metal and treating the intermediate product obtained with a sulfonating agent. The reaction takes place advantageously at temps.

above 100°, while a hydrohalide is vigorously split off, and, according to the mol. wt. of the starting materials, the new products form more or less viscous, light oils, which are sparingly sol. in alc., but easily sol. in ether, benzene, ligroin and petroleum ether.

Phenolic compounds from benzenesulfonic acids. WM. J. HALE and EDGAR C. BRITTON (to Dow Chemical Co.). U. S. 1,789,071, Jan. 13. In producing products such as phenol by hydrolyzing a benzenesulfonic acid deriv. in aq. alk. soln., diphenyl oxide is added to the reaction mixt. and serves to check further production of diphenyl oxide in the reaction.

Pyrazoleanthrone compounds. HEINZ SCHEYER (to General Aniline Works). U. S. 1,781,248, Nov. 11. In the production of a 2-(dichlorobenzoyl)pyrazoleanthrone or other compds. of the probable general formula

wherein R stands for H or an alkyl radical and R' stands for a residue of an aromatic hydrocarbon which may be substituted by halogen, 1-haloanthraquinone-2-carboxylic acid is at first caused to react with N_2H_4, preferably while heating and in the presence of a diluent such as pyridine. As an intermediate probably 1-hydrazinoanthraquinone-2-carboxylic acid is formed and then ring closure of the hydrazine group occurs, surprisingly with the keto group standing in the 9-position of the anthraquinone nucleus, not with the carboxylic acid group of the 2-position. The pyrazoleanthrone-2-carboxylic acid thus formed is then converted into its acid chloride according to one of the usual methods and the pyrazoleanthrone-2-carboxylyl chloride is condensed with an aromatic hydrocarbon or a halogenated substitution product thereof, in the presence of an acid condensing agent, such as aluminum or iron chloride. The products are *dye intermediates*.

Organometallo mercapto sulfo compounds. WALTER SCHOELLER, ERICH BORGWARDT and ADOLF FELDT (to Chem. Fabrik auf Actien vorm. E. Schering). U. S. 1,784,497, Dec. 9. Compds. of the general formula $X(NHCH_2SO_3Na)(SM)(SO_3y)$ wherein X is an aliphatic, aromatic or heterocyclic radical, M a heavy metal and *y* either H or a metal, preferably an alkali or alk. earth metal, which are employed especially in the form of their water-sol. alkali or alk. earth salts, are produced by the action of formaldehyde bisulfites on amino metallo mercapto sulfonic acids or the salts thereof. The derivs. thus obtained are distinguished by *therapeutic efficiency* and stability, being also nonpoisonous. The new compds. are slightly yellow colored substances which dissolve very readily in water and can be pptd. from such solns. by alc. or MeOH. Examples are given of the production of the compds.: $(NHCH_2SO_3Na)$-$CH_2CH(SAu)(SO_3Na)$, $C_6H_3(SO_3Na)(SAu$ or $SAg)(NHCH_2SO_3Na)$ and $(SO_3Na)(SAu)$-$C_6H_3NHC_6H_3N(NHCH_2SO_3Na)$.

Catalytically hydrogenating aromatic amino compounds. FELIX KLINGEMANN, WILHELM LOMMEL, ERNST KORTEN and THEODOR GOOST (to I. G. Farbenind. A.-G.). U. S. 1,782,729, Nov. 25. In processes exemplified by the production of hexahydroethylaniline from ethylaniline, hexahydrodimethylaniline from dimethylaniline, acetyl-*ar*-tetrahydro-α-naphthylamine from acetyl-α-naphthylamine (and the corresponding β-naphthylamine deriv.), benzoyl-*ar*-tetrahydro-β-napthylamine from benzoyl-β-naphthylamine and 2-amino-*ar*-tetrahydro-3-naphthoic acid from Et 2-acetylaminonaphthalene-3-carboxylate, aromatic amino compds. of the general formula RNX_1X_2 (in which R means an aryl residue of the benzene or naphthalene series, X_1 means H, which may be replaced by alkyl, aralkyl and aryl, and X_2 means alkyl, which may be replaced by aralkyl, or acyl) and H react quickly and smoothly when treated with H in a liquid phase in the presence of a hydrogenating catalyst under pressure. Ni, Co, Cu or mixts. of these metals or oxides thereof, advantageously pptd. on a substratum of large surface, may be used as the hydrogenating catalysts. In the case of the alkyl, aralkyl or aryl derivs. the desired hydrogenated bases are obtained immediately, while in the case of acyl derivs. the acyl group may be removed by saponification, the hydrogenated bases being thus formed.

Nitrogen-containing compounds from acetylene and ammonia, etc. I. G. FARBENIND. A.-G. Brit. 334,193, Feb. 23, 1929. C_2H_2 or aliphatic aldehydes or mixts. of the latter with C_2H_2 or homologs of the latter, in mixt. with NH_3 or amines and with or

without steam, are passed over heated condensation catalysts and the products, without isolation, are passed with H over metallic hydrogenating catalysts. By passing a mixt. of NH_3, C_2H_2 and H at 350° over ZnO and Th oxide on silica gel and then over Ni on silica gel at 150° a condensate may be obtained contg. mainly piperidine and monoethylamine; adding steam increases the proportion of piperidine. NH_3 and acetaldehyde vapor mixed with H and similarly treated yields piperidine and a small quantity of amines. NH_3, C_2H_2, H and vapors of acetaldehyde and ethylamine passed at 400° over ZnO, Th oxide and metallic Cd on silica gel and then at 120° over Ni on silica gel yield ethylamine and piperidines together with small quantities of acetonitrile, propionitrile, pyridine bases and pyrrole derivs. Aniline vapor, C_2H_2 and H passed at 300° over chromic oxide, Al oxide and ZnO on silica gel and then at 200° over Ni on silica gel yield hydrogenated quinolines, mainly tetrahydroquinoline. C_2H_2, H, CH_4 and N mixed with NH_3 and passed at 380° over a mixt. of ZnO and chromic oxide and then at 150° over activated Ni yield ethylamine and acetonitrile. Other hydrogenating catalysts, etc., may also be used.

Concentrating acids. Soc. anon. des distilleries des Deux-Sèvres. Fr 37,056, Mar. 20, 1929. Addn. to 668,935 (*C. A.* **24**, 1651). The process of Fr. 668,935 is applied to the concn. of fatty acids and org. acids in general. Cf. *C. A.* **25**, 116.

High molecular dibasic acids. Pierre M. Baranger. Fr. 679,041, Nov. 27, 1928. Dibasic acids are prepd. by the reaction of esters of acids of high mol. wt. either on C_6H_6, or phenylacetic acid or $C_6H_5CH_2CN$. Examples are given of the prepn. of benzenedihydnocarpic acid, $C_6H_4[(CH_2)_{10}COOH]_2$, $C_6H_4[CH_2COOH][(CH_2)_{10}COOH]$ and $C_6H_4[CH_2CONH_2][(CH_2)_{10}CONH_2]$.

Hydroxyaliphatic acids. Henry Dreyfus. Fr. 36,609, Mar. 27, 1929. Addn. to 671,490 (*C. A.* **24**, 2143). Glycolic acid or other hydroxyaliphatic carboxylic acids are prepd. by submitting oxalic acid or other polycarboxylic aliphatic acids or acid salts of these acids to a catalytic hydrogenation in the presence of a Ni catalyst and in an inert medium. Cf. *C. A.* **24**, 1651.

Anthraquinone-1-carboxylic acids. I. G Farbenind. A.-G. Brit. 334,692, April 11, 1929. Anthraquinone-1-carboxylic acids are made by heating benzanthrone (or its derivs. substituted in the anthrone nucleus) in aq. suspension in the presence of substances having alk. reaction with free O or gases contg. free O to above 180° under pressure. Alk. substances which may be used include: hydroxides of alkali or alk. earth metals or their salts with weak acids such as Na_2CO_3, K_2CO_3 or NaOAc, NH_3 and various org. bases Cf. *C. A.* **24**, 2143.

Haloterephthalic acids. I. G. Farbenind. A.-G. (Hans Schindhelm, inventor) Ger. 512,227, Nov. 12, 1927. *p*-Xylene substituted in the nucleus with 1 or 2 atoms of Cl or Br is treated with Cl or Br under the influence of light, so that the side chains are completely halogenated. The products thus obtained yield haloterephthalic acids when sapond. Thus, 2-chloro-*p*-xylene yields 2-chloroterephthalic acid, and 2,5-dichloro-*p*-xylene yields 2,5-dichloroterephthalic acid. Examples are given.

2-Halo-5-nitroterephthalic acids. I. G. Farbenind. A.-G. (Hans Schindhelm, inventor). Ger. 512,228, Nov. 12, 1927. These are readily prepd. by nitrating monohaloterephthalic acids. Examples are given. *2-Chloro-5-nitroterephthalic acid*, m. 265°, *2-bromo-5-nitroterephthalic acid*, m. 260–2°

Sulfamic acids of secondary bases. I. G. Farbenind. A.-G. (Georg Kränzlein, Heinrich Greune, and Max Thiele, inventors) Ger. 511,525, Dec. 7, 1926. Addn. to 492,024. The method of Ger. 493,024 (*C. A.* **24**, 2759) is modified by using SO_3 instead of $ClSO_3H$.

Acetic acid. British Celanese, Ltd., S. J. Green and E. Handley. Brit 334,207, May 27, 1929. A mixt. comprising formaldehyde (or its condensation products with aliphatic alcs. such as formal) together with CO is heated to 200–450° under high pressure (preferably 100 atm. or more), and the reaction is facilitated by the presence of water, and a suitable catalyst may be used such as H_3PO_4 with Cu or Cu compds. as promoters. A reaction chamber lined with graphite or Au may be used, and the presence in the app. of Fe or other carbonyl-forming metals is avoided, Cu being a suitable metal for lining those portions of the app. in contact with the HOAc formed.

Acetic acid. Henry Dreyfus. Fr. 36,739, Mar. 6, 1929. See Brit. 319,030 (*C. A.* **24**, 2473).

Acetic acid. Soc. française de catalyse généralisée. Fr. 36,719, Jan. 26, 1929. Addn. to 681,958 (*C. A.* **24**, 4306). AcOH is prepd. by passing CO and H over catalysts consisting of different forms of phosphates, silicates and borates of Ni, Co, Cr, Fe and Cu. These may be mixed with metals, oxides or carbonates.

Synthesis of acetic acid and other oxygenated organic compounds. British

CELANESE, LTD., S. J. GREEN and R. HANDLEY. Brit. 334,189, May 27, 1929. HOAc is formed from a mixt. of CO and the vapor of MeOH, passed through a heat exchanger into a reaction chamber contg. a catalyst such as H_3PO_4; and, in general, oxygenated org. compds. may be produced from various starting materials such as CO or its mixts. with H together with MeOH, MeOAc, Me formate or dimethyl ether, by passing over heated catalysts such as those described in Brit. 283,989 (*C. A.* 22, 4133), and the products are freed from undesired condensation products such as paraffin hydrocarbons by the action of absorbents such as active C or silica gel.

Recovery of acetic acid. KURT BRATRING and EMIL ROTH-SCHMIDT. Fr. 689,733, Feb. 11, 1930. AcOH of high percentage is extd. directly from mixts. of acetylcellulose and AcOH resulting from the manuf. of acetylcellulose, by neutralizing the H_2SO_4 used as catalyst, heating the mixt. and pulverizing it in a closed chamber, the AcOH being carried off by hot air or gas from which any acetylcellulose is removed by a dust filter. The AcOH is condensed and the remaining gas used again after reheating.

Arylacetic acids. I. G. FARBENIND. A.-G. Fr. 688,964, Jan. 27, 1930. See Brit. 330,916 (*C. A.* 24, 6031).

Aliphatic anhydrides. HENRY DREYFUS. Fr. 36,747, Mar. 21, 1929. Addn. to 656,901 (*C. A.* 23, 4230). Aliphatic anhydrides, particularly Ac_2O, are made by submitting vapors of aliphatic acids, particularly AcOH, to a thermal decompn. in the presence or not of catalysts. The anhydride formed from the reaction vapors is sepd. by condensation while carrying along the steam by the vapors of one or more liquids the b. p's. of which are between those of the anhydride and the water, *e. g.*, toluene or a xylene. An app. is described.

Aliphatic anhydrides. HENRY DREYFUS. Fr. 36,811, Mar. 20, 1929. Addn. to 634,167. Aliphatic anhydrides are made by passing the vapor of an aliphatic acid over or in contact with a heated catalyst contg. one or more phosphoric acids spread on a support of C, wood charcoal or Carborundum. The temp. used is preferably 400–500° and the vessels are lined with Au, Pt or the like.

Aliphatic anhydrides. HENRY DREYFUS. Fr. 37,089, Mar. 20, 1929. Addn. to 634,167. Higher homologs of Ac_2O are made by the thermal decompn. of the vapors of the corresponding acids in the presence of one or more phosphoric acids The preferred reaction temp. is 400–500°.

Acetic anhydride, etc. H. DREYFUS. Brit. 334,533, June 1, 1929. Ac_2O and other aliphatic anhydrides are made by passing the acid vapor through a heated mass such as Cu turnings (which may be mixed with an alk. earth metal tungstate or other suitable catalysts). Various details and modifications of procedure are described.

Phthalic anhydride. I. G. FARBENIND. A.-G. (Gustav Schneider, inventor). Ger. 512,230, Jan. 1, 1929. Crude phthalic anhydride obtained by the catalytic oxidation of $C_{10}H_8$ is purified by bringing the oxidation products, before condensation, into contact with materials capable of converting the impurities, particularly α-naphthoquinone, into compds. less volatile than the anhydride. Suitably, the oxidation products are passed through fused phthalic anhydride in which a small quantity of a condensing agent, *e. g.*, H_2SO_4 or $AlCl_3$, is dissolved or suspended. Examples are given.

Phthalic anhydride. COMPAGNIE NATIONALE DE MATIERES COLORANTES ET MANUF. DE PRODUITS CHIM. DU NORD, RÉUNIES, ÉTABLISSEMENTS KUHLMANN. Fr. 689,887, Apr. 18, 1929. Crude phthalic anhydride is purified by causing a strong current of air or inert gas to act in or on the surface of the product, preferably kept a few degrees above its m. p., so that the impurities are carried off. The anhydride is then distd. or sublimed. The phthalic acid is recovered from the impurities carried off by the gas.

Bismuth salts of organic arsonic acids. I. G. FARBENIND. A.-G. Brit. 334,449, Nov. 22, 1928. A Bi salt (other than bismuthyl K Na tartrate) such as Bi nitrate is used for prepg. salts by reaction with an alkali metal salt of an acid such as 3-acetylamino-4-hydroxybenzene-1-arsonic acid, *p*-acetylaminobenzenearsonic acid, 3,4-benz(4'-methyl)imidazolonearsonic acid or the formaldehyde-bisulfite compd. of 3-amino-4-hydroxybenzene-1-arsonic acid, in equimol. proportions.

Multivalent metallic salts of half esters of phthalic acid. WM. J. BANNISTER (to Commercial Solvents Corp.). U. S. 1,779,654, Oct. 28. The Zn salt of the Bu half ester of phthalic acid is formed by effecting reaction between BuOH and phthalic anhydride, adding a petroleum hydrocarbon, and neutralizing the resulting product with moist ZnO. In a generally similar manner, there may also be formed various multivalent metallic salts of half esters of phthalic acid with alkyl groups such as Me, Et, Pr, Bu, etc., or aryl groups such as phenyl, tolyl, benzyl or cinnamyl. Multivalent metals such as Zn, Cu, Pb, Fe, Al, Mn, Ni, Co, etc., may be substituted. Although there are some exceptions, the multivalent metallic salts of half esters of phthalic acid are

generally solid, stable, neutral, *resin-like substances*, insol. in water, sol. in org. solvents and exerting a solvent action on nitrocellulose. The Zn and Fe Bu phthalates are plastic solids similar to certain resins in some of their phys. properties, the Zn compd. being colorless and the Fe, reddish brown. The corresponding Cu compd. is a dry powder, bluish green in color.

Multivalent metallic salts of half esters of phthalic acid. WM. J. BANNISTER (to Commercial Solvents Corp.). U. S. 1,779,688, Oct. 28. For the production of the Zn salt of the Bu half ester of phthalic acid, reaction is effected between BuOH and phthalic anhydride in the presence of a solvent such as toluene or a suitable petroleum hydrocarbon material, followed by neutralization with an alkali such as NaOH and reaction with a Zn salt such as $ZnSO_4$. A similar procedure may also be followed in making salts of other half esters and of other multivalent metals such as those generally mentioned in U. S. 1,779,654 (preceding abstract).

Ethylene from acetylene. I. G. FARBENIND. A.-G. Fr. 688,791, Jan. 24, 1930. See Brit. 325,152 (*C. A.* **24**, 3802).

Absorbing propylene in acids. J. W. WOOLCOCK and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 334,228, April 30, 1929. C_3H_6 is absorbed in mixts. of HOAc with H_2SO_4 or with acid isopropyl sulfate (suitably in the presence also of addnl. solvents such as isopropyl alc.) at temps. not exceeding 60°. Isopropyl sulfates and isopropyl acetate are formed and the latter may be recovered by distn. or may be sepd. as a top layer on the addn. of water to the mixt; the sulfuric esters are converted into isopropyl alc. by hydrolysis. C_3H_6 may be sepd. from mixts. by absorbing the higher olefins in cooled 80% H_2SO_4 and then absorbing the C_3H_6 as described (C_2H_4 being substantially unabsorbed). Various details and modifications of procedure are described.

Methanol. ALFRED T. LARSON (to Lazote, Inc., name changed to Du Pont Ammonia Corp. assignor to Canadian Industries, Ltd.). Can. 307,671, Jan. 13, 1931. Methanol is manufd. by passing a gaseous mixt. contg. CO and H, at a pressure of 400–1000 atm. and a temp. of 250–500° over a heated catalyst consisting of the reduction product of a fused mixt. of Cu oxide and an oxide of one of the elements of the group Mn, W, Zn, Cd and Mo.

Methanol. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 689,757, May 9, 1927. MeOH is prepd. by passing a mixt. of CO and H over a catalyst composed of $4ZnO.CrO_3$ at 300–400° and under high pressure. The catalyst is prepd. by suspending ZnO or $Zn(OH)_2$ in water and treating it at ordinary temp. with a slight excess of CrO_3. If the catalyst contains alkali salts higher alcs. are formed.

Synthesis of methanol, etc. I. G. FARBENIND. A.-G. (Mathias Pier, Rudolf Wietzel and Karl Winkler, inventors). Ger. 510,302, Feb. 8, 1924. See Brit. 254,160 (*C. A.* **21**, 2703).

Reactivating catalysts used in methanol synthesis, etc. BRITISH CELANESE LTD., W. BADER and E. B. THOMAS. Brit. 334,251, May 31, 1929. Catalysts such as oxides, *e. g.*, ZnO alone or with metals such as Zn or Cu, employed in the synthesis of MeOH, etc., from CO and H or in like reactions, are reactivated by the action of H or gas mixts. rich in H at temps. higher than those used for the reaction (suitably 370°) and suitably under high pressures such as those employed in the synthesizing reaction (*e. g.*, 100 atm.).

1,3-Butylene glycol. I. G. FARBENIND. A.-G. Fr. 689,002, Jan. 29, 1930. See Brit. 311,671 (*C. A.* **24**, 865).

Acetaldehyde. G. F. HORSLEY and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 334,427, Oct. 21, 1929. Reaction of C_2H_2 with steam is effected (suitably at 300–350°) in the presence of a ZnO catalyst activated by a small proportion of a molybdate or molybdic acid. Various details are described for prepg. and using the catalyst.

Hydrogenating crotonaldehyde to produce butyraldehyde and butyl alcohol. LLOYD C. SWALLEN (to Commercial Solvents Corp.). U. S. 1,788,896, Jan. 13. A mixt. of H and crotonaldehyde in mol. proportion is passed over a reduced Cu silicate catalyst at a temp. of about 170°.

Acetone. HOLZVERKOHLUNGS-IND. A.-G. Fr. 688,437, Jan. 18, 1930. Acetone is prepd. by passing a mixt. of C_2H_2 and steam at a high temp. over contact substances of high activity such as O compds. of heavy metals disposed in thin layers perpendicular to the direction of flow of the reaction gases.

Dihydroxyacetone. I. G. FARBENIND. A.-G. (Karl Böttcher, inventor). Ger. 510,426, Apr. 30, 1926. In isolating dihydroxyacetone from solns. of its alkali bisulfite compds., the latter are decompd. by treatment with a salt of a metal that forms a difficultly sol. sulfite but does not form a stable bisulfite compd. with dihydroxyacetone. $Ba(OAc)_2$ is a suitable salt. An example is given.

Aminosulfonyl chlorides. I. G. FARBENIND. A.-G. Fr. 690,112, Feb. 17, 1930. Aromatic aminosulfonyl chlorides and their ring substitution products are prepd. by the reaction of $ClHSO_3$ on aromatic aminosulfonic acids and their ring substitution products. Thus, 4-chloroaniline-3-sulfonic acid is introduced with cooling into $ClHSO_3$, and gradually heating to 80–90°, whereby the chloride of the acid is obtained. Several other examples and a table of products which can be obtained are given.

β-Hydroxyethyltrimethylammonium monoborate. KARL LÜDECKE. U. S. 1,788,-980, Jan. 13. At least one mol. proportion (but less than 3 mol. proportions) of H_3BO_3 is dissolved in an aq. soln. of β-hydroxyethyltrimethylammonium hydroxide, this soln. is concd. *in vacuo*, the concentrate is redissolved in alc. and the β-hydroxyethyltrimethylammonium monoborate is pptd. from the alc. soln. by a reagent such as acetone. In a modified process, the initial reaction may be effected in alc. soln. Various details of procedure are given.

Benzyl chloride. IMPERIAL CHEMICAL INDUSTRIES, LTD., N. BENNETT, H. DODD, W. C. SPRENT and F. HOLT. Brit. 334,260, June 1, 1929. In the manuf. of benzyl chloride by the action of HCl on crude mixts. contg. benzyl alc. (such as the mixts. recoverable from the manuf. of benzyl cellulose) better yields are obtained by pretreating the mixt. with an alk. substance such as an excess of anhyd. Na_2CO_3. Various details of procedure are described. Brit. 334,261 describes a process in which the crude mixt. contg. benzyl alc. and other products recoverable from the manuf. of benzyl cellulose is treated with Cl, thus forming benzyl chloride and benzaldehyde together with possibly also some benzoyl chloride and nuclear chlorinated derivs., or this treatment may preferably be applied to the residues from benzyl chloride production as described in Brit. 334,260. The production of benzoyl chloride can be avoided by limiting the quantity of Cl used.

2,5-Dichloro-4-aminotoluene. I. G. FARBENIND. A.-G. (Franz Heule and Ernst Hotz, inventors). Ger. 510,306, Mar. 16, 1927. 2,5-Dichloro-4-aminotoluene is obtained, free from isomers, by nitrating 2-amino-5-chlorotoluene in H_2SO_4, diazotizing the nitro deriv. so obtained, exchanging the 2-diazo group for Cl, and reducing the resulting 2,5-dichloro-4-nitrotoluene. The diazotization of the nitrochloroamino compd. should be effected, without isolating the compd., by adding $NaNO_2$ to the nitration mixt after the nitration, and then pouring into water. An example is given.

Chloroxylidines. I. G. FARBENIND. A.-G. (Erwin Hoffa and Erwin Thoma, inventors). Ger. 510,438, Oct 12, 1926. 1-Nitro-2,4-dimethylbenzene is treated with the amt. of Cl or other chlorinating agent required to introduce 1 or 2 atoms of Cl into 1 mol. There is so obtained (1) a mixt., separable by fractional crystn., of *3-chloro-1-nitro-2,4-dimethylbenzene*, m. 46–47°, with *5-chloro-1-nitro-2,4-dimethylbenzene*, m. 42–43°, or (2) *3,5-dichloro-1-nitro-2,4-dimethylbenzene*, m. 79–80°. The products are reduced, yielding *3-chloro-1-amino-2,4-dimethylbenzene*, m. 48–49°, *5-chloro-1-amino-2,4-dimethylbenzene*, m. 98–99°, and *3,5-dichloro-1-amino-2,4-dimethylbenzene*, m. 56–57°. Examples are given.

Phenethyl alcohol. I. G. FARBENIND. A.-G. (K. Brand, inventor). Ger. 504,861, Dec. 4, 1924. The above alc. and its org. acid esters are prepd. by the action of EtNHPh with HNO_2 in a soln. of weak acid such as an org. carboxylic acid. Examples are given.

2,4,6-Tribromoaniline and its acidyl derivatives. BRITISH CELANESE, LTD., and B. F. M. MILLER. Brit. 334,217, May 29, 1929. 2,4,6-Tribromoaniline is purified by sublimation, preferably at 160–5°, and may be treated with AcCl or other acetyl halide or Ac_2O to form substantially pure acyl-2,4,6-tribromoanilides (examples being given of the production of 2,4,6-tribromomonoacetanilide and 2,4,6-tribromodiacetanilide, the last mentioned compd. being suitable for incorporation in compns. of cellulose acetate or other cellulose derivs.).

Dinaphthylene dioxide. I. G. FARBENIND. A.-G. (Josef Binapfl, inventor). Ger. 510,-463, Dec. 16, 1927. 2,2'-Dihydroxy-1,1'-dinaphthyl is treated with O (or gases contg. O) in the presence of an oxide or other compd. of a heavy metal. The reaction may be effected in a solvent, and an org. amine, which acts as an accelerator, may be included in the mixt. The reaction temp. may be 175–85°. Examples are given.

Hydroxythionaphthenes. ERWIN HOFFA and FRITZ MÜLLER (to General Aniline Works). U. S. 1,785,813, Dec. 23. 6-Ethoxyhydroxythionaphthene is made by saponifying at a temp. of between 40° and 70°, 5-ethoxy-2-cyanobenzene-1-thioglycolic acid by the action of H_2O_2 in an alk. soln. so as to form 5-ethoxybenzene-2-carboxamide-1-thioglycolic acid and transforming the latter by the action of an alkali into the 6-ethoxyhydroxythionaphthene, and, in general, hydroxythionaphthenes may be produced by saponifying a cyanoaryl-*o*-thioglycolic acid, $NCRSCH_2COOH$, wherein R stands for an unsubstituted or substituted aromatic hydrocarbon residue, by the action of H_2O_2 in an

alk. soln. so as to form the corresponding arylcarboxamide-*o*-thioglycolic acid, H_2NOC-$RSCH_2COOH$, and transforming the latter by the further action of an alkali into the hydroxythionaphthene.

Hydroxythionaphthenes. I. G. FARBENIND. A.-G. Fr. 36,846, Apr. 27, 1929. Addn. to 652,049 (*C. A.* 23, 3477). In the prepn. of arylcarboxamido-*o*-thioglycolic acids described in Fr. 652,049, org. sulfonic acids, particularly sulfonation mixts. of $C_{10}H_8$ and phenols, are used as sapon. agents.

2-Aminopyridine. SCHERING-KAHLBAUM A.-G. (Curt Räth, inventor). Ger. 510,432, Mar. 8, 1927. 2-Halopyridine is heated with aq. NH_3 in the presence of a catalyst, *e. g.*, $CuSO_4$. Examples are given.

α,α'-Diaminopyridine. KARL PHILIPP (to Pyridium Corp.). U. S. 1,789,022, Jan. 13. Pyridine is added directly to sodamide while the latter is in fused condition.

***C*-Alkylated phenols.** WALTER SCHOELLER, HANS JORDAN and REINHARD CLERC (to Schering-Kahlbaum A.-G.). U. S. 1,788,847, Jan. 13; Ger. 510,442, Oct. 19, 1927. Dihydroxydiphenylmethane is treated with a mixt. of H and an inert gas such as N or water vapor (the water vapor formed in the reaction being suitably left in the reaction mixt.) in the presence of a hydrogenation catalyst, under pressure and at a temp. of about 200°. Examples are given of the production of *p*-isopropylphenol and phenol from di(4-hydroxyphenyl)dimethylmethane and of *m*-cresol and thymol from di(4-methyl-6-hydroxyphenyl)dimethylmethane.

Alkylated phenols. SCHERING-KAHLBAUM A.-G. (Walter Schoeller and Hans Jordan, inventors). Ger. 512,236, Jan. 27, 1928. Addn. to 510,442. The method of Ger. 510,442 (preceding abstr.) is effected in the presence of a "surface catalyst," *e. g.*, fuller's earth or diatomite, on which the hydrogenation catalyst may be pptd.

Extracting *p*-aminophenol from a mixture of compounds obtained in the course of a reaction. M. V. NEVREV and V. S. ROZINA. Russ. 26,475, Apr. 12, 1928. *p*-Aminophenol is sepd. from the mixt. of reaction products obtained in the reduction of *p*-nitrosophenol with iron by the addn. of NaOH, sepn. from the mud, addn. of a weak acid reaction and salting out of the *p*-$HOC_6H_4NH_2.HCl$ by usual methods.

Mono- and di-methylol-*p*-halophenols. I. G. FARBENIND. A.-G. (Max Weiler and Karl Berres, inventors). Ger. 510,447, May 18, 1929. *p*-Halophenols are treated with CH_2O in the presence of an alk. substance. The phenols may contain indifferent substituents, but at least one *o*-position to the OH group must be free. Examples are given describing the prepn. of *2-methyl-4-chloro-6-methylolphenol*, m. 61°, *2,4-dichloro-6-methylolphenol*, m. 70°, *4-chloro-2,6-dimethylolphenol*, m. 165° and *4-bromo-2,6-dimethylolphenol*, m. 150° (decompn.). 2-Methyl-4-bromophenol does not yield methylol derivs. by this method.

Hydroindoleindophenols. FRITZ BALLAUF (to General Aniline Works). U. S. 1,780,058, Oct. 28. Dihydroindole indophenolic compds. are formed by subjecting a dihydroindole of the formula $\overline{R'.NR.CHR.CHR}$ wherein R stands for H, an alkyl, aryl or an arylkyl group and R' stands for a C_6H_6 nucleus which may be substituted by alkyl, aryl, aralkyl, halogen or other univalent group, and an aromatic *p*-aminohydroxy compd. to a reaction leading to the formation of an indophenol. Examples with details of procedure are given for the production of 2-methyldihydroindoleleucoindophenol (from 2-methyldihydroindole and *p*-aminophenol), and of dihydroindoleleucoindophenol, 2-phenyldihydroindoleleucoindophenol, 1,2-dimethyldihydroindoleleucoindophenol and 2-methyldihydroindoleleucodichloroindophenol. These novel leucoindophenols, contg. the dihydroindole nucleus, are usually yellow cryst. substances, easily sol. in water, alc. and H_2SO_4, but much less sol. in salt solns. They form colorless solns. with aq. alkalies, in which the leucoindophenol is easily oxidized, even in contact with atm. O, to the corresponding dark colored indophenols.

***tert*-Butylnaphthol.** FRANZ KOENIGSBERGER (to Dehls & Stein). U. S. 1,788,529, Jan. 13. 4-*tert*-Butyl-β-naphthol is made by mixing together β-naphthol, $AlCl_3$ and *tert*-Bu chloride at room temp., warming gently under a reflux condenser until evolution of HCl ceases, boiling with water and decanting the water, and then distg. *in vacuo*. The product b_8 at about 146° and m. about 102°. Chlorinated and other halogenated derivs. are readily formed from it, and it may be used as a *plasticiser for cellulose derivs.*, as a *dye component*, and for making *pharmaceutical compds.*

Menthol. RHEINISCHE KAMPFER-FABRIK G. M. B. H. Fr. 36,777, Feb. 14, 1928. Addn. to 558,979. See Brit. 285,403 (*C. A.* 22, 4540).

Thymol. RHEINISCHE KAMPFER-FABRIK G. M. B. H. (Karl Schöllkopf and Arthur Serini, inventors). Ger. 511,949, June 2, 1928. See Brit. 312,907 (*C. A.* 24, 865).

Mercaptobenzothiazole. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 690,004,

Feb. 17, 1930. Reactions are carried out continuously by introducing the liquid or liquids under treatment into a pressure chamber from which on completion of the reaction the liquid overflows into a second chamber disposed in the reaction chamber and is drawn off. The app. may be used for prepg. mercaptobenzothiazole from a soln. of S in CS_2 mixed with $PhNH_2$.

Bromomenthane. SCHERING-KAHLBAUM A.-G. Brit. 334,474, Dec. 31, 1928. Menthane is treated with Br in the presence of I as a catalyst.

Caffeine. MONSANTO CHEMICAL WORKS. Brit. 334,741, Oct. 7, 1929. Methyl chloride is used for methylating theobromine or its salts, and when theobromine itself is used a basic substance is added to neutralize the liberated HCl. Various details of procedure are given.

Porphyrins. HANS FISCHER (Paul Halbig, inventor). Ger. 510,433, Mar. 25, 1926. *C*-Tetrasubstituted pyrroles having a CH_2Br group in the α-position and a $COOC_2H_5$ group in the α'-position are heated with acids or water, whereby CH_2Br_2 is split off and dipyrrylmethane derivs. contg. $2COOC_2H_5$ groups are obtained. The corresponding acids, which are easily obtained by sapon., lose CO_2 when heated, yielding porphyrins. Thus, 2-bromomethyl-3-ethyl-4-methyl-5-carbethoxypyrrole, treated as above, yields an isomer of etioporphyrin, while 2-bromomethyl-4-methyl-5-carbethoxypyrrole-3-propionic acid yields isocoproporphyrin. Cf. *C. A.* 20, 2159–60.

Porphyrins. HANS FISCHER. Ger. 511,644, Oct. 9, 1926. Addn. to 510,433 (preceding abstr.). Dipyrrylmethanedicarboxylic acids, prepd. as described in the prior patent, are converted into porphyrins by treatment with acid, particularly HCOOH. Examples are given. Cf. *C. A.* 25, 716.

FRANK P. UNDERHILL

The formation of an enzyme-substrate complex in the system carboxylase–pyruvic acid. YU. V. MEDVEDEV. *Compt. rend. acad. sci. U. R. S. S.* 1930A, 61–6.—Indirect evidence is obtained for the formation of an enzyme-substrate complex ($F'S$) in the system carboxylase-$AcCO_2H$. Insofar as $F'S$ is formed the chem process is retarded, producing the effect of "poisoning." When some of the $F'S$ dissociates, $F'S \longrightarrow F' + S$, the F' concn. increases and consequently the chem. process speeds up. This is the "induction" effect. Expts. were run in which the reaction velocity was measured over a 1-hr. period at 10-min. intervals, sufficient time being allowed at the beginning for all CO_2 from auto-fermentation of the yeast (carboxylase) to be eliminated. The velocity was followed by volumetric detn. of the CO_2 formed. When the amt. of enzyme was the only variant the amt. of poisoning in the initial stages was directly proportional to the resulting relative S concn. When this concn. was high the induction was therefore greater, since after 2.5 hrs. the process reached the same degree of completeness in all cases. The effect of various factors upon the kinetic picture, *i. e.*, upon the $F'S$ concn., was studied. There were (I) slight alterations in the mol. S, *e. g.*, tautomeric modification; (II) change in p_H, 5.5 to 6.8; and (III) addn. of a coenzyme C (boiled yeast broth) both before and after S. The results and conclusions follow: (I) the poisoning effect is greatly lessened by using $AcCO_2Na$ as S, *i. e.*, the compd. $F'S$ is formed only with free $AcCO_2H$. (II) This effect is much smaller at p_H 6.8 than at p_H 5.5, *i. e.*, increase in p_H inhibits formation of $F'S$. (III) C added before S reduces the amt. of poisoning; added after S it does not. C therefore acts by forming a complex CS, but cannot affect $F'S$ if already formed. LEWIS W. BUTZ

Sperma as live fluid crystals. FRIEDRICH RINNE. *Naturwissenschaften* 18, 837–41(1930); cf. *C. A.* 24, 5773.—A review comparing morphological, chem., thermal and optical characteristics of sperma and of fluid crystals. B. J. C. v. D. H.

The position of biology in the scientific thought of this day. OTTO STECHE. *Naturwissenschaften* 18, 841–6(1930). B. J. C. VAN DER HOEVEN

The apparent multiplicity of respiration enzymes. R. P. COOK, J. B. S. HALDANE AND L. W. MAPSON. *Naturwissenschaften* 18, 848(1930).—A suspension of coli bacilli in water satd. with toluene does not oxidize lactic or succinic acid completely as the untreated organism does but burns them to pyruvic and fumaric acids, resp. The 2 reactions were studied at p_H 7.5, also the oxidation of formic acid at p_H 6.3 in Bar-

croft manometers, at 17°, different O_2-CO mixts. being used to find the relative affinities of the Warburg respiration enzyme for these gases. With lactic acid the value of K (approx. the ratio of O_2 and CO affinity) varied from 10.8 to 14.5, av. 12.5 in 6 expts. For formic acid K was 2.67 to 4.72, av. 3.83 in 10 expts. The enzyme-CO compds. are all very little sensitive to light. Conclusion: In the same cell at least 2, probably 3, different respiration enzymes are present; one has the effect of lactic acid dehydrogenase, the other one that of formic acid dehydrogenase. B. J. C. VAN DER HOEVEN

A new sterol in the human brain. IRVINE H. PAGE AND EUGEN MÜLLER. *Naturwissenschaften* **18**, 868(1930).—Crude cholesterol extd. from the brain by acetone was recrystd. twice from EtOH and once from benzine; it gave an almost pure white product, m. 149°. The mother liquors of the recrystns., concd. and freed of crystals, were evapd. to a red-brown sirup; this was sapond. with EtONa and the fatty acids were pptd. with $CaCl_2$. The sterol fraction obtained from the product by ether extn. was white after repeated EtOH recrystn. and hexane recrystn.; it m. 144°. Acetylation and fractional crystn. of the acetyl product gave a small quantity of acetylsterol, crystg. from MeOH in long thin needles; this was different from cholesteryl acetate. The new sterol acetate had a sharp m. p. of 105°, sp. rotation in $CHCl_3$ $\alpha_D^{25} = -25.17°$. Sapon. by EtONa and recrystn. of the sterol gave a product m. 132–5°, rotation in $CHCl_3$ $\alpha_D^{22} = -18.95°$; analysis showed 83.16 C, 12.41 H, *i. e.*, $C_{25}H_{44}O$. No maxima were found in the absorption spectrum above 240 mμ. B. J. C. VAN DER HOEVEN

Determination of the molecular weight of coconut globulin. R. SPYCHALSKI. *Roczniki Chem.* **10**, 630–50 (651 English)(1930).—Two methods of The Svedberg utilizing the measurements of the sedimentation velocity and sedimentation equil. in strong centrifuged fields are described by which mol. wts. of numerous proteins are detd. and a summary is given of all the results obtained by these 2 methods in the Laboratory of Physical Chemistry of the University of Upsala during the past 5 yrs. The mol. wt. of the coconut globulin was detd. by ultracentrifugal methods. This protein is rather unstable, being easily decompd. during the process of prepn. It is a mixt. of 2 main constituents of approx. mol. wt. of 208,000 and 104,000, the larger mols. being present in much greater amt. than the smaller one. The mol. wt. of coconut globulin is considered within exptl. limits, to be the same as that of other oil-seed globulins studied earlier; the smaller mols. represent the first stage of the protein cleavage. J. KUČERA

The effect of split products on enzymic proteolysis. P. RONA, H. KLEINMANN AND E. DRESSLER. *Biochem. Z.* **228**, 6–76(1930); cf. *C. A.* **24**, 5314.—It is again shown that in digestion expts. in which the mixt. is analyzed by a micro-nephelometric method no inhibition of hydrolysis is observed even in the presence of a great excess of hydrolysis products. However, the findings of other observers, who using macro methods have noted a very marked inhibition of hydrolysis in mixts. contg. about 50 times as much substrate and 20 times as much enzyme, have also been corroborated. It is stated that this difference in results is not due to analytical procedures but to the way in which the digestion mixt. is prepd. It is assumed that the combination of the enzyme with the hydrolysis products in the presence of small quantities of enzyme is completely dissociable, but with enzyme concns. beyond this limit the combination begins to exert an inhibiting effect upon further hydrolysis. At a given enzyme concn. an increase in the concn. of split products or a diminution of the substrate concn. equally depresses the hydrolysis. The inhibition in the peptic digestion is entirely different from that in the system casein–trypsin or trypsin–kinase. In this case the results by the micro and macro procedures are also different but they are due to methods of analyses. Where the matter is studied by titrating the hydrolysis products there was always observed an inhibition, but this was never found where the unchanged substrate was measured nephelometrically. In other words, where the primary change in the protein mol. is such that it no longer gives a turbidity with alkaloids, *i. e.*, where the disaggregation by pepsin can be detected, there no inhibition of the process becomes manifest, but the splitting off of COOH groups following the primary disaggregation is definitely inhibited. This sepn. of the digestive process into 2 phases, one of which is inhibited and the other of which is not inhibited, is observable in pepsin but not in trypsin digestion. It still remains, however, as a possibility that even with pepsin it might be practicable to reduce the enzyme concn. to such a low level that the combination will be completely dissociable and the process will not be any longer inhibited. S. M.

Kinetic considerations of the stereochemical specificity of human liver esterase. P. RONA, H. FISCHGOLD AND R. AMMON. *Biochem. Z.* **228**, 77–88(1930).—Optical inversion has been observed in the Me ester of mandelic acid as was already done by

Bamann for the Et ester. This depends entirely upon the substrate concn. The hydrolysis products have no influence on the optical orientation. The mechanism of this inversion has not been discovered, and cannot be elucidated from the viewpoint of interaction of the affinity and hydrolysis consts. of the intermediate reaction products. S. MORGULIS

The influence of sodium monoiodoacetate on the enzymes of zymase and the fermentation of hexosediphosphate. IZUE YAMASAKI. *Biochem. Z.* **228**, 123–6(1930).—The glycolase and the carboxylase enzymes of yeast are little affected by $NaCO_2ClH_2$ in concns. as used by Lundsgaard. The carboxylase, perhaps, is somewhat more affected since the yield of CH_3COCO_2H is only 70% of the control. It is thought possible that the $NaCO_2ClH_2$ inhibits the phosphatese; at any rate, it does not seem to affect the fermentation of hexosediphosphate by the yeast maceration juice. S. M.

The zymatic system of Saccharomyces Johannisberg. IZUE YAMASAKI. *Biochem. Z.* **228**, 127–34(1930).—The presence of glycolase is demonstrated by the formation of methylglyoxal from Mg hexosediphosphate with alc.-ether prepns. of this yeast. The presence of carboxylase is shown by the fermentation of CH_3COCO_2H. Its phosphate esterification capacity is not very great; nevertheless a hexosediphosphate was isolated which showed levulose reactions, so that the mechanism for converting aldose to ketose is effective. S. MORGULIS

The chemical structure of the associated components obtained from gelatin and from gelatin peptone. VII. Fractionation of gelatin peptone and the chemical structure of the fractions. A. FODOR AND CH. EPSTEIN. *Biochem. Z.* **228**, 310–4(1930); cf. *C. A.* **24**, 4312.—A study of one of the gelatin peptone fractions (P III) (cf. *C. A.* **23**, 618, 4956) which is a glycylprolylalanylglycylhydroxyprolylalanine which is isolated from the gelatin peptone treated with Ac_2O. This assocd. component is represented by the structural formula gl—pr—al—gl—oxypr—al. **VIII. The nature of the acetylated peptide associations obtained from gelatin decomposed by glycerol.** *Ibid* 315–26. S. MORGULIS

Studies on the chemical constitution of serum and organ proteins. III. ALFRED BLANKENSTEIN AND ANTON FISCHER. *Biochem. Z.* **228**, 437–42(1930); cf. *C. A.* **24**, 5364.—The importance of using *exactly* neutral $(NH_4)_2SO_4$ in the pptn. of blood proteins is emphasized. Different proteins were also prepd. from kidney, liver and lung which could not be identified as similar or as resembling the proteins of serum and muscle. S. MORGULIS

Oxidation of leuco-methylene blue. ALBERT REID. *Biochem. Z.* **228**, 487–90 (1930).—Sublimed leuco-methylene blue shaken in O_2 with an acetate buffer of p_H 4.5 is oxidized through the catalysis by the Cu present in traces as impurity in the acetate mixts. Added Cu promotes the oxidation while CO reacting with Cu^+ inhibits the oxidation. H_2O_2 is produced in this oxidation. The oxidation does not proceed and is not materially advanced by heavy metals in a phosphate buffer of p_H 7.5 contg. protein, nor is it inhibited either by CO or HCN but is inhibited by narcotics. This indicates that the oxidation of the leuco-methylene blue is a surface phenomenon. S. M.

The natural chemical equilibrium regulative of growth by increase in cell number. FREDERICK S. HAMMETT. *Protoplasma* **11**, 382–411(1930); cf. *Protoplasma* **7**, 297–322(1929); *C. A.* **24**, 4313.—Using the technic previously described, H. tested the effect of a series of S compds. chiefly org. The -SH group was found to be specifically stimulative of cell division. Oxidation products of that group have the opposite effect. M. H. SOULE

Action of several powdered organs upon the amylase of powdered pancreas. A. BADREAU. *J. pharm. chim.* [8], **12**, 20–31(1930).—The following powders were prepd. from defatted materials dried for 4 hrs. in a current of air at 7–9°: salivary glands (ox), mucous membrane of the stomach (hog); pancreas of hog, ox and horse; bile; duodenum (hog). All powders, even the salivary and bile, were decidedly acid to litmus, acidities (cc. of 0.1 *N* NaOH per 1 g.) were, resp., 3, 4.5, 5.5, 6, 6, 2.5, 6.5; p_H was practically uniform: 6 to 6.3. The powd. salivary glands and duodenum were also found to contain amylase. A markedly increased effect upon the amylase of powd pancreas and other amylase-contg. powders by admixt. with other powd. organs whether contg. amylase or not is noted. This effect is not caused by any presence of maltase, but rather by the presence of amino acids in these powders. Peptones rich in amino acids have the same enhancing amylolytic effect, increasing the speed of hydrolysis; hence the *amino acids* may be regarded as the *coenzyme* (Bertrand) necessary to the action of amylase in powd. pancreas. B—METHODS AND APPARATUS

STANLEY R. BENEDICT

The neutral red test in pernicious anemia. S. J. COHEN, M. J. MATZNER AND IRVING GRAY. *Arch. Internal Med.* **46**, 979–83(1930).—A method for the detn. of neutral red in the gastric contents is described. Since other investigations have shown that this dye is secreted in the bile and in some of the intestinal secretions, its presence in the stomach may be due to duodenal regurgitation and therefore does not preclude a diagnosis of pernicious anemia. J. B BROWN

Determination of ammonia and amino acids in urine. A. AGRESTINI AND M. STANGANELLI. *Ann. chim. applicata* 20, 582–8(1930).—In comparing the results of detns. of NH_3 in org. liquids, especially urine, the authors found that the different methods did not always give comparable results. The methods of Schiff-Sörensen and Folin were both found to give low results in the presence of amino acids. To eliminate this difficulty, 40 cc. of soln. was treated with 20 cc. of 7.5% Na_2HPO_4 and 1·2 g. of $MgCO_3.Mg(OH)_2$, and the sides of the beaker were rubbed with a stirring rod After 4 hrs., the ppt. was filtered and the amino acids in the filtrate were detd. on an aliquot by the method of Sørensen. A qual. test with KI and NaOCl was also developed. If to 5–10 cc. of soln. 5–10 drops of 10% KI and a few drops of NaOCl are added, the presence of NH_3 is shown by the appearance of a black color in the soln. The reaction is only sensitive to 1/50,000 but S ion, SH, etc., do not interfere, and the test can be applied to colored solns. A. W. CONTIERI

A micro determination of copper in blood. F. GRENDEL. *Pharm. Weekblad* **67**, 1345–51(1930).—The method, previously described by G. (*C. A.* **24**, 5885), consists in ashing the sample with H_2SO_4, electrodeposition of the Cu, dissolving in HNO_3 and detg. colorimetrically with Et_2NCS_2Na. It is now modified for micro detn. in the blood, where the available sample is 5 cc. or less, representing 0.005–0.015 mg. Cu. The electrolysis is performed in a micro app. with a current of 2–3 v. and 15–30 milliamp. The other modification consists in extg the colored reaction product with CCl_4 and comparing with a standard prepd. in the same manner and contg. 0.015 mg. Cu. Analyses reported are: ox blood, 0.0038 mg. Cu in 5 cc.; horse blood, 0.0044 mg. in 3 cc.; human blood, 0.003 mg. in 4 cc. A. W. DOX

Quantitative estimation of urine sugar via Bertrand. FELIX JÜSTEN. *Arch. Pharm.* **268**, 559–65(1930).—A crit. study of this method inclusive of results obtained with certain modifications in the procedure. W. O. E.

Progress and results in the examination and diagnosis of urine. E. SPAETH. *Arch. Pharm.* **268**, 594–622(1930); cf. *C. A.* **24**, 638.—A digest of recent literature on this subject. W. O. E.

Compilation of certain disturbing factors in the examination of urine. ERNST PFAU. *Apoth. Ztg.* **45**, 1601–2(1930).—The various disturbing influences in the estn. of sugar, blood, pus, AcMe, acetoacetic acid and albumin are noted in tabulated form. W. O. E.

Cell for the measurement of the specific conductivity of the blood serum. WM. R. ASHBY. *Biochem. J.* **24**, 1557–9(1930).—The cell combines large electrodes, with a high resistance, and needs only 1 cc. serum. BENJAMIN HARROW

Stannous chloride as a preventive of the formation of "melanin substance" in the acid hydrolysis of protein. FUJIO NARITA. *J. Agr. Chem. Soc. Japan* **6**, 292–306 (1930); *Bull. Agr. Chem. Soc. Japan* **6**, 23–5.—In the analyses of protein by acid hydrolysis, "melanin substance" interferes with the accurate estn. of amino acids. Hlawetz and Haberman succeeded in preventing the formation of "melanin substance" by means of the addn. of $SnCl_2$. The application of $SnCl_2$ to the detn. of N distribution by Van Slyke's method was tried. The amt. of "melanin substance" could not be expressed by the N value, because tin sulfide, produced on the removal of Sn, adsorbed not merely melanin but also other nitrogenous compds. Arginine, histidine, cystine and tryptophan especially were adsorbed by stannic sulfide. When the formation of "melanin substance" is not large, the protein analysis can be made with good results. Y. KIHARA

The precipitation of uroselectan from its acid solutions at different p_H values. RUGGERO ASCOLI. *Biochim. terap. sper.* **17**, 277–86(1930).—Uroselectan, the Na salt of the 5-iodo-2-hydroxypyridine-*N*-acetic acid, is pptd. from its solns. in urine at a p_H from 4.4 to 4.6. For its use in pyelography, the urine must be of low acidity or neutral. A. E. MEYER

A modification of the apparatus of Folin for the determination of urea in blood. ANTONIO NERI. *Biochim. terap. sper.* **17**, 379–87(1930).—The reaction tube and titration tube are connected on a support in a way that permits them to rest on a water bath. Both tubes carry stoppers perforated by burets with stopcocks, so that the measured liquids may be added without opening the app. The connection is made by a glass tube, all rubber connections being avoided. The first part of this tube forms a serpentine, to permit the sepn. of liquid particles carried along by the air stream. Besides it carries 2 stopcocks; between them, the tube is enlarged and has an opening with a glass stopper. This permits insertion of an azolitmin paper into the tube, when one supposes that the reaction is over and to find out if NH_3 is still passing. A. E. M.

Determination of sulfide sulfur in the stools. J. ST. LORANT AND F. REIMANN. *Biochem. Z.* **228**, 300–9(1930).—Stools are thoroughly mixed and rubbed in a ball mill with the aid of dil. borax soln. An aliquot of the suspension is acidified and freed of its H_2S by drawing air through it. The air is passed through a soln. of Zn acetate wherein the H_2S is absorbed. To prevent the entrance of SO_2 or of O_2, the air before passing through the stool suspension was bubbled through 2 wash bottles contg. KOH and pyrogallol. Fresh stools were preserved in a glass container with 5% borax. The vol. was made up with borax to 750 cc. This was transferred to a porcelain ball mill, washed with 250 cc. of the borax soln. and shaken 20 min. Of the suspension 20 cc. was placed in a large test tube connected to 2 other test tubes, each contg. 20 cc. 10% KOH and 20 cc. 10% pyrogallol. The air passed directly into a graduated cylinder contg. 20 cc. of a soln. of 50 g. Zn acetate, 10 g. Na acetate and 0.05 g. NaCl per l. To the tube contg. the stool suspension 20 cc. 50% H_3PO_4 is added whereupon the aeration is started slowly. Gradually the aeration is increased and is continued for 30 min. The contents of the cylinder are then dild. to 35 cc. with H_2O and 7.5 cc. of a special reagent is quickly added and the cylinder closed. The reagent consists of 1 g. dimethyl-*p*-phenylendiamine sulfate dissolved in 100 cc. H_2O in a 2 l. vol. flask and at once treated with 400 cc. purest H_2SO_4, sp. gr. 1.71. The soln. is cooled and made up to vol. Then, just as quickly, are added 2 cc. of a soln. contg. 25 g. ferric NH_4 sulfate and 5 cc. of the H_2SO_4 in 200 cc. The color due to the formation of methylene blue attains a max. in a few seconds and does not change any longer. The colorimetric reading is made after 1 hr. One cc. of alc. is added and the vol. is adjusted exactly to 50 cc. Data on the H_2S content of feces on different diets are recorded in this paper. S. MORGULIS

The staining of calcium. G. R. CAMERON. *J. Path. Bact.* **33**, 929–55(1930); cf. *C. A.* **24**, 5326.—$AgNO_3$ is not a test for Ca or phosphate, the black reaction is given by a variety of solid deposits of which the anion is more important than the metal. Alizarin is a nearly sp. stain for Ca. It reacts readily *in vitro* and *in vivo* with recently deposited Ca phosphate or carbonate, normal or pathol. but often fails to stain older deposits. Hemotoxylin does not stain Ca salts though it often identifies areas favorable to the deposition of Ca. The reaction obtained in these areas depends partly on the presence of Fe but mostly on a peculiar ground substance which is normally present in bone and cartilage, which if mordanted with Al or Cr stains deeply with hemotoxylin.
J. T. MYERS

A micro determination of copper with urobilin. A. EMMERIE. *Chem. Weekblad* **27**, 552–4(1930).—Urobilin, which is best prepd. by the method of Terwen (cf. *C. A.* **19**, 3501), gives in the presence of NH_4OH with small amts. of Cu colors varying from yellow to red. Quantities from 0.01 to 0.0001 mg. can be detected colorimetrically. For the detn. of small quantities of Cu in biol. material the org. part is destroyed with H_2SO_4 and HNO_3 and the Cu pptd. electrolytically. Ag and Au do not influence the detn. but Hg does. If the latter is present KI is added KI prevents the color reaction with Hg. When both Ag and Hg are present the ppt. of AgI is dissolved with $Na_2S_2O_3$.
E. SCHOTTE

Mechanism of the Liebermann-Burchard reaction. Application to the differentiation between sterols of animal or of vegetable origin. K. MEESEMAECKER AND H. GRIFFON. *J. pharm. chim.* [8], **11**, 572–80(1930).—The reaction consists in an emerald-green color produced in a $CHCl_3$ soln. of cholesterol, phytosterol or ergosterol upon addn. of Ac_2O and H_2SO_4. Variations of this test on the 3 sterols were studied; Ac_2O was replaced by Et_2O, AcOEt, AcCl (then $CHCl_3$ is not needed as a solvent); and H_2SO_4, by $KHSO_4$, P_2O_5, CaO, $ZnCl_2$, $CaCl_2$ Table I of the results indicates certain differences in color reactions between sterols. Table II summarizes the color effects of 18 different org. solvents on the 3 sterols when Ac_2O is retained, together with H_2SO_4, or $KHSO_4$, P_2O_5 and $ZnCl_2$ as dehydrating agents. Different solvents (hydrocarbons and Cl derivs., CS_2, esters, pyridine) give very decided color tests, but MeOH, EtOH and AmOH give no reactions whatever regardless of the dehydrating agent used. Pos. reactions for cholesterol and phytosterol are practically limited to the use of H_2SO_4 or $KHSO_4$. Ergosterol is rich in tests with most of the dehydrators and most solvents. H_2O causes the green color to disappear; after total expulsion of the H_2O, the residue will respond to the test again. With cholesterol and phytosterol, $ZnCl_2$ clearly inhibits the reaction (cf. ergosterol, *C. A.* **24**, 1657); however, when the regular test with cholesterol has reached its max. intensity (30 min.), and then $ZnCl_2$ is added, the tint will keep for 24 hrs.
S. WALDBOTT

A new colorimetric test for the estimation of adrenaline. J. RAE. *Pharm. J.* **125**, 451(1930); cf. *C. A.* **4**, 50, 3253; **7**, 2047; **14**, 2838.—R.'s method applied to tannin (*C. A.* **23**, 356) may be used for adrenaline (*A*). Add 2 cc. of a 10% aq. soln. of NH_4 molybdate to 1 cc. of soln. of *A*-HCl (Brit. Pharm.) in a 50-cc. Nessler tube and dil. with H_2O to 50 cc. The red-brown color develops at once and is permanent for several hrs. Compare it with that of a standard prepd. either with a soln. of *A* of known strength, or with a 1% aq. soln. of pure *tannic acid* previously dried in a desiccator to const. wt. Treat 1 cc. of this soln. with 2 cc. of the reagent and dil. with H_2O to 50 cc. Five cc. of this soln. when dild. to 50 cc. matches exactly the color given by 1 cc. of the official soln. of *A*-HCl, equiv. to 1 mg. of *A*. The test is not interfered with by 1% soln. of cocaine-HCl, kerocaine, stovaine, benzamine lactate, borax and NaCl, satd. soln. of boric acid, chloretone, aq. $CHCl_3$, aqua rosae and aqua sambuci. Reducing substances, *e. g.*, ferrous salts, alc., bisulfites, etc., should be absent. The test cannot be used for the detn. of *A* in urine, as the latter also gives a color with the reagent. Synthetic *A* gives the same depth of color as the natural product. S. WALDBOTT

Method for the determination of peroxidase activity. JOHN D. GUTHRIE. *J. Am. Chem. Soc.* **53**, 242–4(1931).—The method is based on the formation of indophenol from a mixt. of p-$C_6H_4(NH_2)_2$ and α-$C_{10}H_7OH$ in a citrate buffer of p_H 4.5. The substrate consists of 200 cc. of a citrate soln. (21 g. cryst. citric acid and 170 cc. *N* NaOH made up to 1 l.), 200 cc. H_2O, 1 g. p-$C_6H_4(NH_2)_2$.HCl and 20 cc. 4% α-$C_{10}H_7OH$ in 50% EtOH. To this is added, at 25°, 0.5–2.0 cc. of the juice or ext. contg. the enzyme and 5 cc. 0.05 *N* H_2O_2. After 10 min. the reaction is stopped by adding 5 cc. of 0.1 aq. KCN. The indophenol is extd. with PhMe and compared with a standard. The optimum amt. of H_2O_2 is 5 cc. of 0.05 *N* soln. The enzyme activity is linear with the concn. up to an activity of about 4. With potato juice the av. indophenol value was 1.48 mg. with an av. error of ±0.03 mg.

C—BACTERIOLOGY

CHARLES B. MORREY

Carbohydrate and serological determinations of the bipolar gas-forming and non-gas-forming organisms isolated from lymph glands of slaughtered cattle. ONOFRE GARCIA. *Philippine J. Sci.* **43**, 565–75(1930).—Both gas-forming (I) and non-gas-forming (II) bipolar organisms which are morphologically alike were isolated from slaughtered cattle affected with lymphatic adenitis. I fermented glucose, galactose, levulose, maltose, sorbitol, dulcitol, inulin and mannose. II was identified as *P. bovi-septica*. Neither I nor II grew on eosin-methylene blue-lactose agar and each gave definite and distinct biochem. and serological reactions; both I and II are pathogenic for rabbits and guinea pigs. Some immunological phenomena like the early appearance of immunity before antibodies are demonstrable (commonly noted with hemorrhagic septicemia organisms) were observed in the animals injected with I. N. A. LANGE

Azotobacter. P. KALANTARIAN AND A. PANOSSIAN. *Bull. univ. etat R. S. S.-Arménie* No. **5**, 221–4 (in German 224–5)(1930).—K. and P. studied the influence of *Aerobacter aerogenes* upon the biology of *Azotobacter* with reference to N fixation. When starch and sucrose are employed as the source of carbohydrate *Azotobacter* alone or symbiotically with *A. aerogenes* fixes only traces of N in the artificial medium. When mannitol and dextrose are used, the fixation of N by *Azotobacter* in symbiosis with *A. aerogenes* is $1^1/_2$ times as great and with xylose and arabinose 3 times as great as by a pure culture of *Azotobacter*. Since xylose and arabinose are pectin-split products the authors believe that the influence of *A. aerogenes* upon the fixation of N in the soil is of great importance. B. S. LEVINE

The chemistry of the lipoids of tubercle bacilli. XXII. The carbohydrates of the purified wax. E. GILMAN ROBERTS AND R. J. ANDERSON. *J. Biol. Chem.* **90**, 33–43 (1931); cf. *C. A.* **25**, 521.—*d*-Arabinose and traces of glucosamine-HCl and inositol have been isolated from the H_2O-sol. material resulting from the hydrolysis of the purified wax from tubercle bacilli by dil. HCl. If the wax is sapond. with alc. KOH, the Et_2O-sol. constituents are liberated and a complex carbohydrate or polysaccharide remains which on acid hydrolysis yields mannose, *d*-arabinose and galactose and also other, as yet unidentified, reducing sugars. The 3 sugars represent only 55.5% of the polysaccharide. **XXIII. Separation of the lipoid fractions from the timothy bacillus.** ERWIN CHARGAFF, MARY C. PANGBORN AND R. J. ANDERSON. *Ibid* 45–55.—The timothy bacillus is an acid-fast non-pathogenic bacillus belonging to the same class as the pathogenic tubercle bacillus. The following substances from 3173.3 g. of dried bacilli (1602 cultures) have been isolated: phosphatide 0.59, Me_2CO-sol. fat 2.75, polysaccharide 3.90, $CHCl_3$-sol. wax 4.61, yellow wax 0.37, dried bacterial residue 87.70 and pigment 0.05%. The lipoid content of the avian (15.26) and bovine (13.40) is much less than that of human (23.78) tubercle bacilli and the timothy bacillus has the least of all (8.37%). As the lipoids decrease, the amt. of polysaccharide which passes into the alc.-Et_2O ext. increases, the timothy bacillus yielding nearly 4 times as much as the other bacteria. The chem. compn. and biol. reactions of the various lipoid fractions will be compared with corresponding fractions isolated from tubercle bacilli. A. P. LOTHROP

The nucleic acid of the timothy bacillus. ROBERT D. COGHILL. *J. Biol. Chem.* **90**, 57–63(1931); cf. *C. A.* **23**, 1926.—The nucleic acid of the timothy-hay bacillus, *Mycobacterium phlei* (Moeller), on hydrolysis yields guanine, adenine, uracil and cytosine but no thymine and contains at least 20% of pentose. It is, therefore, a plant nucleic acid in sharp distinction to the nucleic acid of the animal type obtained from the supposedly closely related tubercle bacillus. The nucleic acid was extd. from the bacilli, to the extent of approx. 2%. It would seem that such a wide difference in chem. make-up would furnish a much more fundamental basis of classification of bacteria than the older method based on external appearances and staining reactions. A. P. L.

Variation in the fatty acids of Sterigmatocystis nigra as a function of the mineral composition of the culture liquid. CHARLES PONTILLON. *Compt. rend.* **191**, 1148–51 (1930).—Four culture media were prepd. One considered normal contained NH_4NO_3; another was made acid with NH_4Cl; another contained KNO_3 and tended to become alk.; a fourth was made by buffering the normal with $CaCO_3$. At intervals of 2, 3, 4 and 7 days analytical samples were taken. The p_H, the fatty acid content and the dry wt. of the culture as well as the m. p. and I nos. of the fatty acids were detd. The acid culture yielded the least fatty acids. The other yields were about equal although the production was slower in the alk. media. The fatty acids with the highest m. p.

were extd. from the acid culture. The lowest I nos. were obtained from the normal culture. C. M. McCay

Biochemical production of optically active glyceraldehyde. C. Neuberg. *Biochem. Z.* **228**, 259–61(1930).—A method is described for obtaining optically active glyceraldehyde from the racemic compd. by means of *A. aerogenes* and *E. coli*. S. M.

New phosphate ester in lactic acid fermentation. Artturi I. Virtanen and J. Tikka. *Biochem. Z.* **228**, 407–8(1930).—When live *Bact. casei e* ferment glucose 100% of the lactic acid is recovered, Robison's hexose mono-phosphate ester forming an intermediate step. But if the fermentation is carried out with dried bacteria only 50% of the Robison ester is recovered as lactic acid, the other 50% being converted to a new, stable H_2PO_4 ester. S. Morgulis

The chemistry of lipoids of tubercle bacilli. XIX. The composition of the phosphatide fraction isolated from the bovine type of tubercle bacilli. R. J. Anderson and E. Gilman Roberts. *J. Biol. Chem.* **89**, 599–610(1930); cf. *C. A.* **25**, 128.—Hydrolysis of the phosphatide previously isolated from bovine tubercle bacilli, m. 205–8°, yielded from the Et_2O-sol. fraction, 27% palmitic acid, 7% oleic acid, 16% of an optically inactive liquid satd. fatty acid, with which the biol. activity of the phosphatide is associated, and similar to tuberculostearic acid, $C_{18}H_{36}O_2$, and also 5% of a wax-like substance. The water-sol. fraction contained mannose (isolated as phenylhydrazone,) inactive inositol, an org. phosphoric acid similar to glycerophosphoric acid (isolated as the Ba salt), and a mucilaginous substance which caused excessive foaming. The substance also contained 1.0% N and 5.33% ash. **XX. The occurrence of mannose and inositol in the phosphatide fractions from the human, avian and bovine tubercle bacilli.** *Ibid* 611–7.—From 2 to 9 g. of the water-sol. sirup, obtained on hydrolyzing the phosphatide A_3 from human tubercle bacilli, were sepd. 0.82 g. mannose, isolated as phenylhydrazone, 0.80 g. crude inactive inositol, and 0.46 g. of a dried sirup, $[\alpha]_D^{25} = -10.3°$, which contained glucose and a ketose and resembled invert sugar. Further analysis of the water-sol. fraction obtained on hydrolyzing the phosphatide from avian tubercle bacilli (*C. A.* **24**, 1134) yielded mannose and inactive inositol. K. V. T.

The chemical study of bacteria. The presence of *d*-mannose and *d*-arabinose in a complex carbohydrate isolated from the culture medium after the growth of tubercle bacilli. Alice G. Renfrew. *J. Biol. Chem.* **89**, 619–26(1930).—From Long's synthetic medium (*C. A.* **20**, 2535) on which human tubercle bacilli had been cultured for 14 months, was isolated a carbohydrate giving a definite precipitin reaction at 1:1500000 diln., and having $[\alpha]_D^{25} = +32.0°$. It contained 1% reducing sugars before, and 65% after, hydrolysis, and yielded 19.7% of mannose (isolated as phenylhydrazone), and about 10% of *d*-arabinose (isolated as benzylphenylhydrazone), $[\alpha]_D^{25} = +16.1°$ (1:1 CH_3OH and pyridine). Pure *l*-arabinose benzylphenylhydrazone, has $[\alpha]_D^{25} = -16.7°$ (1:1 CH_3OH and pyridine) and the *d*-deriv. in the same solvent $+18.2°$; mixing of the 2 forms lowers the m. p. by 10° (cf. Fischer, Bergmann and Schotte, *C. A.* **14**, 3075). K. V. Thimann

Glucuronic acid, a constituent of the gum of root nodule bacteria. E. W. Hopkins, W. H. Peterson and E. B. Fred. *J. Am. Chem. Soc.* **53**, 306–9(1931); cf. *C. A.* **24**, 5789.—Glucuronic acid has been identified as a constituent of the gum produced by the root nodule bacteria of pea and red clover. The acid was isolated, after hydrolysis of the gum, as the Ba salt and identified as the *p*-bromophenylosazone. Further evidence of the identity of the sugar produced by hydrolysis of the gum with glucose is given. C. J. West

Germicidal action of α-mercapto and α-disulfo soaps. Arnold H. Eggerth *J. Exptl. Med.* **53**, 27–36(1931).—The α-mercapto acids were obtained in the best yields by the action of K xanthate with the α-Br soaps and breaking down the resulting compds by NH_4OH. The disulfo acids were prepd. by oxidizing the mercapto acid in EtOH with I. The following m. ps. are reported for the mercapto and disulfo acids, resp caprylic, both oils; capric, 47°, 37°; lauric, 59°, 48°; myristic, 66°, 56°; palmitic, 72°, 63°; stearic, 80°, 72°. In the α-mercapto series, the soaps with 12 and 14 C atoms are the most germicidal; in the disulfo series, the dicaprate, dilaurate and dimyristate are the most germicidal. The optimum no. of C atoms varies with the test organism used. These soaps, like others previously studied, show a markedly selective germicidal action. C. J. West

Action of testicle, kidney and spleen extracts on the infective power of bacteria. M. Pijoan. *J. Exptl. Med.* **53**, 37–42(1931).—The addn. of testicle ext. to cultures of 20 different bacteria just prior to inoculation enhances their infectious activity to a high degree. Kidney exts. enhance the infections of staphylococci to a less degree

than testicle exts., while spleen exts. never give rise to enhancement and often cause the lesion to be less than would ordinarily be the case. C. J. WEST

THOMAS G. PHILLIPS

Pulsation in the plant. JOH. RICHTER. *Pharm. Zentralhalle* **71**, 789–91(1930).—A description of the *sphygmograph* and its use in demonstrating pulsation in plants, notably the stimulation produced by certain substances like camphor, musk, etc. W. O. E.

Hydrolysis in the living plant by polarized light. ELIZABETH S. SEMMENS. *Bot. Gaz.* **90**, 412–26(1930).—Plants grown in polarized light alone, succeeded by periods of darkness, show (1) disappearance of starch and other reserve products; (2) temporary phototropism; and (3) leaf fall and signs of starvation in whole plant B. H.

Biochemical studies on the bamboo. II. Chemical development in the growth of bamboo shoots. 1. CHOJI TANAKA. *Anniversary Vol. Masumi Chikashige* **1930**, 139–48. (All papers in English.)—Data are given on the content and distribution of H_2O, total and alc.-sol. N, protein, sugar, cellulose, lignin, pentosans and ash in bamboo shoots. **III. Chemical development in the growth of bamboo shoots. 2.** DENYA KAMIYA. *Ibid* 149–59. **IV. Chemical development in the growth of bamboo sheaths.** TAKESUKE TASHIMA. *Ibid* 161–5.—Data similar to those given for bamboo shoots are tabulated. **V. Chemical developments in the growth of bamboo shoots. 3.** KUNITAKA NISHIOKA. *Ibid* 167–73. **VI. The carbohydrates and organic acids of bamboo shoots.** YASUO SASAOKA. *Ibid* 175–81.—*d*-Glucose, *l*-xylose, and glucuronic, oxalic, tartaric, citric and lactic acids were identified in the expressed juice from bamboo culms. An unidentified sugar yielding an osazone of m. p. 188° was isolated and is being investigated. **VII. Seasonal variations in the chemical composition of the madake (Phyllostachys quilioi F. M.).** TORU NAGASAWA. *Ibid* 183–93.—The content of H_2O, ash and total N gradually decreases with age while the fat, cellulose and lignin increase. Reducing sugars reach a max. in Jan. and gradually decrease to a min. in Sept. K. D. JACOB

Physiological studies on Drosera. I. The proteolytic enzyme of Drosera rotundifolia. KUNIO OKAHARA. *Science Repts. Tôhoku Imp. Univ.* [4], **5**, 573–90(1930).—The glycerol ext. of *Drosera* leaves contains a powerful enzyme which in a strong acid medium hydrolyzes proteins to proteoses and peptones. The optimum temp. for its action is about 40° and the optimum acidity is at approx. p_H 1.5. This acidity is rarely known for any other enzymes of plant origin and rather resembles the optimum acidity for pepsin. In this respect *Drosera* enzyme may rank as an animal pepsin. *Drosera* leaves were found to contain HCO_2H. The effect of poisons on the action of this enzyme and of pepsin was studied. When quinine-HCl was added to a mixt. of *Drosera* enzyme and edestin at 39°, so that the concn. of poison in the mixt. was 0.5%, digestion was accelerated; when edestin was added to a mixt. of enzyme and quinine-HCl at 39°, digestion was not affected. In similar tests quinine-HCl was found to repress the digestive action of pepsin. When atoxyl was added to a mixt. of *Drosera* enzyme and edestin (or pepsin and edestin) digestion was accelerated; addn. of edestin to a mixt. of *Drosera* enzyme and atoxyl resulted in acceleration of digestion, whereas addn. of edestin to a mixt. of pepsin and atoxyl resulted in the repression of digestion. LOUISE KELLEY

The other extractives of white leaves of cabbage. I. Animal experiment. JUN-

ICHI OZAKI. *J. Agr. Chem. Soc. Japan* **6**, 633–42(1930).—The white leaves of cabbage do not contain vitamin A, but contain as much vitamin B as do the green leaves of cabbage. Irradiation of the ether ext. of the white leaves by ultra-violet light produced in it an action like that of vitamin D. The nutritive value of the ether ext. was much less than that of triolein. **II. The composition of the oil.** *Ibid* 688–700.—From the ether ext. of white leaves of cabbage, substances insol. in acetone and petroleum ether were removed. A brownish black oil was obtained, which had sapon. value 144.06, acid value 21.24, Hehner value 61.59, I value 103.44, unsaponifiable matter 21.66%, Reichert-Meissl value 2.0. Of the acids of the ether ext. 83.7% were unsatd. Of the satd acids arachidic acid (10%) and palmitic acid (80% or more) were isolated. A small amt. of myristic acid was found; stearic acid was absent. From the unsatd. acid fraction a dihydroxystearic acid (m. 118–9°), an isomer of sativic acid (m. 162–3°), linusic acid (m. 201°) and isolinusic acid (m. 176°) were obtained as the oxidation products by potassium permanganate. Hence an isomer of oleic acid and an isomer of linoleic acid are present. If calcns. are made from the yields of bromination products, hexabromide, tetra and di-bromide, the ratio of the original acids is 1:7.3:1. Therefore, the unsatd. acids consist of linolenic 10%, an isomer of linoleic 75% and an isomer of oleic acid 10% or more. Y. KIHARA

The function of hexuronic acid in the respiration of the cabbage leaf. ALBERT SZENT-GYÖRGYI. *J. Biol. Chem.* **90**, 385-93(1931); cf. *C. A.* **23**, 1423.—"Hexuronic acid plays an important part in the respiration of the cabbage leaf. It connects, as H carrier, the system in which the mol. O_2 enters into reaction with the system which supplies H and is involved in the oxidation of the foodstuff. There is in the cabbage leaf a highly active enzyme, *hexoxidase*, which in the presence of O_2 rapidly oxidized hexuronic acid to its reversible oxidation product." The properties of this enzyme are described. A. P. LOTHROP

The preparation and properties of franguloside (frangulin) from the bark of alder buckthorn of commerce. M. BRIDEL AND C. CHARAUX. *Compt. rend.* **191**, 1151–3 (1930).—The bark of alder buckthorn contains a water sol. enzyme which splits the glucoside of the water ext. with the formation of cryst. frangulin. The pure compd. is prepd. by mixing a kg. of powd. bark with 4 l. H_2O. After 12 hrs. the compd. is extd. with Et_2O. After crystn. from EtOH, it is recrystd. from AmOH and then from a mixt. of pyridine and H_2O (2:1). Yield 25 g. Pale yellow crystals, $C_{21}H_{20}O_9 \cdot H_2O$, $[\alpha]_D$ = —134, m. 246–9°. The glucoside is reduced by the method of Bertrand. Hydrolysis produced 38.8–40% rhamnose. C. M. MCCAY

The presence in a number of vegetables of allantoin with or without allantoic acid, allantoinase and uricase. R. FOSSE, A. BRUNEL, P. DE GRAEVE, P. E. THOMAS AND J. SARAZIN. *Compt. rend.* **191**, 1153–5(1930).—Allantoin has been isolated from the seeds of *Triticum sativum, Hordeum vulgare, Zea mays, Soja hispida, Cicer arietinum, Phaseolus vulgaris* and *Pisum sativum*. It occurs in the roots of *Brassica napus*. Both allantoin and allantoic acid are much higher in newly formed beans than in old ones. Allantoic acid and allantoinase were not found in wheat, barley, corn or in turnips. Uricase was absent in barley, turnips and cauliflower. Cauliflower contained allantoin and allantoinase. It was also rich in allantoic acid. C. M. MCCAY

Physiological-morphological studies on Funaria hygrometrica L. in pure culture. G. SCHWEIZER. *Ber. deut. botan. Ges.* **48**, 75–84(1930).—Spores of *F. hygrometrica* germinated equally well in a series of Detmer solns. made up in agar and adjusted to p_H values varying from 1.56 to 3.19 by the addn. of phosphoric, citric and humus acids. There was also no difference in the growth of the protonema but the formation of leafy shoots was slightly delayed in the more acid media; this difference was no longer apparent after further growth. Moss plants were produced in equal nos. in the various media. The plants in cultures with humus acid formed more antheridia and archegonia than those in the other cultures. The media darkened by humus acid became completely decolorized as growth took place. LAWRENCE P. MILLER

Polar permeability. LEO BRAUNER. *Ber. deut. botan. Ges.* **48**, 109–18(1930). The seed coat of *Aesculus hippocastanum* is about 60% more permeable to water from the outside in than in the opposite direction. There is a potential difference of several millivolts between the two sides of the swollen membrane, the epidermal side being positive. This effect can be explained by the assumption that the testa is composed of an electrolyte-containing double membrane, consisting of 2 layers of varying permeability. The observed potential difference either hastens or retards the movement of water depending upon whether the streaming potential is in the same direction or opposite to that of the membrane. LAWRENCE P. MILLER

Extensibility and turgor tension of cell membranes. H. R. OPPENHEIMER. *Be*

deut. botan. Ges. **48,** 192–206(1930).—The periphery of cells soaked in water and in sugar solns. of various concns. was studied. Strong cell walls prevent any measurable change while in certain less rigid cells changes of 20% were noted. The release of the osmotically extended cell wall does not take place proportionally to the increasing conc. of the outside solns.; it takes place at first more slowly, and then, as the plasmolytic concn. is approached, more rapidly. LAWRENCE P. MILLER

The dependence of the intake of nutrient salts upon the reaction of the substrate. PAUL DAHM. *Ber. deut. botan. Ges.* **48,** 312–6(1930).—An effect of p_H on the intake of nutrient salts by higher plants could not be established by any of the methods used in this investigation. None of these methods, however, was entirely satisfactory LAWRENCE P. MILLER

Changes in the nitrogenous groups of tobacco in the course of roof ripening. A. I. SMIRNOV AND V. P. IZVOSVIIKOV. *Biochem. Z.* **228,** 329–53(1930).—Fasting, which is the first phase in the drying of tobacco leaves, occasions the following alterations in the N products. The protein content diminishes considerably, much more in the protein-rich young leaves than in full-grown leaves. Likewise the compn. of the protein of the young leaves is less stable under this condition, becoming enriched in bases and thus more like that of the full-grown leaves. These effects of the roof-ripening process are attributed to the fact that young leaves contain more of the easily altered reserve proteins, whereas the older leaves contain principally the more stable plasma proteins. The polypeptides of the tobacco leaf sol. in hot water become rapidly poorer in bases during fasting and richer in acid amides. In the early stages of the fasting not only a decompn. of polypeptides takes place but also a synthesis. The formation of melanin N in the hydrolysis of the portion of tobacco insol. in hot water diminishes in the course of the fast whereas this increases in the aq. ext The non-protein N components increase during the fast, just as the concn. of free N compds. increases at the cost of combined N substances, although the increase in free amino acids is less than expected. A part of the amino acids are bases liberated from the polypeptides changes to NH_3, but no direct proportionality between the two processes exists because of the fact that some of the NH_3 is used in the synthesis of amides, and to a certain extent also of bases. At the beginning the synthesis of acid amide in young leaves is very energetic but diminishes in the course of the fast when there is a great accumulation of NH_3. The accumulation of NH_3 is generally more pronounced in the old tobacco leaves. In old leaves the nicotine content diminishes at the beginning of fasting but in young leaves there is at first a slight increase in the nicotine content followed, however, later by a destruction. In the ppt. obtained by Barnstein's method for protein detn. the N is 91–96% of the N insol. in the hot water, the rest consisting of the polypeptides which do pass into the aq. ext. It is also stated that the nicotine-N is not pptd. by $Cu(OH)_2$. S. MORGULIS

Growth of Aspergillus niger and the copper content of the nutritive medium. L. K. WOLFF AND A. EMMERIE. *Biochem. Z.* **228,** 443–50; *Nederland. Tydschr. Hyg. Microbiol. and Serol.* **5,** 66–75(1930).—Cu is necessary both for growth and sporulation of *Aspergillus niger*, the former requiring a min. of 0.2 γ (0.001 mg), the latter of 0.3 γ per 250 cc. of the nutritive fluid For the formation of the black spores as much as 1 γ per 10 cc. is required; they appear quickest in media contg. 1 γ Cu per cc. The *Aspergillus* grown on media deficient in Cu shows no degenerative changes. S. M.

Comparative studies on the action of light and increasing temperature on the carbon dioxide assimilation at different illuminations. KARL NEYDEL. *Biochem. Z.* **228,** 451–86(1930).—The photosynthetic activity of *Cladophora* shows periods of depression during the exposure to direct sunlight at a sharp angle, but not to the same degree as in the case of *Trichomanes*. The depression seems to vary according to the physiol. condition of the cells and with the same illumination it may be as low as 19 or as high as 52%. Corresponding to the much smaller photic inactivation observed in *Cladophora* no morphological or physiol. evidence is found in the cells of the "sunstroke," and unlike that in *Trichomanes* causes neither destruction of chlorophyll nor colloidal alterations in the chloroplasts and cytoplasm. The inactivation process is always reversible. With a const. and not vigorous illumination by means of elec. lamps an intensity can be selected at which both types of algae will continue assimilating for hrs. at a practically const. and similar rate. A rise in temp. from 13° to 23° causes a lowering of about 60% in the assimilation in weak illumination, and of 4% with an illumination of 2.5 times that intensity, and an actual increase of 16% when the illumination intensity is 6-fold. But a rise in temp. from 23° to 33° has a depressing influence at all intensities. Furthermore, while the photosynthetic effect in *Cladophora* is attained chiefly by an increase in intensity of the light, this is accomplished

in *Trichomanes* by an increase in temp. The ecological significance of these facts is elaborated. S. MORGULIS

Absolute viscosity by means of the Brownian movement. II. Viscosity determination of the cell sap of epidermal cells of Allium cepa and of ameba protoplasm. J. PEKAREK. *Protoplasma* **11**, 19–48(1930).—The viscosity of cell sap at 8° and 20–23° is about twice and of endoplasm at 24° about 6 times that of H_2O at the same temp. Vacuole liquid decreases in viscosity with rising temp. in about the same ratio as H_2O. The applicability of the method is demonstrated and its features are discussed. M. H. SOULE

The chemical nature of protein compounds in living cells. OSCAR LOEW. *Protoplasma* **11**, 196–209(1930).—In plant synthesis of protein the labile, active form is first produced. This form is readily coagulated by Et_2O, $CHCl_3$ and CS_2. Dilute NH_3 (1:10,000) causes rapid solidification; NH_2NH_2 (0.2%), NH_2OH (0.5%) and HCN (2%), speedily produce hardening. The mode of protein formation in root and stem is not the same as in ripe seeds. In the stem, reduction of NO_3^- and SO_4^{--} occurs but in the seed N and S are in the form of amino acids. Leaves greatly assist seeds in the production of protein, the process in both being the same, *i. e.*, condensation with introduction of H and S. M. H. SOULE

Salt permeability of the protoplasts. H. WEIXL-HOFMANN. *Protoplasma* **11**, 210–77(1930).—The plasmometric method of Höfler was used to study the action of KCl and $CaCl_2$ on red epidermal cells of *Lamium purpureum*. Freshly cut sections immediately dipped in 0.50 g. mol. KCl were ready for measurement in 2–10 min. In an hr. the absorption was equiv. to 0.02–0.03 g. mol. KCl. Permeability decreased with time, increase in concn. of salt or addn. of Ca^{++}. The results indicate that permeability to alkali salts does not depend on preliminary injury of the cell by the salt. There are some 50 tables of data and 75 references. M. H. SOULE

The feeding power of plants. WALTER THOMAS. *Plant Physiology* **5**, 443–89 (1930).—A crit. review and summary accompanied by a bibliography of 214 papers. WALTER THOMAS

Electric correlation potentials in the leaf of Bryophyllum. E. J. LUND AND M. BUSH. *Plant Physiology* **5**, 491–508(1930); cf. *C. A.* **19**, 3512; **23**, 429.—In the leaf of *Bryophyllum* there exists a complex but characteristic system of continuous elec. currents of variable magnitude. The elec. energy of these currents is continuously dissipated and supplied from sp. types of biochemical processes, probably cell oxidation (*C. A.* **23**, 429). The distal part of the petiole is positive to growing points and to selected points on the lamina of the leaf; but all growing points are not positive to any point on the lamina A point on the lamina close to a growing point may be positive to another growing point. The total e. m. f. in a transverse strip from the leaf and having a growing point at each end of the strip is equal to the algebraic sum of a complex system of e. m. fs. of individual cells of the strip. It is suggested that the phloem is a specialized tissue producing these continuous bioelectric currents assocd. with growth processes. The paper is illustrated with 3 plates including a drawing of the app. used. WALTER THOMAS

Respiration of apple twigs in relation to winter hardiness. W. A. DE LONG, J. H. BEAUMONT AND J. J. WILLAMAN. *Plant Physiology* **5**, 509–34(1930).—The app. used was that previously described (*C. A.* **22**, 4583) but with the substitution of an oil bath for an air bath. The continuous aspiration method was adopted (*C. A.* **23**, 413). The wound respiration from excised twigs was found to be small and a relatively const. fraction of the total respiration. The rate of CO_2 production as measured at any temp. is conditioned by the previous temp. environment of the twigs. If the previous temp. has been higher, a const. level of CO_2 emission is gradually obtained. If the previous temp. has been lower, there is a peak of CO_2 evolution for several hrs., after which a level is gradually attained. The lower the previous temp., the higher is the peak amt. of CO_2. Evidence has been obtained that this temporary excess of CO_2 represents that which was produced during the previous period but which remained dissolved in the twig sap, and which diffuses out of the twigs at the higher temps. because it then becomes less sol. (cf. following abstr.). Hardier varieties of apples show a lower peak of CO_2 evolution than do the more tender varieties. The order of increasing tenderness among 11 varieties coincides almost exactly to that of increasing CO_2 during the peak. Twigs stored at —2°, —6° and —10° for periods up to 30 days with and without aspiration of the surrounding air did not show striking changes in chem. compn. In the measurement of the respiratory rate of any plant tissue the effect of dissolved CO_2 and hence the previous temp. history of the material must be kept in mind. The paper is illustrated with 7 graphs and 8 tables. W. T.

Carbon dioxide dissolved in plant sap and its eff
J. J. WILLAMAN AND WM. R. BROWN. *Plant Physiol.* 413.—The method consists essentially in submerging the twigs in boiling 95% alc. in a closed container and then removing the CO_2 with reduced pressure. The CO_2 is led into standard alkali and titrated (*C. A.* **18**, 2481). The amt. of CO_2 in apple twigs varies with the temp. At 0° it is approx. 150–250 mg. per kg. In plant respiration studies a distinction must be made between the *production* of CO_2 and its *output*. The one may or may not be the same as the other, because of the various factors which affect the amt. of dissolved CO_2. The factors known at present are temp., partial pressure of CO_2 in the atm. around the tissue, and the kind of tissue. The dissolved CO_2 may explain at least 3 phenomena of plant "respiration" measurements, *viz.*: (1) The temporary peak of CO_2 attained when apple twigs are raised from a lower to a higher temp. is probably caused by the lower soly. of the CO_2 at the higher temp. (cf. preceding abstr.). (2) The temporary peak of CO_2 produced when the rate of CO_2 output is measured from plant tissue which has been stored in a closed chamber may be caused by the higher acidity of the sap during the period of accumulation of CO_2 in the closed chamber and partly by the diffusion of the previously formed CO_2 held in soln. because of the higher partial pressure of the CO_2 in the surrounding tissue. (3) Those varieties of apples which possess the greatest winter hardiness show the lowest output of CO_2 and contain the lowest amt. of dissolved CO_2. What the causal connection is between the two is not known at present. A drawing of the app. used and detailed descriptions of the manipulation are given. WALTER THOMAS

Physiological studies on the anthocyanins. L. W. KUILMAN. *Proc. Acad. Sci. Amsterdam* **33**, 876–88(1930).—Anthocyanin in leaves usually does not reduce CO_2 assimilation. The latter, per gram of chlorophyll, was greater in the red leaves than in the green leaves of *Corylus maxima*, *Acer platanoides*, *Malus pumila* and *Chaenomeles japonica*. It was the same in both kinds of leaves of *Paeonea albiflora* and *Berberis neuberti*, and was less in the red leaves of *Fagus sylvatica*. When seedlings of *Fagopyrum esculentum* were exposed to light until they began to redden and then placed in the dark at 5°, 20° and 35° they acquired the most red at the lowest temp. J. J. WILLAMAN

The conception of balance with respect to the absorption of nitrogen, phosphorus and potassium by plants and the influence of the level of nutrition. WALTER THOMAS. *Science* **72**, 425–7(1930).—When only two of the critical fertilizer elements, N, P and K, are applied to a soil the absorption of the third element is depressed on an infertile, but increased on a more fertile soil. T. discusses various explanations of the phenomenon. J. J. WILLAMAN

The lipase of Aspergillus niger. p_H optimum on glycerides of fatty acids. ALEXANDRU IURACEC. *Bull. sect. sci. acad. roumaine* **13**, 103–10(1930).—Acting on triacetin, the p_H optimum for exts. of mycelium was 7.8 for both fresh and dried mycelium, although the latter had the weaker action. *Ibid* 169–76. The optimum p_H is 7.8 on both triacetin and triolein, although the action is weaker on the latter. J. J. W.

The exudation of water from the leaf-tips of Colocasia antiquorum. H. H. DIXON AND G. J. DIXON. *Sci. Proc. Roy. Dublin Soc.* **20**, 7–10(1930).—The exuded water is devoid of solutes, although it is in contact with solns. within the leaf. An *osmometer* is described which imitates this phenomenon and furnishes the probable explanation for it. J. J. WILLAMAN

Acidity changes associated with the keeping quality of apples under various storage conditions (PLAGGE, GERHARDT) **12**. Deguelin. I. Preparation, purification and properties of deguelin, a constituent of certain tropical fish-poisoning plants (CLARK) **10**.

The effect of vitamin deficiency on light sense in cases of xerosis and pigmentation of the conjunctiva. C. H. CHOU. *Natl. Med. J. China* **16**, 365–9(1930).—A study of 31 cases showed that discoloration of the conjunctiva in adults was one of the earliest signs of avitaminosis, similar to the Bitot's spots in children. WM. H. ADOLPH

Ski running at high altitudes after ingestion of phosphorus-containing beverage. A. LOEWY. *Arbeitsphysiol.* 3, 276–86(1930); cf. *C. A.* 23, 5223.—The urines of 25 participants of the Swiss military patrol in a 28- and an 18-km. run on skis were collected after the run and the total nitrogen, NH_3, urea, creatine and creatinine and p_H were determined. The NH_3 N was in all cases under 2% of the total N, the urea nitrogen was over 80% of the total N in 54% of the cases, and from 60 to 80% in 46%. The preformed creatinine N averaged 2.13% of the total N in 80% and in 7 cases the total creatinine N was 2.52% of the total N. The p_H varied between 5.3 and 8.4+; many of the urines were either nearly neutral or alkaline. The results are ascribed to the ingestion of 250 to 300 cc. of a beverage "Eviunis" contg. 0.25 to 0.3 g. P. This beverage was prepd from green plants and contains a phosphorus-vitamin complex in which the P is organically bound in the form of Ca and Mg salts of inositolhexaphosphoric acid. T. M. CARPENTER

Effects of the ingestion of tartrate or sodium aluminum sulfate baking powders on growth, reproduction and kidney structure in the rat. J. F. LYMAN AND ERNEST SCOTT. *Am. J. Hyg.* 12, 271–82(1930).—Dietaries contg. varying amts. up to 2% of a com. alum-type baking powder or up to 4% of a com. tartrate powder were fed to albino rats through several generations. No appreciable effect on rate of growth, av. adult size, reproduction, longevity or kidney structure was noted S. B. FOSTER

The effects of the habitual use of tartrate and aluminum baking powders upon the utilization of food in the rat. RUTH M. KRAFT. *Am. J. Hyg.* 12, 283–7(1930).—Male albino rats were fed a mixed dietary contg. baking powder residues which were prepd by moistening portions of 2 com. powders (cf. preceding abstr.) and heating the moist mixtures to 103° for one hr. Rats were fed from early life to 16 months on diets contg approx. 2% of the alum residue and 4% of the tartrate residue. After 16 months, coeffs. of digestibility were detd. in the conventional manner and when compared with similar data from control animals, there was found to be no appreciable difference in the utilization of food. S. B. FOSTER

Vitamins A and D in fish oils. E. M. NELSON AND JOHN R. MANNING. *Ind. Eng. Chem.* 22, 1361–3(1930).—A number of fish body oils were tested for vitamins A and D. Salmon oil had about one third the vitamin A potency of a good cod-liver oil, while sardine, Alaska herring and tuna oils were one tenth as potent. No vitamin A could be detected in menhaden oil. Tuna and sardine oils were found to be as good as, or better than, cod-liver oil in vitamin D potency. Menhaden, salmon, Alaska herring and Maine herring were found to be much less effective. The com. significance of the data is discussed. S. B. FOSTER

Human-milk studies. VI. Vitamin potency as influenced by supplementing the maternal diet with yeast. SYLVIA S. MCCOSH, ICIE G. MACY AND HELEN A. HUNSCHER *J. Biol. Chem.* 90, 1–13(1931); cf. *C. A.* 22, 2965.—When the maternal diet was supplemented with 10 g. of yeast daily, some substance (other than the antineuritic vitamin since it did not stimulate the appetite) was carried over into the milk which brought about a better utilization of the food consumed by the exptl. animals. In all cases more cals. were consumed during the preëxptl. period than during the exptl. period to produce the same amt. of growth and in some cases less growth. Elaboration of body tissue occurred at a more effective rate on a smaller amt. of food. The vitamin B content of the 3 milks used was inversely proportional to the quantity of milk secreted daily. A. P. LOTHROP

The manganese metabolism of the rat. J. T. SKINNER, W. H. PETERSON AND H. STEENBOCK. *J. Biol. Chem.* 90, 65–80(1931).—The primary object of this investigation was to make a more detailed and coördinated study of the metabolism of Mn than has heretofore been reported. On a stock ration contg. 10.47 mg. of Mn per kg. the total Mn in the rat increased from 0.0015 mg. at birth to 0.0676 mg. at 180 days of age. The concn. was highest at birth, decreased during the 1st 12 days, rose to a 2nd peak at 21 days and decreased thereafter. The chief storage tissues are liver, muscle, bone and hide, the concn. in the liver being the highest. When Mn was added to the ration the amts. in bone, hide, liver and kidney were increased 191, 79, 29 and 29%, resp. Adult rats excreted 80% of the Mn in the feces on the stock ration but this proportion was increased to 99% on adding 5 mg. to the ration daily. On a whole milk diet young rats retained approx. 60% of the Mn ingested over a period of 7 weeks; on a diet of milk plus Mn they contained 3 times as much although weighing only 1/3 more than those on milk alone. The retention of Mn was decreased when Cu and Fe, either singly or together, were added to the diet. If the mother is subjected to a high intake of Mn during the gestation period, the Mn content of the rat at birth can be raised 40% but these mothers, after rearing several litters, are unable properly to nourish their young.

storage of Mn was slow when the young received only mother's milk and the storage was not increased by addn. of Mn to the mother's ration. Bibliography of 20 references.
A. P. LOTHROP

The effects of vitamin deficiency upon the coefficients of digestibility of protein, fat and carbohydrate. R. REDER ST. JULIAN AND VICTOR G. HELLER. *J. Biol. Chem.* **90**, 101–10(1931).—The metabolism of animals on a diet deficient in a given vitamin has been compared with that of animals on the same diet supplemented with the missing vitamin. With vitamins, A, B_1, B_2, C and D, the coeffs. of digestibility of protein, fat and carbohydrate were the same with or without the vitamin. It appears unlikely, therefore, that the digestive process is affected by the vitamins studied. A. P. L.

The nature of the highly unsaturated fatty acids stored in the lard from pigs fed on menhaden oil. J. B. BROWN. *J. Biol. Chem.* **90**, 133–9(1931); cf. *C. A.* **24**, 5057.—A mobilization of highly unsatd. acids occurs in pigs fed a diet contg. about 14% of menhaden oil. There was a storage of 2.7% of highly unsatd. acids in the lard which were of about the same mol. wt. and of lower I no. than the mixt. of acids isolated from the original oil. The pig apparently burns the more highly unsatd. acids from the oil, depositing the remainder while the rat stores acids which are more unsatd. than those of the original oil. A. P. LOTHROP

The ineffectiveness of manganese in nutritional anemia. W. E. KRAUSS. *J. Biol. Chem.* **90**, 267–77(1931).—Mn, when added alone (0.1 mg.) or in combination with Fe (0.5 mg.), did not bring about improvement in rats suffering from nutritional anemia induced by an exclusive liquid whole milk diet. The conflicting results obtained by other workers (cf. Titus, Cave and Hughes, *C. A.* **23**, 1160) are probably not due to impurities in the salts used but to slight differences in the technic of housing and feeding the exptl animals; contamination may occur, the cause of which is not always detectable. Glass equipment throughout should always be used. Results obtained with Cu under most adverse circumstances again emphasize the role played by this element as a specific factor for hemoglobin regeneration in nutritional anemia. A. P. L.

Further evidence of the complex nature of vitamin B. II. Evidence that a third factor exists. CHARLES H. HUNT AND WILLARD WILDER. *J. Biol. Chem.* **90**, 279–91 (1931); cf. *C. A.* **24**, 4081.—A 3rd factor exists in the vitamin B complex of yeast which is distinct from the antineuritic and antipellagric factors. The antineuritic factor (vitamin B) is heat labile in an alk. and acid medium, the antipellagric factor (vitamin G) is thermostable under all conditions tried; the 3rd factor is thermolabile in an alk. medium (p_H 9) when autoclaved for 5 hrs. at 15 lb. All 3 factors are necessary for the growth and well being of the rat. A. P. LOTHROP

A new factor in nutrition. A. BAKKE, MLLE. V. ASCHEHOUG AND CHR. ZBINDEN. *Compt. rend.* **191**, 1157–9(1930).—A concd. ext. of vitamin B fed with a B free basal diet caused the coats of black rats to become silver gray. These animals differed in coat coloring from the whitish gray shown by anemic animals. The silver-gray coat coloring was not accompanied by anemia. The animals developed eye symptoms resembling xerophthalmia although their ration contained vitamin A. The animals were either sterile or gave birth to poor young incapable of living. Since the original B concn. was obtained from wheat germ, the authors extd. wheat germ oil. It failed to produce the peculiar coat coloring nor did it show the toxic properties claimed by other workers. In a new exptl. series one group of rats was fed whole wheat and another wheat germ. The black coats assumed the characteristic gray change upon the germ but not on the whole-wheat diet. If the germ diet was continued the coat coloring changed to normal. The authors infer that wheat germ contains a toxic element which is neutralized by feeding the whole grain. They also assume a development of immunity to the toxicity after long feeding of wheat germ when the coat color becomes normal again. C. M. MCCAY

The distribution of vitamin B and its components in the peanut. F. W. SHERWOOD AND J. O. HALVERSON. *J. Elisha Mitchell Sci. Soc.* **46**, 14(1930). -Whole raw peanuts are fairly rich in vitamin B and contain less vitamin G. The red skins of the peanuts contain more vitamins than the nut meats proper. A. L. MEHRING

Defective diet. Notes on the feeding of tubers with special reference to the question of toxic effects. E. A. SEAGAR. *Trop. Agr.* (Trinidad) **7**, 120–2(1930).—Expts. are described in which rats were fed various carbohydrate storage tubers to det. their nutritive value. The results were similar for the different varieties except that tannia and dasheen sustained life as the sole food for longer periods than yam, sweet potato or Irish potato. Death ensued much quicker with each kind of tuber when it was fed raw. In every case death appeared to be due to deficiency of protein and vitamin A

rather than to the presence of any toxic substance, although the greater nutritive value after cooking might be due to the destruction of a toxic substance upon boiling.
A. L. MEHRING

The nitrogen metabolism of the suckling calf on a milk diet. S. J. ERLER AND K. J. PAVLOVSKII. *Biochem. Z.* **228**, 89–100(1930).—The daily N elimination undergoes small oscillations from day to day. The urine is alk. The urea N constitutes a smaller % of the total N than in the full-grown animal of the species. The calf urine is apparently free from uric acid, but always contains creatine. It contains considerable amts. of hippuric acid. On a milk diet no NH_3 is excreted through the urine. The creatinine coeff. of the calf is 20.3.
S. MORGULIS

Influence of salted yeast on the growth of young rats. L. ROSENOW AND MAX ROSENOW. *Biochem. Z.* **228**, 163–4(1930).—Food yeast can be very effectively preserved by salting, such yeast assuming the odor and taste of cheese. Addn. of such salted yeast to bread causes an increase of 36–60% in growth of young rats in 24 days.
S. MORGULIS

Nutrition and the effect of thyroid. I. Effect of casein in hyperthyroid metabolism. I. ABELIN. *Biochem. Z.* **228**, 165–88(1930).—The hormones undergo continuous catabolism and anabolism just as protein, fat and carbohydrate. The hormone metabolism is associated principally with those particular processes which the hormone stimulates. So in the case of insulin it is the sugar metabolism, of parathyroid the Ca metabolism and of the thyroid the energy metabolism. The more thyroid hormone is available for the body cells the more hormone undergoes catabolism and the more must the energy metabolism increase. The great increase of basal metabolism during hyperthyroidism is regarded as an effort of the organism to destroy and remove the hormone. Some glandular organs, particularly the liver, act as protectors against the flooding of the organism with the thyroid hormone. At first, on feeding thyroid, the liver can destroy and eliminate through the bile considerable quantities of hormone, and the initial effect on metabolism depends probably largely on the increased liver activity. Later, however, the protective action of the liver begins to fail, also its power to store glycogen and fat, or to effect the creatine-creatinine transformation, and thus more of the thyroid hormone must be released into the circulation. The excess amts. of the hormone are used up by the muscles, heart, respiratory organs, digestive tract, etc., which likewise suffer injury manifesting itself in the loss of reserves and an inability of restoration. The nervous system is also an important place where the thyroid hormone exerts its action but little is yet known about this. As soon, however, as it is possible to strengthen the liver in its hard struggle with the hormone excess and to maintain its physiological activity (glycogen storage) the rise in basal metabolism and the general body injury become noticeably slower and less pronounced, and the best means to achieve this is dietary. Only such foods must be employed as will spare and invigorate the liver as well as stimulate the anabolic processes in the cells. A rich supply of casein is shown to exert a very favorable action in this respect. Mild exptl. hyperthyroidism is greatly activated whereas severe hyperthyroidism is thus successfully combated. The liver of rats fed thyroid and casein does not lose so quickly its ability to accumulate glycogen. **II. Effect of vitamins on the course of experimental hyperthyroidism.** I. ABELIN, M. KNUCHEL AND W. SPICHTIN. *Ibid* 189–210.—The hyperthyroid condition is characterized by an abnormal rise in energy metabolism and by the considerable deficiency in anabolic processes. The latter effect can be successfully overcome by nutritional measures for which the vitamins are very essential. The vitamin requirement of the organism affected by hyperthyroidism is increased because the thyroid intoxication causes a diminution in the vitamin content of the organism. By feeding of vitamin-rich products (cod-liver oil, egg yolk, beer yeast, tomatoes, carrots, spinach, etc.) it is possible to reduce or even to check the damage done to the carbohydrate metabolism in exptl. hyperthyroidism. Feeding of bone marrow rich in fat, lipoids and vitamin A was particularly effective, even when in conjunction with very large amts. of thyroid gland the glycogenetic function of the liver did not suffer. Bone marrow promoted the new formation of glycogen and its fixation in the muscles, where a considerable excess of glycogen is found in spite of the thyroid feeding. **III. Influence of definite food mixtures on the hyperthyroid metabolic disturbances.** I. ABELIN. *Ibid* 211–32.—The assumption of a general injurious effect especially of animal proteins on the progress of hyperthyroidism is not sustained experimentally. With a suitable diet contg. 30–40% casein manifestations of hyperthyroidism could be averted. Even after 33–35 days of thyroid feeding the rise in basal metabolism was relatively small, the liver and muscles deposited normal amts. of glycogen and the symptoms of intoxication were either mild or missing entirely. Meat protein exerts an unfavorable

influence on the course of hyperthyroidism. A certain amt. of fat may also counteract the thyrotoxic effect on the liver. In special expts. with variable quantities of fat in the diet, the best results were obtained with a 15% fat mixt. However, a rich vitamin supply is very essential as the same dietary components are much less effective when cod-liver oil, egg yolk and yeast are omitted. The value of a lactovegetarian diet in the hyperthyroidized organism is questioned. S. MORGULIS

Thyroxine and thyroid. I. ABELIN. *Biochem. Z.* **228**, 233–49(1930).—The thyroid gland proteins release certain protective reactions of the organism not obtained with thyroxine, which may be also detd. by the carbohydrate metabolism of the liver. This can be shown by feeding rats 8–10 days with the dry gland or thyroxine. On repeating this 2–3 months later, it is found that the animals tolerate much better small or medium doses of the thyroid proteins than they did previously. Also, whereas during the first feeding storage of glycogen in the liver is inhibited, frequently considerable accumulation occurs during the second feeding. With thyroxine, on the contrary, in both the first and the subsequent expt. the liver is unable to convert the sugar to and store it as glycogen. Likewise, during the second treatment with thyroxine the basal metabolism is increased more readily and to a greater extent. S. MORGULIS

The metabolism of tricaprylin and trilaurin. MAUDE POWELL. *J. Biol. Chem.* **89**, 547–52(1930); cf. Eckstein, *C. A.* **24**, 401.—The depot fat of rats on a diet contg. 25% of trilaurin yielded 25.2% lauric acid; with tricaprylin, however, only a trace of caprylic acid could be obtained. In both cases the I no. of the depot fat is lowered; with trilaurin the sapon. no. is raised from 199 (normal) to 218, but with tricaprylin it is unaffected. K. V. THIMANN

Observations on the serum calcium, proteins and inorganic phosphorus in experimental vitamin B deficiency and inanition. VICTOR SCHELLING. *J. Biol. Chem.* **89**, 575–80(1930).—Dogs deprived of the vitamin-B group showed no significant decrease in serum Ca and no appreciable change in serum proteins or inorg. P in 15 weeks. In dogs fasting after 3 weeks on vitamin-B-free diet, the serum Ca decreased considerably and the inorg. P increased slightly, but only after the body wt. had fallen below 80%. Discrepancies in previous work on blood Ca in avitaminosis B (Ungar, *C. A.* **21**, 2019, Smith, *C. A.* **21**, 2502) are attributed to divergent diet conditions. K. V. T.

A comparison of the influence of iodized milk and of potassium iodide administered directly on the size and iodine content of the thyroid gland of rats. W. E. KRAUSS AND C. F. MONROE. *J. Biol. Chem.* **89**, 581–8(1930).—The feeding of iodized milk, or normal milk to which small quantities of KI have been added, results in a reduction in the size of the thyroid gland of rats, and an increase in the I content of the gland when compared to rats on normal milk. On the high-Ca low-P diet of Steenbock and Black (*C. A.* **19**, 2090), with or without irradiation, the wt. of the thyroid gland was double the normal. The iodization of the general milk supply is suggested. K. V. T.

A study of the antimony trichloride color reaction for vitamin A. IV. The source of vitamin B complex in the biological assay of vitamin A and the stability of vitamin A and of the chromogenic substance in various diluting oils. EARL R. NORRIS AND ANNA E. CHURCH. *J. Biol. Chem.* **89**, 589–98(1930); cf. *C. A.* **25**, 537.—Flattening of the growth curve of rats on diets rich in vitamin A previously attributed to the toxicity of the vitamin A-contg. oil can be prevented by addn. of sufficient vitamin B to the diet. The use of peanut, olive, or coconut oils as solvent causes considerable deviation from the linear relationship between diln. and intensity of $SbCl_3$ color reaction. The chromogenic substance is slowly destroyed in the first 2 oils, but the destruction is prevented by addn. of 0.05% hydroquinone. K. V. THIMANN

The source of excess calcium in hypercalcemia induced by irradiated ergosterol. JAMES H. JONES, MILTON RAPOPORT AND HORACE L. HODES. *J. Biol. Chem.* **89**, 647–56(1930).—The conclusion of Hess, Weinstock and Rivkin (*C. A.* **24**, 3537, 5805), that the excess Ca of the hypercalcemia produced by irradiated ergosterol is not derived from the food, is based on expts. in which the diet Ca was small but sufficient. Dogs on a wholly Ca-free diet, contg. 0.1 cc. irradiated ergosterol soln. of 1500 D per kg. body wt. per day, show no marked rise in serum Ca in 3 weeks, while controls on a Ca-contg. diet developed marked hypercalcemia in 2 weeks. The source of the excess Ca is therefore the food and not the body tissues. K. V. THIMANN

Some observations on the behavior of vitamin A in or from primary sources. E. J. QUINN, J. G. HARTLEY AND M. A. DEROW. *J. Biol. Chem.* **89**, 657–63(1930); cf. *C. A.* 22, 3912.—**Dry spinach lost 70% of its vitamin-A content on storing 15 months in diffused light. The addn. of rancid butter fat over the same period slightly increased the vitamin destruction. Exposure of the petr. ether ext. of carrots to ultra-violet light for 3-5 hrs. completely destroyed the vitamin-A content, and at the same time decolorized**

the ext. The vitamin A of dried tomato, carrot and broccoli is readily extd. by peanut oil. K. V. THIMANN

Bile salt metabolism. V. Casein, egg albumin, egg yolk, blood and meat proteins as diet factors. H. P. SMITH AND G. H. WHIPPLE. *J. Biol. Chem.* **89**, 689–704(1930); cf. *C. A.* **23**, 1161.—Previous detns. of the efficiency of various substances for production of bile salt in the bile-fistula dog are continued. The standard salmon-bread diet yields a const. value of about 100 mg. taurocholic acid per 24 hrs. per kg. body wt. Liver, kidney and beef muscle produce 200–300 mg. per 24 hrs. per kg., casein 125–190, but ovalbumin only 50. Since the endogenous output in fasting or sugar-feeding averages 30–40 mg. per kg. the effect of ovalbumin is very small. Whole beef blood considerably increases the output; red blood cells alone, however, decrease it. Sweet breads give the same output as the standard diet. Tryptic digestion of beef reduces its potency to the level of the standard diet, possibly because of destruction of some amino acids. **VI. Proline, tryptophan and glycine in diet.** G. H. WHIPPLE AND H. P. SMITH. *Ibid* 705–17.—Proline added to the salmon-bread diet increases the taurocholic acid output by 50%; added to an ovalbumin diet it increases it 100%. Tryptophan does not increase the output on an ovalbumin diet, but on a gelatin diet increases it 150%. Glycine also increases the output on an ovalbumin diet. Proline and tryptophan have a cholagog effect; glycine has not. **VII. Indene, hydrindene and isatin.** *Ibid* 719–25.—Indene and hydrindenedicarboxylic acid are without effect on the taurocholic acid output, although from the indene-ring formula of cholic acid an effect would be expected. Isatin increases the output very slightly. Both indene and isatin are powerful cholagogs. **VIII. Liver injury and liver stimulation.** *Ibid* 727–38.—Mild injury of the liver by chloroform immediately reduces the taurocholic acid output, which, however, returns to normal in a few days. Liver fractions active in pernicious and secondary anemia, ferric citrate and apricots are all inactive in increasing the output on the standard salmon-bread diet. Daily refeeding of all bile secreted increases the bile salt output to a high level, but the surplus bile, although it slowly decreases, is not excreted in the urine, as shown by Schmidt and Merrill's method (*C. A.* **18**, 698). **IX. Eck fistula modifies bile salt output.** H. P. SMITH AND G. H. WHIPPLE. *Ibid* 739–51.—The bile salt output of dogs with both Eck and bile fistulas (Smith and Jones, *C. A.* **24**, 5323) is unaffected by liver, Fe salts, or ovalbumin with or without glycine, is reduced by a tryptic digest of meat, and considerably reduced by inhalation of $CHCl_3$. Bile refeeding does not increase the output to such a high level as in the normal dog. Sensitivity to cholagog action is also reduced. The output of bile salt on the standard salmon-bread diet is in many cases lower than in the normal dog. K. V. THIMANN

Studies on the creatine and nitrogen content of the whole rat after the feeding of a variety of diets and after nephrectomy. ALFRED CHANUTIN. *J. Biol. Chem.* **89**, 765–74(1930); cf. *C. A.* **24**, 889.—Creatine analyses of the fat-, ash-, and moisture-free carcass tissue of large nos. of rats on diets rich in casein, edestin, gelatin and dried extd. beef, as well as on protein-free diets, show no appreciable variation. The creatine and N concn. are unchanged 48 hrs. after nephrectomy, indicating that the excess creatine is destroyed or utilized. Rats fed on high-protein diet throughout their entire life show the same creatine content as normal animals. A 10% creatine diet produces apparent creatine "satn." after the first day. Formation of tissue creatine from exogenous sources, as suggested by Mitchell, Nevens and Kendall (*C. A.* **16**, 2713) and others, is considered to be improbable. K. V. THIMANN

Cerebellar disorder in chicks, apparently of nutritional origin. ALWIN M. PAPPENHEIMER AND MARIANNE GOETTSCH. *J. Exptl. Med.* **53**, 11–26(1931).—Growing chicks maintained on a diet consisting of milk powder, casein, starch, yeast, cod-liver oil, salts and filter paper develop ataxia, tremors, retraction or twisting of the head, clonic spasms of the legs and stupor. These symptoms may appear suddenly, usually between the 18th and the 25th day and may end in death. If recovery takes place, the chicks may go on to normal development. This may be a true nutritional deficiency disease, although the nature of the relationship is, however, by no means clear. C. J. WEST

Physiological action of xanthophyll. P. KARRER, H. VON EULER AND M. RYDBOM. *Helv. Chim. Acta* **13**, 1059–62(1930).—Chickens, as well as rats (cf. *C. A.* **23**, 3254), show no growth when fed xanthophyll (0.03 mg. per day). All chickens died in 3–5 weeks. Xanthophyll stearate likewise does not promote growth. A. W.

Relationship of carotene content to vitamin-A activity in various plant substances. H. V. EULER, V. DEMOLE, P. KARRER AND O. WALKER. *Helv. Chim. Acta* **13**, 1078–83(1930).—The carotene and xanthophyll contents of the unsaponifiable portion of the ether ext. from the dry leaves of spinach, beech, *Lolium pirenne* mixed with other

grasses, lettuce and nettles and from the flowers of the marsh marigold and kernels of corn were found to vary from 1.9 to 22.8 mg. and 2.3 to 41.2 mg. per g., resp. The vitamin-A activity of the unsaponifiable matter was found to run parallel to the carotene content. Lycopin, physalin and phaeophytin showed no vitamin-A activity. Dried grass showed an activity equal to about 60% that of fresh grass. A. WIEBEN

H transition in cholesterol (SCHÖNHEIMER) 10.

E. K. MARSHALL, JR.

Recent advances in the physiology of digestion. III. The ruminant stomach. H. H. DUKES. *J. Am. Vet. Med. Assoc.* **31**, 92–7(1931).—A review of mech. and chem. factors in the rumen, reticulum, omasum and abomasum. RACHEL BROWN

Various modes of sugar breakdown in the animal organism. ERWIN BUMM AND KARL FEHRENBACH. *Z. physiol. Chem.* **193**, 238–50(1930).—Animal tissues may be grouped into 2 classes according to their mode of carbohydrate utilization: striated muscle, which prefers glycogen and is able to split hexosephosphoric acids, and tumor, cerebral cortex, spleen and embryonic tissue, which are more active toward glucose. The thermolabile coenzyme T, which functions in the anaerobic utilization of glucose, is especially abundant in tumors. Addn. of T to brain cortex or to kidney tissue doubles the extent of glucolysis. In such tissues the quantity of coenzyme present is the limiting factor in lactic acid formation. The thermostable cozymase of yeast, on the other hand, activates glucolysis by an intermediary formation of hexosephosphoric acid. Striated muscle of rabbit, chicken or rat causes a vigorous breakdown of glycogen, but does not attack glucose unless cozymase is added. Coenzyme T has no effect here; hence the 2 activators are not identical. With white muscle the response is quite different. Both glycogen and glucose undergo glucolysis without addn. of activator; coenzyme T increases the glucolysis of sugar but not that of polysaccharide, while cozymase acts in the reverse manner. To det. whether the cleavage of glycogen and that of sugar are 2 independent processes, or whether they proceed by way of common intermediates, the activation by cozymase and that by coenzyme T were measured separately and then compared with the glucolysis of a system contg. all 4 components. The total glucolysis was equal to the sum of the 2 sep. glucolyses. The processes of glycogen and sugar breakdown are, therefore, independent. If both cleavages lead through the same intermediates the presence of both coenzymes should yield the max. performance. In contrast to white muscle, kidney tissue is activated by both coenzymes, each of which increases the glucolysis 2–3 times. Both glucolytic processes are in operation here, one via hexosephosphoric acid and activated by cozymase, the other independent of cozymase and activated by coenzyme T. A. W. DOX

New internal secretion of the pancreas, the circulatory hormone calicrin and its application. E. K. FREY. *Pharm. Monatsh.* **11**, 271(1930).—An address. W. O. E.

Recent results in hormone investigation with pharmaceutical products related thereto. HANS KAISER. *Süddeutsche Apoth.-Ztg.* **71**, 19–21, 29–31(1931).—An address. W. O. E.

The cycle of iron in the organism. E. STARKENSTEIN. *Naturwissenschaften* **18**, 875–9(1930).—A review of recent work on the role of Fe in the organism (cf. *C. A.* **21**, 1494; **22**, 1407; *Klin. Wochschr.* **7**, 267 (1928); *Z. exptl. Med.* 68 (1929); *Erg. Med.* 14, 565 (1930); S. and Weden, *C. A.* **23**, 208, 890; **24**, 4081). B. J. C. V. D. H.

The chemistry of muscle contraction. J. K. PARNAS. *Naturwissenschaften* **18**, 916(1930).—Expts. on frog muscles poisoned by iodoacetic acid were made to study their NH_3 formation. Isolated poisoned rigid muscle (rigidity caused either by irritation or by prolonged rest) has an NH_3 nitrogen content of 7 to 10 mg. %. However, contrary to the opinion of Embden (*C. A.* **24**, 5352), who attributed this to a lack of reversibility of the NH_3 formation in the poisoned muscle, evidence is advanced that the NH_3 accumulation follows the contractions and is only indirectly caused by them. Immediately after 120 faint contractions (2 per sec.) the NH_3 found is equal to that of normal muscle (1.2 to 1.9 mg. %); one hr. later the content is 7 mg. %, whereas a non-irritated poisoned muscle has only 1.9 mg. % after the same period. Processes caused by the contractions bring about the subsequent NH_3 formation simultaneously with the ultimate rigid condition. In rest condition at 14° the poisoned muscle has after 3 hrs. little NH_3; after another 3 hrs. it has 8 to 9 mg. % NH_3. At the same time it has become stiff. The NH_3 formation in poisoned muscle is irreversible.

Muscle contraction, chemical contraction and lethal rigidity. EDGAR WÖHLISCH. *Naturwissenschaften* **18**, 931–4(1930).—A review of W.'s work and discussion of the problem of the nature of lactic acid action in the muscle (*C. A.* **22**, 3699). Many references are given. B. J. C. VAN DER HOEVEN

The composition, specific gravity and p_H of colostrum. B. VAN DER BURG. *Nederland. Tijdschr. Hyg., Microbiol., and Serol.* **5**, 56–65(1930).—The following detns. were made on a large no. of samples of colostrum and the results extensively tabulated: protein (N × 7.0), fat, lactose, ash, dry substance, Cl, d_{16}^{15}, and p_H. The following averages were found: protein 17% (max. 26.6, min. 6.6), fat 3.3% (max. 12.0, min. 0.5), lactose 2.5%, (max. 3.9, min. 0.5), ash (sulfate ash) 1.04% (max. 1.61, min. 0.70), Cl 165.5 mg. per 100 g. (max. 460.5, min. 53.8), dry substance 23.8% (max. 38.2, min. 13.6), sp. gr. 1.0652 (max. 1.0936, min. 1.0366), p_H 6.22 (max. 6.88, min. 5.95). J. C. J.

Biochemical studies on skin, bone and shell. I. Sexual differences in the composition of bone. HIROMICHI HARA. *J. Agr. Chem. Soc. Japan* **6**, 655–8(1930); *Bull. Agr. Chem. Soc. Japan* **6**, 35–6.—The bones of rabbit, pig and mackerel were investigated. Ca was generally higher in the female, and P higher in the male. When these data were calcd. on the basis of N = 100, the contents of both Ca and P were higher in the female. Y. KIHARA

The elimination of uric acid after intravenous injection. GINO BERGAMI. *Biochim. terap. sper.* **17**, 310–22(1930); cf. *C. A.* **24**, 1897.—A soln. of 1 g. uric acid, 0.28 g. Li_2CO_3 and 1.35 g glucose in 100 cc. H_2O was intravenously injected into dogs and rabbits and the elimination detd. The uric acid disappears rapidly from the blood. The increase in non-protein N is continued after the uric acid disappears. The latter is fixed in the kidneys, which become edematous; it disappears from the kidneys within some hrs. During the following days, the elimination of uric acid, allantoin, urea and NH_3 in the urine is increased, but not in proportion to the uric acid injected. A certain part of it is eliminated in an unknown way. A. E. MEYER

Metabolism during stimulation and response of the nerve. O. MEYERHOF AND W. SCHULZ. *Biochem. Z.* **228**, 1–5(1930).—The increased oxidation results from the general response of the whole nerve and not from the locality of the irritation. This holds only for the peripheral nerves. S. MORGULIS

The biochemistry of carbohydrate metabolism in washed muscle tissue. A. UTEVSKII. *Biochem. Z.* **228**, 135–45(1930).—The formation of acetaldehyde transformation products of pyruvic, fumaric and malic acids was followed in normal and in washed muscles, also in washed muscle and boiled juice. In washed muscle tissue undergoing autolysis aldehyde is produced in very minute amts. or practically not at all, and this is not altered by the addn. of glycogen, glucose, fructose or glycerol. In the presence of EtOH or of lactates a small amt. accumulates. In the presence of pyruvates acetaldehyde accumulates in the same amt. as in unwashed muscle, showing that the decarboxylase activity is unaffected. The ability to form acetaldehyde by the muscle is restored through the addn. of boiled juice. The transformation of pyruvates by the washed muscle tissue is greatly reduced, indicating that the oxido-reductase is destroyed although the decarboxylase is unaffected. The former, however, is restored by the addn. of boiled juice. The change of fumaric to malic acid proceeds equally well in the washed and unwashed muscle tissue, but the further transformation of malic acid by washed muscle is very much decreased. The addn. of boiled juice corrects this also. It is maintained that the washing does not merely remove substances which are H donors, but that coenzymes necessary for the enzymic processes are lost, and are restored by the addn. of the boiled juice. S. M.

Influence of thyroid gland substances on the total creatinine content of liver and muscles. I. ABELIN AND W. SPICHTIN. *Biochem. Z.* **228**, 250–6(1930).—Feeding rats on thyroid substance causes a great diminution in the total creatinine content of the liver and of the striated muscles. The loss of creatine-creatinine, the almost complete absence of glycogen and strong reduction of the fat depots are all manifestations of the injuries to the hyperthyroid metabolism. S. MORGULIS

Studies on the extra-hepatic bile pigment formation in surviving organs. V. Is there a relation between the bilirubin production of the surviving spleen and the quantity of red cells lodged in the spleen parenchyma? Z. ERNST AND E. HALLAY. *Biochem. Z.* **228**, 354–65(1930).—The dog's spleen perfused with defibrinated blood can produce bile pigments. To test whether this is due to the destruction of the red cells which pass outside the capillaries of the parenchyma and whose hemoglobin is changed to the bile pigments, the quantity of red cells in the spleen parenchyma was greatly increased by raising the arterial pressure and establishing venous stasis at the same time, but

the bile pigment production was not affected. Conclusion: Other factors besides the no. of red cells undergoing destruction must be responsible for the pigment production. Cf. *C. A.* **20**, 1276. S. MORGULIS

The ammonia content and the ammonia production in the frog muscle. VII. J. K. PARNAS, W. LEWINSKI, J. JAWORSKA AND B. UMSCHWEIF. *Biochem. Z.* **228**, 366–400(1930); cf. *C. A.* **23**, 3000.—The frog muscle is quickly rubbed up in a glass mortar in a few cc. of cold satd. borax soln. made previously NH_3-free by boiling. This procedure can be employed only with very small muscles which are at once reduced to a pulp by pressure of the pestle. The NH_3 is detd. by the method of Parnas. It is maintained that the facts do not support the view that the NH_3 formed during muscle contraction disappears in a few seconds after the contraction. This is particularly well shown on the living frog where the NH_3 accumulated during activity disappears very slowly, and is still found even after 30 min. This, of course, also occasions variations in the NH_3 content of the muscles of normal frogs. The NH_3 furthermore escapes from the muscle into its surrounding fluid, and in the *in vitro* expt. can be found in the Ringer soln. and *in vivo* in the venous blood from the muscle, and this may also be erroneously attributed to a resynthesis. S. MORGULIS

Experiments on extracting hormones with the aid of a special vividiffusion method. CARL MÜLLER. *Endokrinologie* **7**, 401–15(1930).—The method depends upon a slow perfusion of the peritoneal cavity with physiol. saline soln., the peritoneum being used as a seat of vividiffusion. The presence of hypophysin and of adrenaline in the perfusate could be demonstrated quantitatively in biol. tests, with the perfusate for intravenous injections. This indicates that both hormones freely circulate in the organism without undergoing rapid destruction. S. MORGULIS

Urinary galactose in men and women after ingestion of galactose. VICTOR J. HARDING AND OLGA MOBERLEY. *J. Biol. Chem.* **89**, 535–45(1930); cf. *C. A.* **24**, 2784.—The urinary excretion of galactose after ingestion varies widely in men and women, being in some cases slightly higher in women. Since the diuretic response of women to the water ingested with the galactose is greater, however, the concns. of galactose in the urine of the women are lower, and are close to the threshold of sensitivity of the qual. Bertrand test. The results of Rowe (*C. A.* **24**, 650, 1668; *Endocrinology* **13**, 263(1929)) which were based on this test appeared to show a greater tolerance to galactose in women than in men. K. V. THIMANN

The recovery process after exercise in the mammal. I. Glycogen resynthesis in the fasting rat. C. N. H. LONG AND RHODA GRANT. *J. Biol. Chem.* **89**, 553–65(1930).—Fasting rats were exercised artificially by electrical stimulation so as to reduce the total body glycogen by const. amts., and the liver, blood and carcass separately analyzed. The blood lactic acid, which reaches 150–200 mg. % immediately after the exercise, is completely reduced to normal in 1 hr.'s recovery, but on the other hand the carcass glycogen is not restored to its normal value for more than 5 hrs. The glycogen content of the liver (cf. Cori and Cori, *C. A.* **22**, 1623, 4590) is not greatly altered during and after exercise, so that if glycogen is resynthesized in the liver from lactic acid, it is not stored there, but probably returned to the blood as glucose. The lactic acid content of the whole body returns to its normal value after 2 hrs.' recovery. The blood sugar is lowered during the exercise but returns to normal after about 1 hr.'s recovery. K. V. THIMANN

Metabolism of amines. II. Dimethylamine. WILSON D. LANGLEY AND RICHARD J. WEBER. *J. Biol. Chem.* **89**, 567–74(1930); cf. *C. A.* **24**, 1148.—From rabbits fed with 92–220 mg. of $NHMe_2$ per kg. body wt., given as hydrochloride with $NaHCO_3$, 1–30% of the amine was recovered in the urine. If 2 equivs. of $NaHCO_3$ were given, the recovery was 29–61%. Only traces of tri- and mono-methylamines were recovered. Most of the N which is metabolized is excreted as urea. K. V. THIMANN

An apparent effect of normal variations in the respiratory rate upon the excretion of chloride and water. ROGER S. HUBBARD AND CATHERINE B. ALLISON. *J. Biol. Chem.* **89**, 627–30(1930); cf. *C. A.* **24**, 407, 4819.—The conditions which tend to produce an alk. urine in achlorhydria patients also tend to increase the excretion of fluid, but the Cl excretion is increased more than would be expected from the vol. increase. The results are similar to those of Simpson and Wells (*C. A.* **22**, 978). K. V. T.

Geographic location and the iodine content of the thyroid gland. F. FENGER, R. H. ANDREW AND J. J. VOLLERTSEN. *J. Am. Chem. Soc.* **53**, 237–9(1931).—Calcd. on the desiccated fat-free basis, the yearly av. for hog thyroid glands from N. Dakota is 0.32% I, while that of Texas glands is 0.60% I. The seasonal variation in the I content is most pronounced in the northern glands. The higher I level of the Texas glands and

the greater seasonal fluctuations of the N. Dakota thyroids are attributed to the geographic location of the 2 states. C. J. WEST

Influence of uric acid on the permeability of membranes. VIRGILIO CHINI. *J. Exptl. Med.* **53**, 1–9(1931).—Congo red (I) injected *in vivo* together with uric acid (II) gives rise to more intense and diffuse red coloring in rats, especially in the subcutaneous and peri-articular tissues, than is the case in control rats injected with dye alone. II added *in vitro* to solns. of I or trypan blue increases the speed of diffusion of these dyes, both through gelatin and the animal membranes (dialyzers). These results support a view long maintained by Rondoni, that some factor of an endothelial-capillary nature must be taken into consideration in manifestations of hyperuricemia and of gout. C. J. WEST

Factors which determine renal weight. XI. Renal function. EATON M. MCKAY AND BURRELL O. RAULSTON. *J. Exptl. Med.* **53**, 109–13(1931).—The amt. of functioning renal tissue as measured by the wt. of the kidneys in the albino rat is directly proportional to the renal function as measured by the ratio: urine urea rate/blood urea concn. under certain special conditions. C. J. WEST

Absorption from the pericardial cavity. CECIL K. DRINKER AND MADELEINE E. FIELD. *J. Exptl. Med.* **53**, 143–50(1931).—Physiol. salt soln. is absorbed from the pericardial cavity of medium-sized rabbits at a rate of approx. 1.3 cc. per hr. This absorption is via the subepicardial blood capillaries. Rabbit and horse serums are absorbed extremely slowly, an indication of the low-grade lymphatic drainage of the pericardial sac. Graphite particles of bacterial dimensions are also removed very slowly. Such particles enter the lymphatics only after phagocytosis. C. J. W.

Ratio of the glomerular and tubular eliminations of the urinary constituents. SAKAE YOSHIDA. *Proc. Imp. Acad.* (Japan) **6**, 381–2(1930).—Chloride is eliminated with H_2O almost exclusively through the glomeruli and reabsorbed partly in the tubules, while other urinary constituents are excreted mainly from the glomeruli and only partly from the tubules. C. J. WEST

Glucose threshold in kidney. SHICHIRO IMAGAWA. *Proc. Imp. Acad.* (Japan) **6**, 383–4(1930).—From a study of phlorhizin, $HgCl_2$ and KCN, it is shown that in the glomerular circulation the drugs cause glucosuria even in very high diln., while in the capillaries around the tubules, it is necessary to establish a much higher concn. (up to 200 times). These exptl. results can be interpreted more readily by accepting the existence of the threshold for blood sugar in the glomerulus. C. J. WEST

BERG, RAGNAR: **Kontrolle des Mineralstoffwechsels.** Leipzig: S. Hirzel. 87 pp. M. 5.

G—PATHOLOGY

H. GIDEON WELLS

A chemical study of sclerema neonatorium. T. T. CHEN. *Nat. Med. J. China* **16**, 360–4(1930).—Subcutaneous fat and fat-free skin of 8 sclerema and 4 non-sclerema babies were analyzed. The fat samples showed no differences in m. p., iodine no. and sapon. no. The Ca and P contents of the tissues also were about the same. WM. H. ADOLPH

The purification of tuberculin. I. ERNST MASCHMANN AND EMIL KÜSTER. *Z. physiol. Chem.* **193**, 215–37(1930).—The protein-free nutrient medium of Sauton (*C. A.* **6**, 2945) is well adapted to the prepn. of an active tuberculin. After 6 or more weeks at 38° the culture is filtered through paper, then through Berkefeld filters, and its potency is detd. by ascertaining the min. dose fatal to tuberculous guinea pigs within 24 hrs. after subcutaneous injection. The soln gives characteristic reactions for proteins and protein decompn. products, and the Molisch reaction for carbohydrates. The presence of proteins and carbohydrates is obviously due to autolysis of dead tubercle bacteria. The specific active substance in tuberculin diffuses readily through animal membrane (so-called fish bladder). Higher mol. proteins may be removed without loss of the sp. substance by acidifying the crude or the partially dialyzed tuberculin to p_H 3.8 with AcOH. After this treatment the sp. substance is adsorbed at p_H 3.8 on kaolin purified by electrodialysis, leaving the carbohydrates in the residual soln. It is then extd. in good yield by elution of the kaolin adsorbate with very dil. NH_4OH. The purity of the sp. substance is now 20 times that of the crude tuberculin. The prepns. all give feeble biuret and ninhydrin, some give Millon, but none the tryptophan or Molisch reactions. The carbohydrate remaining from the kaolin adsorption has the properties of glycogen. A. W. DOX

Copper and tuberculosis. PAULO SEABRA. *Arch. Pharm.* **268**, 565–7(1930).—A

preliminary study shows that tuberculosis decreases the Cu content of the lung. This decrease appears to depend on the extent of the lesion. W. O. E.

A contribution to our knowledge of leak disease, bone hardening and softening with especial reference to the chemical significance. E. RITTER. *Landw. Jahrb. Schweiz* **43**, 491–526(1929).—The disease is prevalent in Switzerland. There has not been a satisfactory explanation of the cause, which R. now assumes is either the proteins and their different biol. activities, the vitamin content or the mineral matter of the food. Phosphate fertilization of soils and the use of molasses, prepd. chalk and other minerals in the food have resulted in a decrease in the disease and improvement in the infected animals. It is believed that building up the soil so that the crops are higher in mineral content will have a beneficial effect. GEORGE R. GREENBANK

Emmanuel and Rosenfeld's mastic test for the cerebrospinal fluid and its significance for the diagnosis of syphilis of the central nervous system. G. EMMANUEL AND H. ROSENFELD. *Med. Klin.* **26**, 553–5(1930); *Bull. Hyg.* **5**, 725.—A mastic soln. in C_2H_5OH and a buffered NaCl soln. of p_H 7.5 are used. Dilns. of the cerebrospinal fluid are made up to 1 to 1024. With normal serum only the first two tubes show a slight turbidity. Grades of reaction are recognized as in the gold sol test. Flocculation in the first two tubes due to excess globulin is characteristic of syphilis. Blood may cause turbidity in the tubes of moderate diln. GEORGE R. GREENBANK

The fading of tropeolin OO in the titration of organic acids in urine. K. LUCILLE MCCLUSKEY. *J. Biol. Chem.* **90**, 197–201(1931).—A substance, probably of endogenous origin, has been found in certain pathol. samples of urine, which causes a fading of tropeolin OO when this indicator is used in the Van Slyke and Palmer method for the detn. of org. acids. It is easily oxidized and can be removed from urine by aeration in the presence of HCl. It may be an unoxidized S compd. arising from the destruction of tissue protein. It occurs in the urine at intervals in 30–40% of persons very ill from tuberculosis but it is probably present in other diseases. A. P. LOTHROP

The decrease of the capillary buffer power in cancerous serum. W. KOPACZEWSKI. *Compt. rend.* **191**, 1155–7(1930).—The surface tensions of sera from 59 normal and 14 cancer (face and tongue) cases were detd. after the addn. of amts. of Na glycocholate varying from 0 to 0.005%. Values for normal sera were 1-3 dynes/cm. higher than those for the cancerous. C. M. MCCAY

Congenital porphyria with polyneuritic symptoms. FERDINANDO MICHELI AND GIORGIO DOMINICI. *Minerva med.* 1930, II, 505–19.—Cases of porphyria in a mother and a daughter are described. The clinical findings are given in minute details. Both patients showed a marked hyperpigmentation of the skin which was greatly accentuated when exposed to the action of sunlight. The nosography is discussed and a classification of the various forms of the disease is given. The syndrome is closely related to metabolic disorders which result in the abnormal production and elimination of porphyrins in the feces and urine and their increase in the blood and duodenal fluid. The nervous phenomena are attributed to degenerative changes in the cells of the anterior horn, of the cells of the spinal ganglia and of the peripheral nervês. Essential for the diagnosis of the disease is the elimination of dark urine, of a port-wine color. The urine shows a red fluorescence and is rich in coproporphyrin and uroporphyrin. The feces, blood serum and duodenal fluid may also show these. A spectroscopic examn. is necessary for the diagnosis. Therapeutic measures are also given and in cases of hypersensitiveness of the skin avoidance of sunlight is a requisite. PETER MASUCCI

Chloremia and chlorine metabolism in various pathological conditions. C. CIPRIANI AND G. C. DOGLIOTTI. *Minerva med.* 1930, II, 549–55.—Systematic studies were made on chloremia and on the metabolism of chlorine in clinical cases of intestinal occlusions. From the results obtained, the assertion is made that the hypochloremia of high intestinal occlusions resembles somewhat the toxic hypochloremia with and without vomiting. The pathogenesis of toxic hypochloremia in intestinal occlusions is attributed not only to an increased elimination of chlorine but also to a disturbance of the equil. of NaCl in the blood, tissues and kidneys. PETER MASUCCI

A substance producing hyperthermy, contained in brewers' yeast. ANTONIO SPINELLI. *Biochim. terap. sper.* **17**, 397–401(1930).—Mix 500 cc. H_2O, 250 g. yeast and 10 cc. 5% NaOH and autolyze during 15 to 25 days at room temp. When 0.7–0.8 cc. of the filtered liquid is injected intravenously into a rabbit, a rise of the temp. to 41.8° during 5 to 6 hrs. is observed. The prepn. is recommended for production of artificial fever in animal expts. A. E. MEYER

The products of protein cleavage in the spinal fluid. GUISEPPE AIELLO. *Biochim. terap. sper.* **17**, 414–8(1930).—The tryptophan reaction is positive in the spinal fluid in tuberculous meningitis, but in few other conditions. The values of N vary between

0.41 and 2.4 in this disease but are not proportional to the gravity of the case or to the intensity of the tryptophan reaction. For the diagnosis, the detn. of the amino acids is of value only in assocn. with the clinical data. A. E. MEYER

Human isoagglutination in serum sickness. GUISEPPE GELLI AND GIANCARLO TAROZZI. *Biochim. terap. sper.* **17**, 419–27(1930).—In cases of diphtheria treated with serum, the titer of the isoagglutinins decreases to normal when the anaphylactic conditions have scarcely passed. A. E. MEYER

The action of some colloidal solutions on diphtheria toxin. G. ROSSI. *Biochim. terap. sper.* **17**, 437–44(1930).—Colloidal S inactivates diphtheria toxin when the two are mixed and injected in guinea pigs. Congo red, HgS and As_2S_3 have no effect. A. E. MEYER

The spinal fluid of the new born. CARLOS M. PINTOS. *Semana méd.* (Buenos Aires) **1930**, II, 1815–20.—In 98% of the babies tested xanthochromia was observed during the first 10 days. For the yellow fluid in 88% of the cases the indirect reaction of van den Bergh was positive. A. E. MEYER

Glucolysis in blood with special reference to lactic acid formation. OTTO JERVELL. *Acta Med. Scand.* **74**, 221–34(1930).—No difference was found in the glucolytic power of bloods under various pathol. conditions, and the glucolysis was practically always the same. A glucolytic enzyme in the serum of cancer patients could not be demonstrated. The increased glucolytic power of cancer tissues is attributed to the relatively high cell content of those tissues rather than to any alteration in general metabolism. The greatest loss of sugar occurred during the first hr., and after 4 hrs. the largest part of it disappeared. With the aid of the Hagedorn-Normann Jensen method the av. residual reduction was 15.4 mg. %. In 18 cases, or 60% of the total, the sugar value after the termination of glucolysis increased; this may be due to a new synthesis. The glucolysis is independent of the initial concn. of the blood sugar, and insulin either given by injection or added directly to the patient's blood has no effect on it. The lactic acid production did not correspond to the sugar deficit, and in 23 cases it accounted for only 58%; it is suggested that the glucolysis results only partly in lactic acid. S. M.

Sugar content of cerebrospinal fluid. II. Studies on the influence of the glucose-adrenaline hyperglucemia on the cerebrospinal fluid in organic diseases. CARL J MUNCH-PETERSEN. *Acta Med. Scand.* **74**, 235–83(1930); cf. *C. A.* **25**, 744.—In the absence of definite endocrine involvement a change in reaction from the normal, *i. e.*, outside the limit 0.015 to 0.030%, may betray a deep-seated affection of the central nervous system. S. MORGULIS

A study of the parathyroid enlargement in osteitis fibrosa generalisata. E. ASK-UPMARK. *Acta Med. Scand.* **74**, 284–323(1930).—The enlargement of the parathyroid gland is considered to be the rule in osteitis fibrosa generalisata, although in some rare cases there was no enlargement present. The parathyroid enlargement is considered primary to the bone disease, the Ca metabolism of the patient being noticeably disturbed. Improvement of the condition in Recklinghausen's disease generally follows parathyroidectomy but the danger of postoperative tetany is present. S. M.

The biology of the meal worm Tenebrio molitor. I. The water content. FR. N. SCHULZ. *Biochem. Z.* **227**, 340–53(1930).—*Tenebrio molitor* is extraordinarily resistant to desiccation. In vacuum-dried bran the full-grown larvae can be kept for months in a dry air current, where they undergo metamorphosis. The growth of the larvae stops, and the non-puppated larvae remain in this stage for months. The metabolic H_2O condenses on the dry bran around the larvae, but since there is complete cessation of growth it is an open question whether this moisture does any good. The adjustment to the extreme conditions of desiccation is through a limitation of the vital processes and the condensation of the metabolic H_2O on the surface. Furthermore, there is production of a wax-like substance which evidently serves to prevent evapn., and, together with the animal's covering of chitin, makes it possible for the meal worms to maintain their water content. The worms consume much smaller quantities of bran under the condition of desiccation. S. MORGULIS

Note on the metabolism of tumors. OTTO WARBURG. *Biochem. Z.* **228**, 257–8 (1930).—Degenerating cells lose their respiratory function sooner than their glucolytic ability, so that they begin to glucolyze aerobically. This is found in the case of cells in the process of dying, but also in asphyxiated embryonic tissues. The latter, whose respiration is irreversibly destroyed, show a metabolism like that of tumors, yet they do not develop into tumors. Transplanted subcutaneously, the asphyxiated embryonic tissues may give rise to teratomas or disintegrate, but they do not become tumors. Only when the injury to the oxidative process is transmitted from cell to cell in the course of cell division can tumors originate. S. MORGULIS

Purification and concentration of diphtheria toxin and anatoxin with special reference to active immunization of man. S. SCHMIDT AND A. HANSEN. *Biochem. Z.* **228**, 263–90(1930).—By a combination of adsorption of toxin and anatoxin by means of Willstätter's $Al(OH)_3$ and charcoal very concd., colorless and odorless prepns. were made which retained the specific immunological properties of the crude toxin and anatoxin. With the described technic of prepn., toxin and anatoxin were obtained with 500–1000 units per cc. with the same protein content, however, as that of the crude prepn. With this anatoxin prepn. it is possible to produce a strong and lasting immunity against diphtheria by a single injection. S. MORGULIS

Purification and concentration of diphtheria toxin and anatoxin by precipitation with acids. S. SCHMIDT AND K. A. KJAER. *Biochem. Z.* **228**, 291–9(1930).—By adjusting the p_H of crude toxin or anatoxin to 3.5–4.1, ppts. are obtained which when sepd. by centrifuging and dissolved in alk. soln. retain 50–60% of the specific activity of the substance but only traces of the non-specific protein. Certain alterations, however, take place under the influence of the acid, since the immunizing action of the purified anatoxin is less than that of the crude anatoxin. S. MORGULIS

Diphtheria toxin-antitoxin precipitate. FERNANDO MODERN AND RAÚL WERNICKE. *Anales asocn. quím. Argentina* **18**, 47–56(1930).—Diphtheria toxin-antitoxin ppt. requires a min. acidity of p_H 3.6 to go into soln. completely. At greater p_H it is incompletely sol. Keeping acid the soln. of the toxin-antitoxin causes dissocn., setting free the antitoxin. Recovery is a max. for media of p_H 3.2–3.6. Recovery depends upon the temp. of the acid soln., the max. being at 10–15°. In the course of time, starting with the instant of soln. of the toxin-antitoxin ppt., dissocn. increases simultaneously with increase in the unit content of the soln. The yield of antitoxin units recovered by dissocn. of the toxin-antitoxin ppt. increases with its diln. in acid soln., and in some cases the ratio of antitoxin units to protein reaches values greater than 18 times that of the original serum. E. M. SYMMES

Tests on purification of antidiphtheria serum by adsorption with aluminum hydroxide. RAÚL WERNICKE AND FERNANDO MODERN. *Anales asocn. quím. Argentina* **18**, 98–111(1930). —Dry, powd. $Al(OH)_3$, added to antidiphtheria serum, adsorbs little or no protein and antitoxin. $Al(OH)_3$ pptd. in the serum adsorbs considerable protein and diphtheria antitoxin when practically neutral media are used. Adsorption is less in alk. media, particularly for the antitoxin, thus permitting concn. of the latter. $Al(OH)_3$ shows no marked selective adsorption for antitoxins in neutral media. Soln. in alk. media of $p_H > 8.4$ gives quant. recovery of the proteins and antitoxins adsorbed by $Al(OH)_3$. E. M. SYMMES

Occurrence of seasonal variations in the goiter of rabbits produced by feeding cabbage. BRUCE WEBSTER, DAVID MARINE AND ANNA CIPRA. *J. Exptl. Med.* **53**, 81–91 (1931).—The evidence presented indicates that cabbage maturing in the spring and summer months has little goiter-producing power. Cabbage maturing in the late summer has much greater goiter-producing power, although this shows considerable variation in different years. It has not been possible to correlate available meteorological data with these variations C. J. WEST

LAROCHE, GUY, RICHET, CHARLES, FILS, AND SAINT-GIRONS, FRANÇOIS: **Alimentary Anaphylaxis (Gastro-Intestinal Food Allergy).** Translated by Mildred P. Rowe and Albert H. Rowe. Berkeley, Calif.: Univ. of Calif. Press. 139 pp. $2, postpaid.

R. A. GORTNER

Spectrographic analysis of animal tissues. H. MUNRO FOX AND HUGH RAMAGE. *Nature* **126**, 682(1930); cf. *C. A.* **23**, 5429.—All of the annelids, molluscs and phylla (146 in all) examd. showed the presence of Fe and Cu. Mn was found in all 19 polychetes examd., in numerous organs of marine gastropods, but was absent from *Haliotis*. Ni and Co (Co usually less than Ni) were present in certain tissues. The foot of *Haliotis* had 0.004% Ni with no Co. The liver of *Archidoris tuberculata* contained 0.003% Co with no Ni. Pb and Ag occur spasmodically. Humans absorb these 2 elements selectively, indicating an absence of functional significance. The highest quantity of Ag was found in the liver and kidney of *Pinna pectinata*. Cd was found in all 11 *Pecten maximus* individuals examd. Li is widespread. Rb is less common. None with Cs was found. Sr was present in 17 of 19 *Polychaetes* and in 51 of 67 tissues of molluscs. Ba was absent. CaF_2 was found only in the body wall of *Archidoris tuberculata*. ARTHUR FLEISCHER

Physicochemical conditions of the habitat of Nereis japonica Izuka. SHICHIROKU NOMURA. *Science Repts. Tôhoku Imp. Univ.* [4], 5, 549–53(1930).—The H_2O of the habitat of *Nereis japonica* Izuka was analyzed. The Cl content varied from 1.75 to 18.35 g. per l. Values found for d_4^{16} on different days were 1.01729 and 1.02430. p_H values were 7.5, 8.3, 8.1. *Nereis*, in general, lives in the sand or mud of the seashore between the tide marks. Changes in the salinity at low tide may not affect *Nereis* to any extent, either because of retention of sea water in the sand or because of protection of *Nereis* by a tube of sand particles cemented together with mucus secreted around the body. These circumstances seem to aid the animal in surviving a wide range of external changes. When the animals were kept in sea water (Cl content 18.30 g. per l.), and tap water or distd. water was added gradually so that the salinity was decreased to about 70% of that of ordinary sea water they became sluggish and did not live as long as in sea water. Their death in this case was probably caused by osmotic relationships. LOUISE KELLY

Chemistry of cell division. I. Effect of glutathione on cell division in Ameba proteus. CARL VOEGTLIN AND H. W. CHALKLEY. *U. S. Pub. Health Repts.* 45, 3041–63(1930).—A method is described for the study of the influence of chem. substances upon the division of *Ameba* under conditions which almost completely eliminate the uncontrollable nutritional factors. With this technic the following results were obtained: (1) The percentage of occurrence of nuclear divisions and cell divisions and the no. of polynuclear cells found at the end of the expts. vary directly with the vol. of cells used. The process of cell division, therefore, depends on the cell vol. (2) The percentage of occurrence of nuclear, and probably of cell, division apparently varies directly with the H-ion concn. over the range covered. (3) Exposure of *Ameba* to SH or S-S glutathione results in more nuclear and cell divisions and more polynucleate cells than in the controls. This is true for nuclear division, and to some extent for cell division, between p_H 6.0 and 8.1. However, the percentage increase in nuclear division in SH glutathione over that in the controls is probably not influenced by the H-ion concn. over the range covered. (4) The percentage increase in nuclear division and cell division and the no. of polynuclear cells in SH glutathione soln., as compared with the controls, vary with the vol. of the cells used, and reach a max. in all 3, when the cells used are about 0.002 to 0.0025 cu. mm. in vol. (5) The effect of SH glutathione is much greater on nuclear division than on cell division in cells having vols. between 0.00125 and 0.0022 cu. mm. This indicates that glutathione exerts a more marked influence on nuclear division than on cell division in cells of this range of vol. (maturity). J. A. KENNEDY

Modifications of the interior of anadromous fish in the course of reproduction. FONTAINE. *Compt. rend.* 191, 736–7(1930).—The osmotic pressure and the chloride content of the blood serum were detd. upon specimens from marine lampreys and *Alosa commune* while they were in excellent health just before spawning. Similar detns. were run during the exhausted period following the spawning season. The debilitation that follows spawning is characterized by the low osmotic pressure and the low Cl content of the serum. C. M. MCCAY

Hormones producing color changes. GOTTFRIED KOLLER AND EVA MEYER *Biol. Zentr.* 50, 759–68(1930).—Substances which produce the change of the color in crawfish are not specific for a single species only when given by injection. Ext. from the eyes of *Crangon vulgaris Praunus inermis* and *flexuosus* produces pigmentation in *Idotea tricuspidata*. Effects on the melanin of certain fishes were also observed. A. E. MEYER

Ammonia formation in the frog heart. I. P. OSTERN. *Biochem. Z.* 228, 401–6 (1930).—The functioning frog heart produces considerable quantities of NH_3 which are apparently proportional to the work performed. The traumatic NH_3 production of the frog heart is much slower than that of the skeletal muscle. S. MORGULIS

Effect of feeding of certain organs of internal secretion from young and old animals on the development of frog tadpoles. G. DESSY. *Endokrinologie* 7, 432–45(1930).—The growth and metamorphosis of tadpoles fed on heart from old cows proceeds much more rapidly than of those fed on heart from young cows, the development of the forelimbs though not of the hind limbs being twice as rapid. The disappearance of the tail was twice as rapid in the tadpoles fed with heart from young as from old animals. The mortality was greater in the tadpoles fed on old hearts. S. MORGULIS

Amytal anesthesia in fishes. A. B. KEYS AND N. A. WELLS. *J. Pharmacol.* 40, 115–28(1930).—Amytal in a 1 or 2% soln. was given intraperitoneally to the salt-water fishes *Girella migricans* and *Clinocottus analis*, and to the fresh water fishes *Apomotis cyanellus* and *Carassius auratus*. The dose to produce complete anesthesia lasting

4–18 hrs. was 40–54 mg. per kg., the anesthesia in fresh water fishes being slower in onset and more prolonged than in the salt-water fishes. The respiration rate fell markedly. O_2 intake also was below normal during anesthesia but increased after the fish had recovered. C. RIEGEL

Micrurgical studies in cell physiology. VII. The action of the chlorides of sodium, potassium, calcium and magnesium on vacuolated protoplasm. R. CHAMBERS AND R. B. HOWLAND. *Protoplasma* **11**, 1–18(1930).—Immersion and injection expts. on the grossly vacuolated protoplasm of *Actinosphaerium* and *Spirostomum* indicate that NaCl and KCl have a liquefying action; $CaCl_2$ and $MgCl_2$ are coagulants. The order of toxicity is KCl > NaCl > $MgCl_2$ > $CaCl_2$. M. H. SOULE

Vital coloring and the effect of poisons. TAKEO KŌNO. *Protoplasma* **11**, 118–56 (1930).—Paramecia, carefully handled to avoid injury, were treated with neutral red, indulin scarlet, Janus green, trypan and isamine blue and fuchsin S. Non-toxic concns. were used as detd. by the decadic method and an immersion period of 24 hrs. K. noted the influence of various accessory reagents on the staining properties of the dyes and activity of the animals. Six classes of these reagents were tried—narcotics, fixatives, diuretics, neutral salts, alkaloids and hormones—a total of over 50 different materials. Most of these scarcely influence the staining by basic dyes. The action of neutral dyes is affected only when they are very dil. Acid dyes do not color healthy cells. In some cases the reagent hinders the action of basic dyes. NH_4^+ is most effective in this respect. Occasionally the toxicity of dye plus reagent is greater or less than that of either alone. No present theory adequately explains the various results. A bibliography of about 70 references is included. M. H. SOULE

Iodine content of American marine animals. GULBRAND LUNDE, JENS BÖE AND KARL CLOSS. *J. Conseil Intern. Exploration Mer* **5**, 216–25(1930).—Analyses of marine animals from the west and east coasts of the U. S. (Calif. and Mass.) were made in order to det. the I content of animals from seas other than the Norwegian, and to compare this with the Norwegian results previously reported. A slightly modified von Fellenberg method was used. The results were compared with those of other investigators made on a number of invertebrates and teleosts of the American coasts. In some cases the values found varied greatly. The authors believed that these differences were related to fishing ground and time of collection, with the exception of haddock. An evident difference in I content of the teleosts off the Norwegian and American coasts was found. For nearly all of the species the Norwegian forms showed a higher I content. For haddock only, the figures were of about the same order. The skins of fishes off the American coasts contained a higher I content than the lean parts of the flesh. This had previously been found for the Norwegian coast fishes. G. E. Y.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Interpretation of bromatological analysis. A. BEYTHIEN, C. HARTWICH AND M. KLIMMER. *Anales oficina quím. provincia* **3**, 38–47, 118–25(1929); cf. *C. A.* **24**, 199.—Methods of analysis for detg. the purity and suitability for food purposes of spices, coffee, chocolate and eggs are given. L. E. GILSON

Microchemical detection of benzoic acid, salicylic acid and esters of *p*-hydroxybenzoic acid in foods and in medicaments. ROBERT FISCHER AND FRITZ STAUDER. *Mikrochemie* **2**, 330–6(1930).—Esters of *p*-hydroxybenzoic acid (nipagin and nipasole) have recently been recommended as preservatives for food and for drugs. The method of Weiss serves for the identification of napagin but requires too large quantities of reagents and of original material. A method has been developed, therefore, which can be carried out with smaller quantities and which serves not only for the detection of the Me, Et and Pr esters of *p*-hydroxybenzoic acid but for the detection of benzoic and salicylic acids as well. Of marmalade, fruit sirups, etc., take 1–1.5 g. and make slightly acid with HCl. If the material is lumpy, first triturate with a little hot water. If a fat, take 2–3 g. and digest it with 2–3 cc. of hot dil. $NaHCO_3$ soln., pour off the liquid and make it acid with HCl. Add a few cc. of ether and shake vigorously in a test tube. Pour off the ether ext. and evap. the soln. on a paraffin bath kept at 50°, using a small subliming tube to hold the ethereal soln. Finally cover the tube with a watch glass and heat the residue from the ethereal soln. by placing the narrow end of the subliming tube in the paraffin bath which is now heated to 60°. If benzoic acid is present, a sublimate of feathery crystals and characteristic plates will be obtained.

By changing the cover glasses, it is easy to get 3–4 samples of sublimate. To one portion add a drop of water, heat to dissolve the crystals, cool and add a tiny fragment of $Hg(OAc)_2$. Soon microscopic needles of Hg benzoate will form, starting at the crystal of original Hg salt. The crystals should not give any red color with Millon's reagent nor any violet coloration with $FeCl_3$. If the crystals are obtained, it must be remembered that benzoic acid may have been present in the original fruit juices and is not necessarily added as preservative. If no further sublimation takes place at 60°, raise the temp. to 70° but take care to keep the cover glass properly cooled. If crystals are now obtained, it indicates the presence of one of the esters of *p*-hydroxybenzoic acid. Add a little Millon's reagent and a raspberry-red coloration will appear quickly on heating if one of the esters is present. Salicylic acid gives a brown coloration with the reagent and benzoic acid no color. Det. the m. p. of the crystals, drying a short time over H_2SO_4 before making the test. Nipasol m. 97°; the Et ester m. 116° and nipagin m. 109–112°. The latter temp. is about 14° lower than is obtained in the Roth app. and as stated in the literature. Raise the temp. to 85° to test for salicylic acid, which can be identified by the cryst. appearance and the color test with 1% $FeCl_3$. W. T. H.

Contamination of food cooked or stored in contact with nickel-chromium-iron alloys. A. C. Titus, H. B. Elkins, H. G. Finn, L. T. Fairhall and C. K. Drinker. *J. Ind. Hyg.* **12**, 306–13(1930).—Several Ni-Cr-Fe alloys were tested by inserting strips of the metal into foods which were being cooked or stored. Detns. were made of the wt. changes of the alloys, of the character of the film formed on the metal, and of the degree to which traces of the constituent metals entered the food. The results show that the total dissolved metal is very small; Fe is the most readily dissolved of the 3 metals present in the alloys. For the foods investigated, the quantity of metal dissolved in the food at a H-ion concn. of 3 was no greater than at a concn. of 6. These Ni-Cr-Fe alloys are considered safe for cooking utensils. N. M. Naylor

Cereal chemistry in 1930. T. H. Fairbrother. *Food Manuf.* **6**, 5–7(1931). E. H.

An apparatus for the instantaneous measurement of the water content of grain without altering its composition. L. Montlaur. *Compt.-rend. acad. agr. France* **16**, 931–7(1930).—This simple app. is based on the fact that the capacity of a condenser is changed by placing a dielectric between the plates. The dielectric in this case is the grain and the value of the dielectric const. of the grain depends primarily on the quantity of moisture in the sample. Thus, on putting the sample of grain between the plates the capacity of the condenser is changed and this change referred to the proper curve will give the percent moisture in the sample. For a curve covering 0–20%, 1% humidity corresponds to a deviation of 5 ma. at the upper end of the scale. J. R. Adams

Wheats entered for the Royal Agricultural Society's show, 1930. G. W. Norris. *Agr. Gaz. N. S. Wales* **41**, 827–33(1930).—Results of chem. analyses and milling tests are tabulated. K. D. Jacob

New technic for the colorimetric study of wheat and wheat flour. P. Brière and J. Fleckinger. *Compt.-rend. acad. agr. France* **16**, 996–9(1930).—Dil. solns. of bromocresol green and phenosafranine are found to be valuable aids in studying both the grain and flour. The former imparts a blue color to the proteins while the latter stains the husks a rose color. J. R. Adams

Bound water of wheat-flour suspensions. R. Newton and W. H. Cook. *Can. J. Research* **3**, 560–77(1930).—The bound-water method was modified for use with flour suspensions and provided a simple means for the direct measurement of the approx. hydration of the colloidal constituents in dil. lactic acid. The av. hydration of the dry matter in 15% suspensions was in the region of 40 to 50%, the value being slightly higher in washed suspensions. Starch maintained a hydration close to 30% under all conditions investigated. The prepd. proteins, in dil. lactic acid, were hydrated about 85%. The calcd. hydration of the proteins as they occurred in the flour was about 100% in unwashed and 200% in washed suspensions. No significant differences were found by this method in the hydration of strong and weak flours, and it is thought that such differences as may exist are too small to be of major importance as factors in baking quality. The exptl. results are harmonized with the facts concerning viscosity and the behavior of bread dough by assuming micellar aggregation of the gluten. J. W. Shipley

Iodometry of flour products. II. K. Fuchs, W. Ruziczka and E. Kohn. *Z. Untersuch. Lebensm.* **59**, 573–85(1930); cf. *C. A.* **24**, 5384.—About 0.5 g. of the sample is digested with 15 cc. of 96% EtOH and 10 cc. of H_2O at 20°, 20 cc. of an alc. 0.2 *N*

soln of I and 190 cc. of water are added, and the excess of I is titrated with 0.1 *N* $Na_2S_2O_3$ soln. after 5 min. (I value), and after 24 hrs. (periodine value). The I and periodine values increase with the fineness of grinding of wheat and rye flours. There is good agreement between different millings of the same flour, and an advantage is claimed over the Pékar method in that results are unaffected by such bleaching agents as NO, benzoyl peroxide or Cl. The acid value usually decreases with increase in fineness of grinding. The acid value is detd. by titration of 5 g. of flour, after digestion for 30 min. at 20° with 10 cc. of EtOH and 100 cc. of H_2O, with 0.1 *N* NaOH soln. in the presence of phenolphthalein. Kolthoff's method for acidity detns. was found to be especially useful for fine, acidic flours, 5 g. being digested with 10 cc. of EtOH and 100 cc. of H_2O at 20°, and the mixt. titrated with a 0.1 *N* soln. of I in KI 30 min. after the addn. of 3 cc. of 10% KI, 2 cc. of 3% KIO_3 and 5 cc. of 0.1 *N* $Na_2S_2O_3$ solns. The p_H value is detd. colorimetrically on 0.5 g. of flour digested with 10 cc. of water and filtered after standing overnight. The p_H increases with the fineness of grinding. The above iodometric methods were successfully applied also to natural and prepd. oatmeals, to corn and bean meals and to barley and pea flours. C. R. FELLERS

Detection of corn cockle in flour and bread. R. FISCHER AND E. RIEDL. *Z. Untersuch. Lebensm.* 59, 595–8(1930).—The method depends upon the isolation of saponin by means of capillary analysis with a strip of filter paper contg. a band of cholesterol, which fixes the saponin as cholesteride. Shake a 5-g. sample for 6 to 20 hrs. with 20 cc. of H_2O, filter, centrifuge and place 10 cc. of the clear liquid in a cylindrical glass vessel, 10 cm. long and 4 cm. wide. Cut 1 end of a 20 × 3-cm. strip of filter paper to 5 cm. long and 1 cm. wide and place 0.05 to 0.1 cc. of a 1% soln. of cholesterol in EtOH or Et_2O on this portion so as to form a barrier 3 cm. from the end and 1 cm. long. Place the end of the paper strip so that it reaches to the bottom of the glass cylinder, let stand for 24 hrs., suspend in H_2O for 2–3 hrs., the cholesteride being thus washed by capillarity, transfer to water for 2 hrs., dry, heat with a little xylene, wash in Et_2O and place in blood gelatin. A blood corpuscle-halo is observed (cf. Kofler, *C. A.* 23, 4020) in 20 hrs. in a concn. of corn cockle of 1:17,000; in 15 hrs. for 1:10,000; and in 30 min. for 1:2500. Thus the method is roughly quant. With slight variations the method is applicable to the detection of corn cockle in bread. C. R. FELLERS

Baking tests of bread. RAFAEL ILLESCAS. *Rev. quím.* 6, 15–8(1930).—Practical tests are recommended. E. M. SYMMES

Study of the relative values of honey and sucrose in bread manufacture. W. F. GEDDES AND C. A. WINKLER. *Can. J. Research* 3, 543–59(1930).—Honey was substituted for com. sucrose in various straight-dough bread-baking formulas, and the doughs were fermented for varying times and proofed and baked in the usual manner. No significant difference in loaf vol., flavor or other bread characteristics could be detected, indicating that honey possesses no superiority over sucrose but is of equal value when compared on the basis of equiv. sugar content. The baking tests were supplemented by studies on the rate of gas production in doughs and also by detns. of the reducing-sugar content of the doughs at the end of the proof period. Rates of gas production were similar and the reducing-sugar contents of the doughs were of the same order. A comparison of the results obtained by the different baking formulas indicates the importance of considering the formula in relation to the apparent fermentation tolerance of a flour. No difference was observed in the rate of gas production in partially buffered yeast-honey and yeast-sucrose suspensions of equiv. sugar content prepd. in a manner to simulate conditions in fermenting bread doughs. Studies on the rate of inversion of sucrose by yeast showed that the rate of invertase action exceeds the speed of zymase action and indicated that sucrose inversion is not a limiting factor in the rate of gas production in bread doughs. An extension of the market for honey in the baking industry would seem to lie in the direction of increasing its use in sweet goods where its flavor, higher sweetening power and greater hygroscopicity are particularly advantageous. In bread manuf. these properties do not come into play since the relatively low percentage of sugar used is to a large extent removed by fermentation. J. W. S.

Emulsions. I. A. EICHSTADT. *Milchwirtschaft. Forsch.* 9, 388–95(1930).—The addn. of milk to fat gives an emulsion of milk in fat; the opposite order of addn. gives an emulsion of a creamy nature. Rapid addn. of fat or simultaneous mechanical admixt. gives a double emulsion. The first type is required for margarine emulsions, the stability of which is greater when coconut or hardened peanut oil is used, and when small quantities of emulsifiers are added. **II. Stability of emulsions in relation to viscosity of fat, surface tension and the formation of adsorption films.** W. MOHR AND A. EICHSTADT. *Ibid* 396–408.—The reasons for greater stability of certain

milk-in-fat emulsions are discussed. The formation of an adsorption film at the interface fat-skim milk is a factor. GEORGE R. GREENBANK

The effect of increasing the quantity of coconut and palm kernel meal in the ration on the fat content of the milk. F. HONCAMP, W. HELMS, G. KODDER AND A. PETERMAN. *Milchwirtschaft. Forsch.* 9, 161–78(1929).—There was some increase in fat content, but there is no proportionality between the amt. of fat in the ration and the fat content or yield of milk. GEORGE R. GREENBANK

Determination of the milk proteins. GEO. M. MOIR. *Analyst* 56, 2–9(1931).—The chemistry of casein and the state in which it exists in milk are discussed to show the desirability of using an acid reagent for the purpose of its analytical sepn. By mixing 90 ml. of *N* AcOH with 35 ml. of *N* NaOH, so that the acid and AcONa concns. were, resp., 0.44 *N* and 0.28 *N*, a mixt. of p_H 4.42 was obtained of which 5 ml. was added to 10 ml. of milk which had been dild to about 50 ml. A buffer soln. of this type can be used on milk of widely varying compn., but to obtain a max. pptn. of casein it was found best to add the soln. in 2 parts: first the acid and then the AcONa soln. Instead, therefore, of using only 1.5 ml. of 10% AcOH per 10 ml. of milk, it seems advisable to modify the A. O. A: C. "official" method, by adding 4.5 ml. of 0.25 *N* NaOAc after the acid has been added in a manner to be described later. W. T. H.

Detection of heated milk and a new method for the detection of pasteurization. S. ROTHENFUSSER. *Z. Untersuch. Lebensm.* 60, 94–109(1930).—The method (cf. *C. A.* 3, 459) is entirely revised. The Pb serum of the milk is prepd. by adding to 100 cc. of the sample the min. excess of basic Pb acetate soln. required to produce complete pptn. The mixt. is well shaken and filtered. The filtrate should contain no casein, fat, phosphates or citrates. The p_H is 6.6 to 6.7 and the acidity equiv. to 1 cc. of 0.25 *N* NaOH soln., and in the serum from fresh milk both peroxidase and diastase are present. For milk heated to a relatively high temp. "paratetrol sulfite" (1 g. p-$C_6H_4(NH_2)_2$.HCl in 12 cc. H_2O mixed with 4 g. guaiacol in 100 cc. 96% alc., made up to 150 cc. with alc., and treated with 30 drops of 20% $NaHSO_3$ soln.) is used as a reagent. To 10 cc. of serum or milk are added 4 drops of 3% H_2O_2 and 10 drops of the reagent. Raw milk or milk heated for 30 min. below 70° gives a violet ring immediately; milk heated for a short period above 79° or for a long period at 70–75° gives no color; while milk heated for 30 min. at 75° gives color after 1 min. Storage in ice for 14 days after heating did not affect the intensity of the color reaction. With milk pasteurized at 63° for 30 min., the action of the peroxidase is upset and it is necessary to utilize the diastatic activity of the serum. The test is made by shaking 30 cc. of the milk with 1.6 cc. of the Pb reagent in a conical centrifuge tube, adding 2 cc. of HCl-free trichloroethylene or $CHCl_3$, shaking the mixt. again and centrifuging. The clear serum, 10 cc., is then mixed with 1 cc. of starch soln. (specially prepd.), and after 15 hrs. at room temp., or 3.5 hrs. at 40°, 1.5 cc. of this is poured into a small tube and 1.5 cc. of 0.002 *N* I soln. added. A yellow color in the mixt. denotes a slight degree of heating, insufficient to destroy the character of the raw milk; brown indicates a short period of heating at 60–3° or a long period at 55°; red-violet, 30 min. at 60–3°; violet, prolonged heating at 63° (permanent pasteurization); and a full blue color, the complete absence of active diastase. Both methods are influenced by substances and treatments other than heating which affect the activities of the enzymes, but the results are considered strictly reliable. C. R. FELLERS

Solubility of milk powder and its significance. J. C. MARQUARDT. *Creamery and Milk Plant Monthly* 19, No. 12, 32–3(1930); cf. *C. A.* 25, 360.—A study of the soly. of skim milk powder has shown that ice cream and cream cheese quality are not affected by the soly. of the powder. Undesirable flavors in milk powders are not assocd. or related to the solubilities of the powders, but if the powders do have undesirable flavors such flavors are transmitted to the manufd. ice cream. Storage temps. ranging from 40 to 70°F. and humidity are minor factors in detg. the keeping quality of skim milk powders stored in sealed containers. The suitability of skim milk powder for ice cream and cream cheese manuf. is enhanced by storage in sealed containers. A slight decrease in soly. of skim milk powders is assocd. with exposure to light and air. H-ion concn. detn. with a limited no. of samples indicated that the powders changed slightly toward the acid side during storage. Chem. detn., rennet pptn. and phys. observations have shown that the nature of the insol. portion of powders may vary widely in different powders. However, it has been definitely shown that the insol. portion of highly sol. powders is protein while the insol. portion in highly insol. powders may be protein or sugar and protein in varying proportions. A. H. JOHNSON

The knowledge of the electrical conductivity of milk and its use in the detection of abnormal milk. O. DOUNHOFER AND F. MOSER. *Molkerei-Ztg.* (Hildesheim) 44,

149–54(1930).—A cond. of 52-54 × 10^4 is regarded as suspicious and of over 54 × 10^4, as abnormal; these studies were made on 350 samples of milk. The measurement was made at 18° and at an acidity of not over 8.5 Soxhlet-Hinkle. Formalin, xylene or toluene may be used as preservatives without effect. GEORGE R. GREENBANK

Frozen and thawed milk. W. KOENIG. *Molkerei-Ztg.* (Hildesheim) **44**, 289–91 (1930).—In partially frozen milk the frozen part after thawing has properties and compn. resembling those of watered milk. The f. p. and solids-not-fat are low. The fat is normal or may be high. In the unfrozen part the fat is often lower than normal and the solids-not-fat are high. Completely thawed and well mixed milk is normal. GEORGE R. GREENBANK

Analyses of spoiled milk. P. GUARNIERI. *Atti III congresso naz. chim. pura applicata* **1930**, 482–3.—Fat and total nitrogenous substance are detd. The latter varies from 3.35 to 3.80. The ratio of total fat to total nitrogenous substance is normally above 0.8. E. M. SYMMES

Research as applied to dairy engineering. H. A. RUEHE. *Creamery and Milk Plant Monthly* **19**, No. 12, 27–9(1930).—R. outlines the effects which research has had in changing methods of operation in the various branches of the dairy industry and suggests the directions which future research may take. The effects of this research are considered to be most notable in the fresh milk and ice cream industries. A. H. JOHNSON

A review of the literature on metals in the dairy industry. OSTERBURG AND T. LIEPUS. *Milchwirtschaft, Literaturber.* **36**, 181-210(1930).—This is a study of plain and tinned Cu, tinned Fe, Al and its alloys, Cr and Ni steel, Ni, bronze, metallic coating and glass-lined equipment. The properties of the different metals and their value in the various types of equipment are discussed. A bibliography of over 200 references is given. GEORGE R. GREENBANK

Whipping properties of chocolate ice cream. W. H. E. REID. *Creamery and Milk Plant Monthly* **19**, No. 12, 101-7(1930).—Sugar influences the whipping properties of a chocolate ice cream mixt. by depressing the ability of the mixt. to incorporate air. The decrease in this ability prolongs the freezing time and causes difficulty in obtaining the desired overrun. Proper balancing of the chocolate mixt. with respect to the sugar content will furnish a mixt. that can be whipped to the same overrun in the same freezing time as obtains for vanilla ice cream The type of chocolate paste and the time of adding it to the mix reflect directly on the whipping properties of the mix. The ability of the chocolate mixt. to whip to the desired overrun affects the body and texture of the finished ice cream to a marked degree. A. H. JOHNSON

The content of salt in cheese. F. MÜNCHBERG. *Milchwirtschaft. Zentr.* **59**, 201–2 (1930).—From 1 to 2 g. of cheese is boiled with 10 cc. of halogen-free HNO_3. (d 1.40) and 10 cc. of 0.1 *N* $AgNO_3$. Ten % $KMnO_4$ soln. is gradually added until the soln. is clear. The soln. is dild. to 150 cc. with distd. H_2O and cooled. Two cc. of a satd. soln. of $Fe_2(SO_4)_3$ and $(NH_4)_2SO_4$ is added and the excess of Ag titrated with 0.1 *N* NH_4CNS. One cc. of 0.1 *N* $AgNO_3$ equals 0.005856 g. NaCl. As the NaCl content should be based on the dry weight the moisture should be detd. by mixing with sand and drying to const. weight at 105°. The sample should be stirred frequently while drying. Tables show the moisture and NaCl in various kinds of cheese. G. R. G.

Process and package cheese discoloration by tin foil. A. E. OTTICKER. *Molkerei-Ztg.* (Hildesheim) **44**, 583–4(1930).—O. compares Zn and Sn foil on different types of cheese. Acidity is not the principal cause of discoloration, as it occurs often on mild cheese which is low in acid. O. recommends that Zn foil be used instead of Sn. His analysis shows 0.03–0.05% Pb and 3% Sb. GEORGE R. GREENBANK

Acidity changes associated with the keeping quality of apples under various storage conditions. H. H. PLAGGE AND FISK GERHARDT. Iowa Agr. Expt. Sta., *Research Bull.* No. **131**, 342-58(1930).—Measurements were made on Grimes Golden and Jonathan apples of total titratable acid, p_H, and sp. gr. of the juice. Though total acidity declined rapidly in the Grimes variety during 2 weeks' delay in the orchard, the p_H value remained practically const. However, after 3 weeks, the p_H abruptly dropped, the drop occurring simultaneously with the appearance of soggy breakdown disease. In Jonathan apples, the p_H was decidedly more const., indicating a difference in buffer stability between the 2 varieties. An inverse relationship existed between the % of total acid loss and the susceptibility toward Jonathan spot. A low acid loss during cold storage usually produced a high % of spotted tissue. Total acidity decreased more in Grimes apples during the 2–3 weeks' delayed orchard storage than during the entire period held in cold storage. During storage 2 conditions influence the total amt. of acid lost: (1) initial acid content when stored and (2) the storage temp. Less total

acid was lost at 0° than at 2–3°. To prevent soggy breakdown in Grimes apples, the fruit must be picked when mature and immediately placed in cold storage. A decided increase in the sp. gr. of the juice from Grimes apples during delayed storage at the orchard indicates definite changes in the metabolism of the fruit. Little or no change in sp. gr. occurred in cold-storage fruit which had previously been held in the orchard for 2–3 weeks. On the other hand, the juice of Jonathan apples was relatively const. irrespective of a delayed storage period in the orchard. The storage capacities of some varieties of apples may be forecast by changes appearing in the sp. gravities of their juices. C. R. FELLERS

Canning quality of certain commercially important Eastern peaches. CHARLES W. CULPEPPER AND JOSEPH S. CALDWELL. U. S. Dept. Agr., *Tech. Bull.* 196, 45 pp. (1930).—Chem. and phys. examns. were made of the more important Georgia varieties of peaches, and these data were correlated with canning quality. Complete analyses were made at short intervals from the immature stage to the fully ripe stage of Carman, Belle, Hiley, Yellow Hiley, Arp, Early Rose and J. H. Hale varieties. In all the varieties, the development of full characteristic flavor was delayed until the fruit was fully ripe and rather soft. This increase in palatability was attributed in part to progressive increase in sugars and decrease in total acidity and astringency, and in part to progressive formation of the characteristic flavoring substances and the soln. of the middle lamellae of the cell walls, thus permitting better contact of the cell contents with the organs of taste. Peaches were satisfactorily *lye-peeled* by immersing in a 2% NaOH soln. for 30–60 sec. J. H. Hale and Elberta proved superior for canning purposes. C. R. FELLERS

Composition of fruits as used for jam manufacture in Great Britain. T. MACARA. *Analyst* 56, 35–43(1931).—The analytical data published by the British Assoc. of Res. for Cocoa, Chocolate, Sugar, Confectionery and Jam Trades will be of interest to food chemists. The method of analysis is described and the results of hundreds of analyses on all kinds of fruit are tabulated. W. T. H.

Effect on foods of fumigation with hydrogen cyanide. G. W. MONIER-WILLIAMS. *Analyst* 56, 46–8(1931).—The results of many analyses indicate the effectiveness of ventilation in removing excess HCN after fumigation to destroy insects and vermin pests in food, except in dried and liquid milk, dried fruit and possibly cheese. Absorption of HCN is greatest in moist, finely-divided, unwrapped foods. Orange and apple skins resist absorption, while peaches and bananas are more easily penetrated. Cooking removes nearly all the absorbed gas. Foods treated with less than 1 vol. of HCN in 200 vols. of air and subsequently exposed to fresh air usually retain less than 20 parts HCN per million of food. Fertile hen eggs are killed by fumigation with 1% HCN at 3° in 4 hrs., although the quantity of HCN absorbed is very small. W. T. H.

Large-scale experiments in sulfuring apricots. E. M. CHACE, C. G. CHURCH AND D. G. SORBER. *Ind. Eng. Chem.* 22, 1317–20(1930).—Apricots were treated with SO_2 in thermally controlled boxes under varying conditions of gas concn., temp. and time of exposure. As the gas concn. increases, the retention of SO_2 by the fruit rapidly increases. The SO_2 retention also increases during the entire time of exposure and this is particularly rapid in the first $^1/_2$ hr. Good fruit results from exposure for 2 hrs. in 3% gas. Temp. has very little effect. The best results are obtained at 100–110°F., while above 120°F. the product has a reddish tinge. J. R. ADAMS

Mineral elements in bean sprouts. LANG-RU TING. *Science* (China) 14, 1631–46 (1930).—Bean sprouts are everyday items in the Chinese dietary, and are important sources of mineral elements in nutrition. Soy-bean sprouts contain approx. 0.1% CaO and 0.3% P_2O_5; mung-bean sprouts, 0.05% CaO and 0.2% P_2O_5. The Ca and P contents of both varieties can be increased by sprouting in water contg. not less than 0.5% CaO and 0.2% P_2O_5. WM. H. ADOLPH

Effect of pure culture inoculation on the quality and chemical composition of sauerkraut. CARL S. PEDERSON. N. Y. State Agr. Expt. Sta., *Tech. Bull.* No. 169, 3–29(1930).—Of 72 exptl. batches of sauerkraut, 25 were inoculated with pure cultures of some one of the following organisms: *Streptococcus lactis, Leuconostoc mesenterioides, Lactobacillus buchneri, Lactobacillus pentoaceticus, Lactobacillus delbrücki, Lactobacillus plantarum,* and *Lactobacillus brassicae.* Normal sauerkraut completed its fermentation at 24–7° in 2–3 weeks, the resulting acidity being 1.5% (lactic). The EtOH content was usually less than 0.6% and the ratio of volatile to non-volatile acid was about 0.24. Inoculation with pure cultures of *Streptococcus lactis* improved the quality of the kraut and did not affect the by-products produced. *L. brassicae, L. cucumeris* or *L. plantarum* when used for inoculations gave detrimental results, the

quality of the kraut being poor and the predominant fermentation of the pure lactic acid type with little AcOH, EtOH or CO_2. Krauts inoculated with pure cultures of *L. pentoaceticus* were fair in quality but had an abnormal flavor and an abnormally high volatile acid content. Many of the pure culture krauts were particularly susceptible to yeast spoilage. For the present, the manuf. of kraut by pure culture methods is not advocated. A bibliography is included. C. R. FELLERS

Analysis of sea cucumber. HSI-CHEN LIU. Yenching Univ. *Science* (China) **14**, 1308–24(1930).—Analyses of sea cucumber, the Chinese delicacy which appears at banquets under the name *sea slug*, gave: H_2O 8.64, protein 63.75, fat 0.82, ash 9.86 and N-free ext. 16.93%. WM. H. ADOLPH

The groups of extractives in coffee. CIUPKA. *Chem.-Ztg.* **54**, 803(1930).—The following figures give, resp., values for natural ext. of a raw Costa Rican coffee expressed in percentage of dry substance, the ext. of the roasted residues expressed in percentage of dry matter, and the ext. content of a roasted Costa Rican coffee expressed in percentage of the dry raw coffee: (1) Total water-sol. exts. 28.2, 4.1, 22.6; alc.-sol. fraction 1.6, 0.12, 0.06; ether-sol. fraction 0.1, 0.04, 0.45; (*a*) residue from (1) dried and extd. with alc. 16.7, 0.4, 11.8; (*b*) residue from (1) dried and extd. with ether 14.2, 0.5, 11.5; (*c*) residue from (1*a*) dried and extd. with ether 0.12, 0.15, 0.48; (*d*) residue from (1*b*) dried and extd. with alc. 0.9, 0.4, 1.3; (2) total ether-sol. ext. 16.2, 0.4, 14.8; (*a*) residue from (2) dried and extd. with alc. 5.1, 0.3, 6.0; (*b*) residue from (2*a*) dried and extd. with water 22.1, 4.0, 18.2; (3) total alc.-sol. ext. 21.2, 0.7, 18.3; (*a*) residue from (3) dried and extd. with ether 0.35, 0.25, 0.5; (*b*) residue from (3*a*) dried and extd. with water 22.0, 3.7, 19.3. RUSSELL C. ERB

Maltol and its colorimetric determination in malt coffee. T. MERL. *Z. Untersuch. Lebensm.* **60**, 216–7(1930).—Maltol was prepd. by heating a prepn. of malt diastase, 1:100, at 180–200°, and was sepd. by steam distn. and extn. of the distillate with Et_2O. The Et_2O ext. was dried over Na_2SO_4, evapd. under reduced pressure, and the maltol obtained as crystals, m. 153–5°. Other plant materials such as larch and other barks yield maltol if heated, especially if collected in the spring. It gives characteristic phenol reactions. To det. maltol in malt coffee, grind 50 g. so as to pass a 0.5-mm. sieve, digest 10 g. with 5 cc. of H_2O for 1 hr., then mix with 3 cc. of H_2O, 15 g. of sand and 1.5 g. of blood charcoal, and ext. for 5 hrs. with CCl_4 in a Soxhlet app. Shake the ext. with 100 cc. of H_2O contg. 3 drops of 10% $FeCl_3$ soln. and 2 cc. of *N* HCl, and compare the color in a Duboscq colorimeter with that produced in the same way from a standard soln. of salicylic acid. One mg. of maltol per 100 cc. in a layer 54 mm. deep matches 1.75 mg. of salicylic acid per 100 cc. in a layer 25 mm. deep. Malt coffees prepd. by a no. of different methods gave maltol contents of from 1 to 9 mg. per 10 g.; those made from dried and roasted barley, as distinct from normally roasted barley, always gave a value of less than 6 mg. per 10 g. This figure is proposed as the basis of a test for the specification of malt coffee, namely that it should contain at least 70% of half-grown barley corns, the figures actually obtained for artificial mixts. contg. 25, 50 and 75% of dried roasted barley being 5.6, 4.2 and 2.7 mg., resp. The biol. function of maltol as an antioxidant for fats and oils is briefly discussed. C. R. FELLERS

Digestibility and food value of tapioca and fish fodder meal. H. EDIN, G. KIHLÉN AND AD. GUSTAFSSON. *Kgl. Landtbruks-Akad. Handl. Tid.* **69**, 882–904(1930).—The digestibility coeff. of the org. substance of finely ground tapioca was 94.5, of crude protein content —26, of crude fat 80, of crude fiber 47 and of N-free ext. 99. The negative value for crude protein shows that the digestible crude protein of tapioca is much too low. The food value was 126 fodder units and 95 kg. starch value per 100 kg. of org. substance. Feeding with tapioca did not raise the available supply of digestible albumin in the swine tested, but decreased it 0.5%. The digestibility of coarse tapioca was 2% less, and it was not eaten as readily. The av. digestibility coeff. of fish meal was 78 for org. substance and 85 for crude protein. Utilization was not so good on forced feeding. An av. of 99% crude fat content was digested and for N-free ext. —170 was found. E. M. SYMMES

The yields and losses in raw and digestible nutritive matter during the second and third mowing of clover and meadow grass according to experiments at the Königsberger Animal-Raising Institute. W. KIRSCH. *Tierernähr.* **1**, No. 1, 104–18(1929).—Digestible protein increases on the second and third mowing in clover and clover grass mixt. The starch value is also increased. The time between mowing varies, but usually averages 1–2 months. Similar increases are noted in meadow grass. Tabular data are presented with corrections for losses in nutritive matter due to drying, mechanical treatment of the grasses, fermentation of the wet grasses, etc. RUSSELL C. ERB

I content of American marine animals (LUNDE, *et al.*) **11I. Measuring the H-ion concentration in opaque colloidal solutions** (Ger. pat. 510,623) **13.**

Spark-discharge apparatus for generating a bleaching gas for flour, etc. FRITZ STUFF. Ger. 510,419, Dec. 23, 1927.

Thermometer for dough and like pasty masses. FRITZ KEMPTER. Ger. 510,371, Nov. 10, 1927.

Bread. VOLKMAR KLOPFER and DR. VOLKMAR KLOPFER'S NAHRUNGSMITTEL-A.-G. Fr. 688,834, Jan. 25, 1930. See Ger. 509,033 (*C. A.* **25**, 750).

Milk. HEINRICH BÜNING. Fr. 36,671, April 9, 1929. Addn. to 645,941 (*C. A.* **23**, 2224). The content of fat in milk is increased by injecting 30-40 parts of warm fat into 60–70 parts of milk under high pressure. The milk is then or previously homogenized with egg yolk with heat under pressure.

Colorimetric apparatus for determining the acidity of milk. CHRISTIAN HACKMANN. Ger. 503,245, Sept. 30, 1927.

Preserving eggs. HENRIETTE BELHOMMET (NÉE LYS). Fr. 691,104, Mar. 5, 1930. See Belg. 358,655 (*C. A.* **24**, 901).

Apparatus for determining the starch content of potatoes. ANTON ARLAND. Ger 510,374, Aug. 26, 1926. The app. measures the increase in vol. when a given wt. of potatoes is treated with a given vol. of water.

Dies for macaroni manufacture. FREDERICK PENZA. U. S. 1,788,689, Jan. 13. Structural features.

Edible salt. COMPAGNIE DE PRODUITS CHIM. ET ÉLECTROMÉTALLURGIQUES ALAIS, FROGES ET CAMARGUE. Fr. 689,943, Apr. 26, 1929. An edible salt in liquid form is made by concg. sea water to 25–34° Bé. and eliminating partially or wholly the $MgSO_4$ either by cooling or converting it to $MgCl_2$ by means of an alk. earth chloride.

Edible salt. PAUL WOOG. Fr. 36,795, Feb. 18, 1929. Addn. to 674,401 (*C. A.* **24**, 2556). An edible salt is made by adding to NaCl, either solid or in soln. finally evapd., the salts contained in sea water and separately prepd. If a product not affected by moisture is desired, the Mg salts are converted to carbonates.

Confectionery. AKT.-GES. FÜR MEDIZINISCHE PRODUKTE. Ger. 510,318, July 17, 1928. Addn. to 509,034 (*C. A.* **25**, 751). To margarine for use in the manuf. of puff pastry there is added a small quantity of a mixt. of malonic acid with another dicarboxylic acid, *e. g.*, tartaric or citric acid. Salts of the acids may also be used.

Tea. J. P. CROFT. Brit. 334,224, March 1, 1929. Ordinary tea is treated with a soln. of theine or caffeine, to increase its strength and reduce the excess of tannin. Details of treatment are given and mention is also made of the production of malted tea.

Coffee. KARL LENDRICH. Fr. 688,638, Jan. 21, 1930. Grains of coffee are improved by submitting the green coffee grains to hydrolysis for at least an hr. with steam under pressure. A small quantity of an alkali or a mineral acid may be added to the coffee before the treatment.

Coffee substitute. JOSEPH F. EURY. Fr. 689,951, April 29, 1929. A product which may be used as a substitute for or addn. to coffee is obtained by wetting coffee marc with a very dil. soln. of a fixed or volatile alkali, free or carbonated, then heating in an autoclave to about 120° for $^1/_2$ hr. and afterward drying.

Apparatus for treating waste animal or fish products with steam or solvent vapor in a continuous manner. AUGUST SOMMERMEYER. Fr. 690,048, Feb. 15, 1930.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Chemical resources and industries of the South. LAUREN B. HITCHCOCK. *Ann. Am. Acad. Political and Social Sci.* **153**, 76–83(1931).—Twenty index chem. industries of national character and of 15 southern states are used in a study based on the 1927 Census of Manufactures. Twenty-one % of Southern industry proves to be devoted to chem. manufactures; 11% of all U. S. industry is chem. Twenty-six % of all U. S. chem. manufactures originate in the South. Factors influencing development in this region are cited. L. B. HITCHCOCK

Cornstalks as an industrial raw material. O. R. SWEENEY AND LIONEL K. ARNOLD. Iowa Eng. Expt. Sta., *Bull.* **98**, 48 pp.(1930). E. H.

The development of the iodine industry and its present industrial position. W. ROMAN. *Z. angew. Chem.* **44**, 9–15(1931). E. H.

What is an insulator? A. MEISSNER. *Z. Physik* **65**, 158–66(1930).—The characteristic of an insulator is: a material consisting of elementary cells contg. pos. and neg. ions, held together by high-valency forces. This is brought into evidence by the process of "formation", which may be achieved by exposing the molten insulator (*e. g.*, asphalt) to a high elec. field on solidification. The piezoelec. moment due to such a formation is often 50 times larger than that of quartz. Disturbing effects such as transition of charges from the electrodes into the insulator or the migration of ions in the insulator and the space charges resulting therefrom are discussed with special reference to *mica*. Catalytic oxidation. THE SELDEN CO. Fr. 689,610, Feb. 8, 1930. Catalytic oxidations in the vapor state of org. compds. to intermediate products, or the removal of org. constituents by preferential oxidation is carried out by mixing with the vapors to be oxidized one or more supplementary vapors of an org. or nuclear substance, which is more easily or less easily oxidized than the substance to be oxidized, and passing the mixt. over a catalyst at reaction temps. By the above method the reaction is more easily controlled. Several examples are given.

Catalytic processes. I. G. FARBENIND. A.-G. Fr. 688,927, Jan. 27, 1930. In treating gases catalytically under pressure, mixts. of lubricating oil from the circulating pumps, etc., are removed from the gases by solid absorption agents such as active charcoal or SiO_2 before they reach the catalysts.

Endothermic operations. FRIED. KRUPP GRUSONWERK A.-G. Fr. 689,456, Feb. 5, 1930. In endothermic operations in which the substance to be treated is charged into a furnace with fuels and in which the amt. of air necessary for the reaction is blown wholly or in part through the charge, the furnace is displaced in a continuous or discontinuous manner and the mixt. of fuel and substance to be treated is caused to pass before different rows of air blowers placed one behind the other. Cf. *C. A.* **24**, 2215.

Purification of gases. COMPAGNIE FRANÇAISE DE PRODUITS ORGANOCHIMIQUES (Anciennement soc. anon. des Engrais et Noir animal). Fr. 36,982, May 28, 1929. Addn. to 636,162 (*C. A.* **23**, 223). In the app. of the prior patent a part of the purified cooled gases coming from a cooler placed after the first absorber is diverted for the purpose of cooling the absorbent charcoal. The operation is thermometrically controlled.

Gas purification. HUMPHREYS & GLASGOW, LTD. Fr. 689,970, Feb. 14, 1930. Gas is purified in an ascending current by projecting oil in a finely divided state into the gas in the direction of flow of the gas; the path of the mixt. is lengthened for a sufficient distance to allow the oil to agglomerate into drops and fall back into the current of gas. An app. is described.

Drying gases. DEUTSCHE GLÜHFADENFABRIK RICH. KURTZ & PAUL SCHWARZKOPF G. M. B. H. Ger. 510,916, Apr. 21, 1926. The gases are led through porous walled tubes surrounded by jackets contg. concd. H_2SO_4.

Filtering gases. METALLGES. A.-G. (Adam Arras, inventor). Ger. 512,222, Feb. 12, 1930. This relates to the supervision of gas-filtering plant by leading a portion of the filtered gases to an instrument for indicating and recording any residual dust, the test portion being directed against the instrument under pressure through a fine nozzle. The improvement consists in reducing the vol. of the test portion, and making good the vol. by clean air or gas, with a view to avoiding blockage of the nozzle.

Moistening gases. SIEMENS-SCHUCKERTWERKE A.-G. (Carl T. Buff, inventor). Ger. 510,330, July 10, 1929. A portion of the gases to be moistened is continuously by-passed at a steady rate through a cooler in which a predetd. part of its moisture content is condensed, a moistening device for the gases being automatically regulated in accordance with the amt. of condensate obtained per unit of time. App. is shown. Reference is made to the moistening of blast-furnace gases, etc., prior to elec. pptn.

Apparatus for conserving and gasifying liquefied gases. SOC. L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS GEORGES CLAUDE). Fr. 690,573, Apr. 30, 1929.

Purifying solutions. SOC. ANON. MAXIMINE. Fr. 690,483, Feb. 24, 1930. Solns contg. colloidal impurities such as impure *sugar solns.* are purified by means of an active colloidal C in the state of a "sol," extremely finely divided, kept in its original moist state and used with a content of water of 50-90%. The C is prepd. by finely powdering org. substances, dissolving as completely as possible and hydrolyzing under pressure. The reaction mass is heated to produce evapn. of water to a thick consistency and to destroy the carbonaceous materials, and then in a closed vat under a pressure of 3-5 atm. to a temp. of 200-300°.

Sterilizing liquids. GEORGE LAKHOVSKY. Fr. 688,887, April 13, 1929. Liquids are sterilized by introducing into the liquid a metal such as Ag, which by contact with the bacteria forms a short-circuit and by thus preventing the bacteria oscillating kills them.

Determining the viscosity of liquids. RICHARD V. DALLWITZ-WEGNER. Ger. 510,624, Jan. 10, 1926 and 510,625, Jan. 19, 1926. The viscosity is determined by measuring the pressure differences at the ends of capillary tubes through which the liquid is passing.

Distillation. I. G. FARBENIND. A.-G. Fr. 689,822, Feb. 13, 1930. In distg. under reduced pressure, particularly substances of high b. p., the gaseous space of the distillate receiver is connected to the still by a pipe dipping into the liquid to be distd., and the gas in the app. is redirected into the liquid by a pump interposed in the pipe

Measuring the hydrogen-ion concentration in opaque colloidal solutions. N. GERBER'S CO. M. B. H. Ger. 510,623, Mar. 22, 1929. The colloid is pptd. and the remaining turbidity removed by a dispersion agent of higher sp. gr. than that of the liquid. The whole is then centrifuged and the clear liquid tested for its p_H value by indicators in the usual way. The *method is suitable for milk, cream, etc.*

Method and plant for regulating the under-pressure in evaporators connected to condensers. METALLGES. A.-G. Ger. 512,221, April 7, 1927.

Introducing powdered material into vessels under pressure. I. G. FARBENIND. A.-G. Fr. 690,534, Feb. 25, 1930. In operations such as destructive hydrogenation under high pressure, powd. coal or other powd. substance is introduced into a vessel

kept under pressure through an intermediate chamber (for measuring the amt.), the whole space of which is filled by a sliding compressor before communication between this chamber and the pressure chamber is broken.

Operating furnaces with working media of explosive character. JAMES L. MCFARLAND (to General Elec. Co.). U. S. 1,789,187, Jan. 13. A furnace such as may be employed for brazing, annealing, etc., is initially heated substantially to its operating temp. while filled with air, then purged with a non-explosive medium such as a mixt. of N and H and then supplied with its working medium, such as H. Various structural details are described.

Canister for respiratory apparatus. RANDOLPH MONRO and JOHN C. GOSHORN. U. S. 1,789,262, Jan. 13. Structural features.

Removing toxic gases including cyanogen chloride from air (as in canisters of respiration apparatus). PAUL O. ROCKWELL. U. S. 1,789,194, Jan. 13. The gas is passed through a layer of granular activated C impregnated with $(CH_2)_6N_4$, a layer of granular alkali material such as pumice treated with caustic alkali, and another layer of substantially dry granular activated C impregnated with $(CH_2)_6N_4$.

Refrigerating agents. FRIGIDAIRE CORP. Fr. 689,618, Feb. 8, 1930. Hydrocarbon derivs. such as $CHFCl_2$, $CFCl_3$, CF_2Cl_2, CHF_2CH_2Cl and $CHF_2.CHFCl$ are used for producing cold in refrigerators.

Materials for submarine cables. BELL TELEPHONE LABORATORIES, INC., and WESTERN ELECTRIC CO., LTD. Brit. 334,553, June 5, 1929. Strands which are insulated from each other along most of their length are connected at intervals, suitably by blocks of solder or Cu-Zn alloy. A coating of Cu oxide on the strands may serve as the intervening insulation. Cf. *C. A.* **24**, 5899.

Plastic masses for heat insulation. RHEINHOLD & CO. VEREINIGTE KIESELGUHR- UND KORKSTEIN-GES. and JOSEPH S. CAMMERER. Ger. 512,326, Oct. 22, 1927. Powd. insulating materials are mixed with colloidal earth of a kind stated to be known in America as clayoid.

Rubber electric insulation. W. S. SMITH, H. J. GARNETT, J. N. DEAN and H. C. CHANNON. Brit. 334,587, June 6, 1929. Non-rubber substances are removed from rubber by heating it under pressure in a solvent of low b. p. such as benzene or benzine, decanting or filtering, and removing the solvent from the product as by steam-blowing. For insulating submarine cables, the purified rubber is hardened by vulcanization or by admixt. with gutta-percha or balata (which may be purified as described in Brit. 307,390 (*C. A.* **23**, 5255)) or with a high m.-p. low-ash bitumen low in free C as described in Brit. 322,208 (*C. A.* **24**, 2816).

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Surface water supply of the United States 1926. II. South Atlantic slope and Eastern Gulf of Mexico basins. NATHAN C. GROVER, A. H. HORTON, J. J. DIRZULAITIS, E. D. BURCHARD AND W. R. KING. *U. S. Geol. Survey Water-Supply Paper* **622**, 118 pp. (1930); cf. *C. A.* **24**, 3844. E. H.

Surface water supply of the United States 1927. IV. St. Lawrence River basin. NATHAN C. GROVER, S. B. SOULE, H. E. GROSBACH, LASLEY LEE, A. W. HARRINGTON AND H. B. KINNISON. *U. S. Geol. Survey Water-Supply Paper* **644**, 156 pp. **IX. Colorado River basin.** NATHAN C. GROVER, ROBERT FOLLANSBEE, A. B. PURTON AND W. E. DICKINSON. *Ibid* 649, 99 pp. Cf. *C. A.* **25**, 756. **X. The Great basin.** NATHAN C. GROVER, A. B. PURTON, H. D. MCGLASHAN, F. F. HENSHAW, G. H. CANFIELD AND ROBERT FOLLANSBEE. *Ibid* 650, 97 pp. (1930). E. H.

Public water supplies in British India. HAROLD E. BABBITT. *Eng. News-Record* 105, 678–82(1930).—Conditions in general relative to water supply in British India are discussed, and the supply systems of Bombay, Rangoon and Calcutta are described briefly. Most supplies are inadequate, expedients adopted under these circumstances being low pressures and intermittent supply. The latter is not very effective, and with both methods there is danger of contamination. It has been found that even where mains are always under some positive pressure, suction may be created in a service pipe because of high-velocity flow in the main, the action being similar to a jet pump. Most supplies are municipally owned. Nearly all cities are sewered, the sewage being discharged directly into rivers without treatment; this necessitates filtration of all supplies derived from such sources. Slow sand filters are widely employed and stand in high

favor. Algae growths are a problem. All surface supplies are chlorinated.
R. E. THOMPSON

Lake Monte (Guaminí, Argentina). Character and properties of its waters. CARLOS A. GRAU. *Anales oficina quím. provincia* (Buenos Aires) **3**, 1-26(1929).—Numerous complete analyses are given. The water averages about 2% salts, principally chlorides, sulfates and carbonates of Na and K. Fish are abundant. L. E. GILSON

Water supply scheme of Yallourn (Victoria). L. T. GUY. *Proc. 1st Commonwealth Conference on Pub. Health Eng.*, Dept. Health (Australia) Service, *Publication* No. **2**, 37–62; *U. S. Pub. Health Eng. Abstracts* **10W**, 92(Sept. 6, 1930).—The treatment for a town of 1000 consisted of dosage with alum, followed by sedimentation for 9–15 hrs. The p_H value of the water is adjusted to obtain optimum coagulation conditions. From 2.0–2.5 gr. per gal. of alum together with a retention period in the sedimentation basins up to 13 hrs. gives very good results. Chlorination has been found to be unnecessary. C. R. FELLERS

The drinking water problem in Nanking. G. L. KUO. *Chem. Ind.* (China) [2], **5**, 58–67(1930).—Nanking has no modern water supply system. Analyses indicate that river water is preferable to well water. Improved methods are suggested for city-wide transportation for domestic supply. WM. H. ADOLPH

Progress in water supply and purification during the past year. NORMAN J. HOWARD. *Contract Record and Eng. Rev.* **44**, 1625-32(1930).—cf. *C. A.* **24**, 1687.—An extensive review of progress during 1930 in the waterworks field. Noteworthy advances were the more widespread employment of softening and the extending use of the ammonia-chlorine process for taste prevention. Many large water-works construction programs are in progress in Canada. R. E. THOMPSON

Experimental studies of water purification. V. Prechlorination in relation to the efficiency of water-filtration processes. H. W. STREETER AND C. T. WRIGHT. *U. S. Pub. Health Repts.* **45**, 3105–28(1930); *J. Am. Water Works Assoc.* **23**, 22–52(1931); cf. *C. A.* **24**, 4878.—*Conclusions.*—(1) Raw-water prechlorination, when properly controlled, affords an effective and economical means of reënforcing the bacterial efficiency of rapid-sand water-filtration processes, the expts. having indicated that the permissible density of *B. coli* in the raw water could be slightly more than doubled by use of this measure. (2) Maintenance of a controlled low residual Cl in the applied water, averaging 0.05 p. p. m. and not exceeding 0.10 p. p. m., gave more consistent and, in general, more satisfactory results than did superchlorination, with a high residual Cl. (3) The bacterial efficiencies of filtration and of postchlorination appear, from these observations, to be measurably reduced as the result of prechlorination. (4) Although the length of filter run was not increased by prechlorination under the conditions of these expts., the development of growths of microscopic organisms was perceptibly retarded by this treatment. (5) The application of prechlorinated water to rapid sand filters appears to lower the bacterial content and the biochem. O demand of the filtering medium. Variations in both of these elements were found to bear a fairly definite relation to concurrent variations in the residual Cl of the applied water. More general observations made in the course of the expts. confirmed the prevalent impression that it is advantageous to prechlorinate before, rather than after, preliminary sedimentation in order to utilize the stabilizing effect of basin treatment prior to applying prechlorinated water to filters. They also indicated, however, that even with the stabilizing influence of such basin treatment, careful technical supervision and lab. control are necessary to maintain a relatively const. Cl content of water applied to filters, which appears to be a desirable condition for consistently effective filtration. Although the ability of well-ripened filters to absorb excessive amts. of Cl for considerable periods of time constitutes a valuable operating factor of safety, insofar as the production of overchlorinated effluents is concerned, any undue burdening of filters with excessively chlorinated water may be expected, as shown in these studies, to result in a measurable impairment of their bacterial efficiency. The main advantage of prechlorination, from the viewpoint of this study, may be summed up as being its effectiveness and relative economy as a measure for reënforcing the over-all bacterial efficiency of the rapid sand filtration process, when considered as a whole. Its principal disadvantage appears to be its tendency to cause a perceptible decrease in the bacterial efficiency of filtration and of postchlorination. From a practical standpoint this advantage appears, from the study herein described, to be outweighed by the advantage above indicated, though it should be taken into account in casting up a balance sheet of performance to be expected in applying this method of treatment. J. A. KENNEDY

Purification of highly turbid waters. JOHN D. FLEMING. *J. Am. Water Works Assoc.* **22**, 1559–76(1930).—See *C. A.* **24**, 5088. D. K. FRENCH

Observations on suspended matter in the San Juan River. C. S. HOWARD AND S. K. LOVE. *Eng. News-Record* **105,** 620–1(1930).—Data obtained in studies carried out in 1928 and 1929 are given. At certain times the San Juan is one of the muddiest rivers in the U. S. In general, the river carries larger percentages of suspended matter with greater vols. of discharge, but the quantity carried at any given discharge may cover a wide range. During the period July 1–Sept. 21, 1929, the mean content of suspended matter was 7.30% and the mean daily load more than 1,500,000 tons, the mean flow being about 8,000 ft.-sec. On one occasion the suspended-matter content was as high as 40.8%. R. E. THOMPSON

An early chapter in the history of water filtration. CHARLES F. MARSH. *Eng. News-Record* **105,** 609–10(1930).—Interesting data are given regarding what is generally accepted to be the first slow sand filter, installed at the Chelsea Eng. Waterworks Co.'s plant by James Simpson in 1829. The filtration works at Manchester and Glasgow visited by Simpson prior to that date are believed to have consisted of infiltration galleries in gravel and sand adjacent to rivers. R. E. THOMPSON

Difficulties encountered in the operation of Spencer Filtration Plant. TOM CONNEL. W. Va. Univ., *Tech. Bull.* No. **3,** 107–11; *U. S. Pub Health Eng. Abstracts* **10W,** 90 (Sept. 6, 1930).—The plant comprises a circular mixing flume, a circular sedimentation basin, 2 filter units, a small clear well in which the water is chlorinated and a large distributing reservoir equipped for spray aeration. The raw water is collected by impounding the flow from a watershed of $^3/_4$ sq. mile. The water carries a turbidity of 40–1800 p. p. m. and is highly colored. From 3.5 to 7.6 gr. per gal. of alum and 1.9 to 3.5 gr. per gal. of soda ash are used as coagulants. The CO_2 content of the filtered water ranges from 10–35 p. p. m. The effective detention period is about 1 hr. Formerly during hot, dry weather an offensive taste and an odor of H_2S appeared. Prechlorination at the mixing flume at the rate of 1 p. p. m. removed the H_2S taste and odor but not tastes due to algae. C. R. FELLERS

Water softening and purification methods. J. A. MCGARIGLE. *J. Am. Water Works Assoc.* **22,** 1609–24(1930).—Clarification and softening are discussed. The use of mech. agitators with or without added clay is advocated. Vertical steel tanks have advantages over horizontal concrete tanks. The consideration of water softening includes the use of evaporators with or without previous treatment—hot lime-soda treatment, phosphate addns., zeolite softening and various combinations of these 3 methods. D. K. FRENCH

Zeolite water-softening plant installed at Springdale, Pa. J. F. PIERCE. *Eng. News-Record* **105,** 800–2(1930).—The recently completed softening plant at Springdale is described and illustrated. The well water, which has a temporary hardness of 190–368 p. p. m. and a permanent hardness of 0–127 p. p. m., is pumped to an elevated tank, from which it flows under a uniform head to the 2 upward-flow base-exchange softening units, which have a combined capacity of 610,000 gal. per day. The flow is upward during regeneration and washing also, the rate of flow during softening being 6 gal. per sq. ft. per min., and during washing and regeneration 4 to 8 gal. per min. Sufficient hard water is by-passed to adjust the final hardness to 4 grains per gal. The strength of brine employed for regeneration is 6%. Both the length of runs and the wash period are controlled by soap tests. The water is chlorinated prior to distribution. R. E. THOMPSON

Oil burner used in recarbonation of lime-softened water. JAMES A. WORSHAM. *Eng. News-Record* **105,** 649(1930).—The new water supply of Bloomington, Ill., derived from Money Creek, although softer than the water formerly supplied from deep wells, contains about 250 p. p. m. of hardness. The water is softened by the excess-lime method and recarbonated with CO_2 produced in a com. oil burner installed in a low-pressure boiler, which supplies heat and hot water for the offices. The flue gases are diluted with air from 15 to 4% CO_2, scrubbed, compressed and dried, the scrubber consisting of a bed of coke sprayed with water. The oil consumption is 3 quarts per hr. The daily water consumption is about 2 million gal. per day. R. E. THOMPSON

Colloid chemical questions of feed-water treatment with particular consideration of desilicifying. R. STUMPER. *Die Wärme* **53,** 859–62(1930).—Colloids have recently gained importance in boiler operation in consideration of such problems as silicate boiler scale, foaming and corrosion. Foaming and the effect of colloidal material on the origin of precipitates in boilers have been theoretically treated by Langmuir (cf. *C. A.* **22,** 470). The practical application of this work is discussed. Stabilizing of the colloidal state may be of use in the prevention of boiler scale, but it may also bring about foaming. The application of colloidal boiler-scale inhibitors must be tested under operating conditions. The importance of a consideration of silicic acid and the char-

acteristics of silicate boiler-scale formation are discussed. Three processes are suggested for desilicifying: (1) condensation of H_2SiO_3 to colloidal silicic acid, (2) pptn. of H_2SiO_3 as an insol. silicate, and (3) a combined chem. and colloidal process. Through protective action of known colloids, *e. g.*, humus materials, pptn. of scale in the water softener and boiler can be retarded, while pptd. material will be kept in the colloidal state. ALLEN S. SMITH

Of what importance is sodium phosphate in boiler-feed water treatment? HAENDELER. *Die Wärme* **53**, 881–3(1930).—The effect of Na_3PO_4 in feed water is 3-fold. It removes the residual hardness, inhibits corrosion and removes scale previously formed. Well treated feed water will have a residual hardness of 0.25° to 2.0° which is concd. by evapn. With an excess of soda the residual hardness is pptd. as a loose carbonate sludge in boilers operating at pressures under 15 atm. Above that pressure scale is formed, since the high temp. decomposes the soda. Na_3PO_4, in contrast, is stable and forms a difficultly sol. and finely divided alk. earth phosphate. The higher cost of Na_3PO_4 will prohibit its use where cheaper reagents produce an equal residual hardness. The presence of Na_3PO_4 produces a definite protective action against corrosion. The effect of Na_3PO_4 is 500-fold greater than that due to an equal amt. of sulfate and therefore it may be used in smaller concns. The lower salt content will improve the quality of the steam by decreasing foaming and knocking (cf. *C. A.* **23**, 3287). With a small excess of phosphate, scale which has formed is dissolved. The soln. of the scale is a slow base-exchanging process. Analytical methods for the detn. of phosphate offer difficulties. Colorimetric methods are described. The concn. of Na_3PO_4 in boiler-feed water should be maintained at 15 to 30 mg. per l. calcd. as PO_4. ALLEN S. SMITH

Determination of phosphates in presence of silica in boiler water. ELWOOD W. SCARRITT. *Ind. Eng. Chem., Anal. Ed.* **3**, 23(1931).—The presence of silicic acid causes the development of a blue color similar to that produced by H_3PO_4 in the colorimetric detn. with molybdate. By properly adjusting the H-ion concn., however, it is possible to overcome the error, but the tests with the standards must contain the same H-ion concn. Directions are given in detail. W. T. H.

Removal of dissolved gases from boiler water for prevention of corrosion. W. A. S. HARMON. *Petroleum World and Oil Age* **27**, 90–3, 95, 118, 120(1930).—*Deaerators* of boiler H_2O for the reduction of corrosion are of the following types: (1) In the flashtype deaerator, the heated H_2O is admitted to a chamber under vacuum so that the H_2O boils or flashes, throwing off the dissolved gases. This is particularly effective for the removal of NH_3 or H_2S. (2) The heated H_2O is injected into a vessel through which steam at the same temp. as the H_2O is sweeping. (3) The heated H_2O rains over evapg. tubes carrying steam. (4) The H_2O cascades first over a series of heating trays, then over a series of deaerating trays. The steam atm. in the deaerating section is gas-free, hence the films of H_2O continuously give off their dissolved gases to it. A p_H value of 7 is usually taken as representing a neutral H_2O. In severely corrosive waters, securing a p_H value of 9.5 after deaeration will inhibit corrosion. EMMA E. CRANDAL

How a county farm solved its sewage disposal question. R. E. MCDONNELL. *Munic. Sanitation* **2**, 18, 19, 39(1931).—An activated-sludge plant of the mech. aeration type was built at a cost of $30,000 to treat wastes from a population of 2000. The plant produces an effluent that runs for 3 miles through a dry stream bed without causing offense. G. L. KELSO

Origin, operation and economics of the new clarification-pond plant at the military camp at Grafenwohr. W. HUBER. *Gesundh.-Ing.* **52**, 871, 886(1929); *U. S. Pub. Health Eng. Abstracts* **10**, S, 71(July 5, 1930).—A plant of settling tanks and fish ponds, with arrangements for distributing the sewage from a collecting reservoir to both plants, is described. The preclarification tanks of the new plant are on the Dyckerhoff and Widmann system and are in duplicate to meet the requirements of varying flow and possible epidemics. The unit consists of settling tank, septic-sludge tank, tank for the septic water displaced by the sludge and an arrangement for uniting this liquid after digestion with the fresh settled sewage from the settling tank. In case of an epidemic, the effluent can be treated with NaOCl and $Na_2S_2O_3$, though recognized injury to carp and tench in the ponds has been carefully considered. The handling, care and feeding of the fish are described. The revenue for the sale of fish aids in paying the running expenses of the plant. C. R. FELLERS

Calculations for sand traps and clarification tanks. V. MANN. *Wasserkraft Wasserwirtsch.* 1929, 237; *U. S. Pub. Health Eng. Abstracts* **10**, S, 71(July 5, 1930).—The effect of sand traps and clarification tanks depends on the speed of the flow and

also on the speed of settling of the particles. The latter speed increases from zero until it reaches a point when the resistance of the water is equal to the accelerating power of gravity. The time of acceleration is short and, in practice, can be disregarded, and the final speed can be better estd. by practical observations in settling flasks or tanks than by calcn. C. R. FELLERS

Modern clarification plants for town sewage. J. HAUSEN. *Tech. Rundschau, Woch. Berl. Tagebl.* May 1, 1929; *U. S. Pub. Health Eng. Abstracts* **10**, S, 71(July 5, 1930).—Sludge digestion in Emscher or 2-storied sedimentation tanks decrease, with the amt. of sludge, facilitates the dewatering of the sludge and prevents objectionable odors. The amt. of CH_4 which is liberated during sludge digestion and collected in gas reservoirs is greatly increased, and the size of the septic tanks may be decreased by raising the temp. of the sludge to 25°, circulating the sludge and mixing ripe with fresh sludge. The activated-sludge process gives a much greater sepn. of sludge from sewage. The sewage from the Emscher tanks is treated with activated sludge in aeration tanks and then freed from the sludge in secondary clarification tanks. Part of the sludge is returned to the aeration tanks and part is taken to the septic tank, where it is digested with the fresh sludge from the preliminary purification. C. R. FELLERS

Centrifuges for the desiccation of mud in installations for clarifying urban drainage. JUAN PÉREZ. *Quím. e ind.* **7**, 229–31(1930).—Mud may be rapidly removed with the centrifuge and dried in air. Such app. has been installed in Hamburg, Hannover and Frankfort-on-Maine. The process "Ter Meer," which utilizes the centrifuge, gives a product which contains 65% moisture and which is similar to moist humus earth. The effluent used to contain 1–2% of finely divided solid and did not meet conditions usually imposed by river and canal regulations. By modifying the form of the drum of the centrifuge this trouble was overcome. Various working data are given.

S. L. B. ETHERTON

Chemical precipitation of humic pigments. C. P. MOM. *Water and Water Eng.* **32**, 476–7, 526–8(1930); cf. *C. A.* **24**, 3583.—Coagulation of humic matter by means of $Al_2(SO_4)_3$ is effected by simultaneous influence of H ions, Al ions and colloidal Al_2O_3. If a ferric salt is used as a coagulant, coagulation is effected by the simultaneous influence of H ions, ferric ions and colloidal Fe_2O_3. If in these processes free Cl happens to be present, a part of the org. matter is withheld from coagulating by the destructive effect of the Cl on the humus colloids. ALICE W. EPPERSON

Large activated-sludge plant for San Antonio, Tex. H. R. F. HELLAND. *Eng. News-Record* **105**, 886–7(1930).—Since 1901 the sewage of San Antonio has been stored in a 900-acre reservoir (Mitchell's Lake) and used for irrigation. The new 30-million gal. per day activated-sludge plant now under construction, consists of revolving and bar screens, an incinerator for screenings, grit chambers, pre-settling tanks, activation channels of the spiral-flow type, final settling tanks, heated sep. sludge-digestion tanks, sludge lagoons and lab. The settling tanks will be equipped with revolving sludge scrapers. The activation channels are designed for a 5-hour aeration period, at the rate of 1.5 cu. ft. of air under 8 lb. pressure per gal. of sewage, and 20% of returned sludge. The 4 digestion tanks will provide 45 days' storage and will be heated by means of hot-water coils around walls. The gas collected in the domes provided for that purpose will be used to heat water for the coils and to burn the screenings. The effluent will flow to Mitchell's Lake and thence either into the San Antonio and Medina Rivers or to irrigation ditches. The estd. cost of the plant is $900,000, or $30,000 per million gal. per day. The sewage flow is estd. at 75 gal. per capita per day. R. E. T.

Sanitation and potable water for China. A. M. SHAW AND J. A. L. WADDELL. *Far Eastern Rev.* **25**, 396–7(1929).—Water-carriage methods of sewage disposal cannot be employed in China because of the lack of adequate public water supply and the need for conserving all fertilizer material. A simple *digesting cell* is suggested, constructed to yield material of max. fertilizing value. WM. H. ADOLPH

British methods of dealing with river pollution. H. MACLEAN WILSON. *Munic. Sanitation* **1**, 672–6(1930).—Much early legislation on river pollution in England led to complicated and tedious legal methods of conducting sanitary affairs. Since most public water supplies for drinking purposes came from wells or impounding reservoirs, the action to prevent stream pollution was caused by the foul condition of the streams. This condition menaced the health of the people, made stream water unfit for any use and destroyed all fish. Domestic sewage is treated by screening, passing through detritus tanks, aerating and settling. Sludge is digested and dried in earthen lagoons. In general, trade refuse is coagulated and settled and the sludge filtered. G. L. K.

Air filtration. E. T. OLLETT. *Domestic Eng.* **49**, 150–4(1929); *U. S. Pub. Health Eng. Abstracts* **10**, AC, 12(July 12, 1930).—Methods of dust removal are described.

Dry cloth filters are effective when the air velocity is under 20 ft. per min. A water spray is effective in air velocities up to 500 ft. per min., when it removes 95% of dust other than soot and 70% of the soot. An oil film on metal mesh arranged in cells removes 98% of dust: It does not remove fog unless air is dried to drive off water filming each dust particle. Water sprays and oil films may be combined so that the spray removes fog while the film removes soot. For removing industrial dusts, cyclone separators are useful only for large, heavy particles. Settling chambers remove heavy particles over 0.1 mm. diam. if the velocity is under 10 ft. per sec. Particles under 10μ will not settle under any com. conditions. Textile bag filters deal effectively with fine dusts and some smokes. Electrostatic methods of dust settling are described. For general use, the textile bag filter is recommended, provided it is fitted with the automatic, self-scavenging device. C. R. FELLERS

Hygiene of indoor swimming baths, their development and appropriate construction. C. L. P. TRUB. *Veröff. Geb. Medizinalverwaltung* 19, 520(1929); *U. S. Pub. Health Engr. Abstracts* 10, Sw, 7(July 12, 1930) —From personal investigation and questionnaires, T. concludes that the only hygienically satisfactory method is the circulation of the water with disinfection and filtration, combined with daily renewal of the whole of the water. Disinfection with Cl is the most common method used in Germany, but the method of addn. and the amt. required need further investigation. The continued effect of Cl or ozone is preferable to the temporary effect of ultra-violet light, which also requires very complete preclarification. C. R. FELLERS

Greensand bibliography to 1930 with a chapter on zeolite water softeners (SHREVE) **8.** Clarifying device for the waste waters of the cellulose and paper industry (Ger. pat. 512,323) **23.**

Purifying water. FIRMA ROBERT KUNER. Ger. 510,178, Sept. 30, 1926. In purifying water by addn. of soda soln., a satd. soda soln. having a temp. between 40° and 104° is used. Within that temp. range, the soly. of soda varies with the temp. less than at lower temps., and a more accurate regulation of the amt added is accordingly possible.

Purifying water. SOC. GÉNÉRALE D'ÉVAPORATION (PROCÉDÉS PRACHE ET BOUILLON). Fr. 690,559, April 29, 1929. An app. is described for purifying water by bringing it into intimate contact with chem. reagents.

Water filter. ROY B. EVERSON (to Everson Filter Co.). U. S. 1,788,510, Jan. 13. Structural features.

Filter for water, sewage, etc. OSKAR KARV. Ger. 510,088, May 17, 1928.

Base-exchange substances suitable for softening water. SVEIN DAHL-RODE (to Cochrane Corp.). U. S. 1,788,805, Jan. 13. Reaction is effected between iron furnace slag and NaOH (suitably by stirring them with water); after drying the reaction product it is treated for removal of undesired compds. and then subjected to successive washings with hot salt soln., acidulated with HOAc. An arrangement of app. is described. Cf. *C. A.* **24**, 1451.

Base-exchanging substances. GENERAL ZEOLITE CO. Brit. 334,677, July 27, 1929. An alkali metal silicate soln. contg. 0.25–2.0 mols. of silica to each mol. of alkali metal oxide is caused to react with a soln. of amphoteric metal hydroxide contg. 1–2.5 acid equivs. to each equiv. of amphoteric metal oxide. Preferably the conditions are such that a gel embracing all or most of the reacting substances is obtained. The gel is dried, with or without pressing, preferably below 100°, and washed free from sol. salts. Cf. *C. A.* **24**, 909.

Gel zeolites, etc. GENERAL ZEOLITE CO. Brit. 334,676, July 27, 1929. Concd. reacting solns. such as those of Na silicate and Al sulfate are brought into contact in proportioned quantities in a coalescing flow, mixing and reaction being effected during the flow and in a mixing chamber. The mixt. is collected in a suitable tank where the gel is allowed to develop (the process being carried out at ordinary temp.).

Apparatus for separating gases, vapors and oil from boiler-feed water. M. N. LUTZENKO. Russ. 58,337, Nov. 14, 1929. Constructional details.

Electrode system and construction for preventing pitting, corrosion or scale formation in steam boilers, condensers, etc. LEWIS O. GUNDERSON. U. S. 1,788,485, Jan. 13.

Preventing boiler incrustation. ALFRED PFEIFFER. Ger. 510,299, Sept. 22, 1928. The water is brought into contact with a sheet of fabric that has been coated with a paste prepd. by mixing equal parts of tannin and sulfite cellulose lye, and rolled into a spiral.

Removing boiler incrustation. GEORG KROPFHAMMER and ROBERT TOCHTERMANN. Ger. 510,054, July 7, 1925. Dil. acids are used to which albuminous material has been added.

Utilizing waste waters from coal-gas manufacture. HEINRICH BRUNS. Ger. 481,306, May 21, 1925. The waste waters from the treatment of coal gas by the direct ammonia process, especially the condensate obtained from the final cooling of the gases, are treated with NaOH to fix the phenols and then distd. to yield a concd. phenolate lye and water suitable for use as *boiler-feed water*. Preferably, the waste waters are preliminarily concd. by using them for the indirect cooling of the gases. A multiple-effect app. may be used for the distn. Cf. *C. A.* **24**, 5404.

Utilizing industrial waste waters. HEINRICH BRUNS. Ger. 510,056, July 19, 1929. Addn. to 481,306. The method of Ger. 481,306 (preceding abst.) is applied to waste waters obtained in the distn. of lignite, the waters being first freed from tar in the usual way.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER AND M. S. ANDERSON

Advances in agricultural chemistry since the year 1918. A. JACOB. *Z. angew. Chem.* **44**, 1–9(1931). E. H.

Soils of the eastern townships of Quebec. R. R. MCKIBBIN AND L. I. PUGSLEY. MacDonald College, McGill Univ., *Tech. Bull.* No. 6, 3–64(1930).—All soils in this region have a high percent of org. matter concd. in the surface layer. They also have a relatively low Ca and P content and a low nitrate N content throughout the growing seasons. Three main kinds of soil are found: heavily podsolized, brown forest and muck swamp soils. The podsol and brown forest soils have high CaO requirements and a high p_H value. They are also better supplied with Ca, Mg and sesquioxide bases than are the surface soils. The forest crops from a large section of this area should be of great value while the muck swamp tracts should prove highly fertile if they could be drained. J. R. ADAMS

The dispersion and mechanical analysis of certain soils high in sesquioxides. L. T. ALEXANDER. *Soil Research* (*Suppl. to Proc. Intern. Soc. Soil Sci*) **2**, No. 1, 72–6(1930).—Certain lateritic soils high in sesquioxides and of low base-exchange capacity are more readily dispersed for mech. analysis by NaOH than by $Na_2C_2O_4$. With such soils it is recommended that 5 cc. 0.6 *N* NaOH be used as the dispersing agent instead of the usual 10 cc. of 0.5 *N* $Na_2C_2O_4$. I. A. DENISON

Relation between soil humus and climate. HANS JENNY. *Naturwissenschaften* 18, 859–66(1930).—This is a review of the recent work of J. in which math. relationships between the humus content of the soil (N) and temp. or rainfall are derived (cf. *C. A.* **22**, 4702; **23**, 3044; **24**, 2822, 4114). B. J. C. VAN DER HOEVEN

The laws of soil colloidal behavior. III and IV. Isoelectric precipitates. SANTE MATTSON. *Soil Science* **30**, 459–95(1930); **31**, 57–77(1931); cf. *C. A.* **24**, 1695.—Isoelec. ppts. of Al and ferric "hydroxides" are prepd. from the respective chlorides and sulfates by the addn. of NaOH. When NaOH is added to the respective sulfates the isoelec. point is reached at a lower p_H than when chlorides are used. The SO_4 content in terms of equivs. is higher at the isoelec. point than is Cl when the chlorides are used. The ferric complex is isoelec. at a lower p_H than the Al complex. When phosphate and silicate ions enter into the sesquioxide complex the isoelec. point is reached at a lower p_H than when these ions are absent, because they displace diffusible acid anions as well as the hydroxyl ions. When phosphates and silicates are present numerous compns. may be formed. Increasing the quantity of these ions tends to lower the p_H value at which the isoelec. point is reached. In high concns. of these ions, the isoelec. complex approaches but never fully attains satn.; *i. e.*, $P_2O_5/Al_2O_3 = 1$ and $SiO_2/Al_2O_3 = 3$. All the ions in the system mutually displace one another according to the energy of each. At the isoelec. point the dissocn. of anions and cations must be equal. There is a balance between cations and anions in the complex but a stoichiometrical relationship between any 2 ions must be accidental. There is definiteness of compn. within the crystal lattice but not on the surface of the colloids. The data given serve to explain the presence of colloids with high silica and high base content in arid soils, and the removal of these constituents with the consequent increase in sesquioxides under humid conditions. Systems studied include $AlCl_3$ and $FeCl_3$ treated with varying quantities of "Na humate," Na_2SiO_3, H_3PO_4 and bentonite. The humus compd. is prepd. by digesting peat with NH_4OH, allowing it to stand for 2 months, then acidifying the superna-

tant liquid with HCl and electrodialyzing the ppt. 100 g. NaOH is added to 35 g. of the electrodialyzed material to make the "Na humate." The humates differ from the silicates and phosphates in that the colloidal humic complex is quantitatively pptd. by $AlCl_3$ and $FeCl_3$. They show an electropositive max. on the acid side of the isoelec. point and, when the proportion of humus is high, have a second isoelec. point. The ferric "humates" are isoelec. at much lower p_H values than the Al "humates" of corresponding compn. The "humate" ion or ion complex displaces the PO_4 ion and, to a still greater extent, the SiO_3 ion. The PO_4 ion strongly displaces the SiO_3 ion. There is no apparent displacement of the PO_4 ion by the SiO_3 ion, for in the presence of the latter the proportion of P_2O_5 in the complex increases somewhat. This anomaly may be due to the formation of an addn. complex. Mineral soil colloid complexes react with salts of Al and Fe, forming isoelec. ppts. in exactly the same manner as the humus complex. M. S. ANDERSON

Studies on soil acidity, particularly in relation to electrolyte content of soil suspensions. ARNO TERÄSVUORI. *Valtion Maatalouskoetoiminnan Julkaisuja* No. 29, 7–200(1930) (in German).—As a rule, keeping soil samples in dry air does not affect appreciably the acidity or the content of sol. electrolytes in the samples. However, a few exceptions to this rule were found In some cases drying produced an increase and in other cases a decrease of the p_H. The changes were in most cases very small, seldom more than 0.2. When the p_H increased the electrolyte content decreased and *vice versa*. In soil samples rich in ferrous iron or other strongly reducing substances the changes in p_H values produced by drying were sometimes appreciable, particularly when the p_H value in the raw samples was either very low or very high. Warming air-dried mineral soil samples for 3 hrs. at 100–110° resulted generally in a considerable rise in electrolyte content and in lowering of the p_H. In peat soils the changes were smaller. Keeping soil samples at moisture contents of $^1/_3$, $^2/_3$ and full water capacity during varying periods of time (1–4 months) affected the p_H and electrolyte content as follows: In water-satd. soil samples the electrolyte content decreased somewhat and the p_H increased. In samples kept at medium humidity the electrolyte content increased considerably while the p_H decreased. In samples kept at lower humidity the changes were in the same direction as in those kept at medium humidity, but were smaller. In soils low in easily sol. electrolytes additions of acids and salts had a greater effect on p_H value than in soils rich in electrolytes. This must be borne in mind in investigating the buffer strength of soils in relation to acid addns. On investigating the effect of artificial fertilizers on acidity of soils it should be noticed that changes taking place in the p_H of soils cannot serve as a final indication whether acidity has changed and to what extent *E. g.*, a large addn. of superphosphate (1000 kg. per ha.) affects definitely a soil low in electrolytes in reducing the p_H, while it hardly affects the p_H of a soil which is not particularly poor in buffer substances. Extensive tables are given showing results of the investigation. S. L. MADORSKY

Determination of carbonates in soil. C. J. SCHOLLENBERGER. *Soil Science* 30, 307–24(1930).—Application of precautions previously noted (*C. A.* **24**, 4347) as necessary in detg. CO_3^{--} in soil is described, with full description of app. and details of procedure. The method is *applicable to the detn. of* CO_3^{--} *in all kinds of samples*, and suggested modifications for preventing interference by other volatile acids are made. Accuracy, speed and assurance of complete expulsion of CO_2 and its collection in the absorbent are advantages claimed. The app. consists of a 200-cc. round-bottom flask contg. the sample, connected to a similar l. flask for the absorbent by a vertical condenser. The app. is connected and air exhausted. Standard $Ba(OH)_2$ in measured excess is drawn into the absorption flask from a pipet. Dil. HCl, etc., for decompn of the sample is allowed to enter the sample flask. Upon warming the latter, the mixt. boils at a low temp., expelling CO_2 and driving it into the flask contg. the $Ba(OH)_2$ for absorption; this is completed within 8 min. after the CO_3^{--} in the sample is decompd. Excess $Ba(OH)_2$ is titrated in the absorption flask with 0.1 *N* HCl and thymolphthalein in presence of $BaCO_3$, or under some circumstances it may be necessary to collect the latter. E. J. C

The Neubauer method of determining assimilable potash and phosphoric acid anhydride in soils. M. SARTORI. *Atti III congresso naz. chim. pura applicata* 1930, 547.—The Neubauer method is advocated. E. M. SYMMES

The carbonic acid-bicarbonate and water extracts for determining the phosphoric acid requirements of soils. B. DIRKS AND S. SCHEFFER. *Landw. Jahrb.* **71**, 74–99 (1930).—Solvents usually employed for the extn. of available phosphate from the soil have a much lower p_H than the root sera of the plants. For this purpose the authors use a $CaCO_3$ soln. satd. with CO_2 for neutral and alk. soils, and CO_2-free H_2O for acid

soils. The content of a single ext. serves as a measure of a temporary condition; for the total, 4 or 5 extns. are necessary. A single extn. bears a relation to the Neubauer values. Thirty g. of air-dried soil is mixed with 75 cc. of solvent and shaken for 1 hr. The mixt. is then filtered and the H_3PO_4 detd. by the method of Wrangell (*C. A.* **21**, 2752). Before extn. 0.0125% of KCl is added to the CO_2-free H_2O to aid in filtration. A series of tables shows the relation to other methods. D. and S. think the citric acid method not accurate because the p_H is too low. GEORGE R. GREENBANK

Effect of superphosphate on the reaction, base saturation and buffering power of acid mineral soils. LUDWIG SCHMITT. *Das Superphosphat* **6**, 219–27(1930).—A no. of field expts. over a period of years showed that superphosphate behaves in the soil as a physiologically neutral salt and has practically no effect on the reaction, base satn. and buffering power of acid mineral soils. K. D. JACOB

The oxidation of pyrite and sulfur as influenced by lime and magnesia. A 12-year lysimeter study. W. H. MACINTIRE, W. M. SHAW AND J. B. YOUNG. *Soil Science* **30**, 443–57(1930).—Twelve-year lysimeter expts. showed an increase in outgo of sulfate when various forms of lime and magnesia were present Sulfate outgo from $FeSO_4$ addns. was in the order of heavy magnesia, light magnesia, light lime, S material alone and heavy lime. The order of outgo from pyrite was light lime, pyrite alone, heavy lime, light magnesia and heavy magnesia. Complete recoveries of sulfate were obtained from the $FeSO_4$ addns. with CaO and MgO but not from the $FeSO_4$ alone or $FeSO_4$ plus 32 tons of lime. Complete recovery of sulfate equivalences of elemental S were made from the 2 MgO supplements but not from the others. Complete recovery of S was not obtained from any of the 5 pyrite addns. The formation of insol sulfates and the reduction of sulfates are considered as factors responsible for incomplete sulfate recoveries. The total losses of Ca and of Mg from the several addns. were generally in close agreement. The liming treatments effected a decrease in the outgo of K. Some increase in total nitrate outgo was induced by single addns. of liming materials while unsupplemented S materials caused a decrease in nitrate outgo. M. S. ANDERSON

The determination of the plant-assimilable nutrients in soils. M. WRANGELL. *Landw. Jahrb* **71**, 149–69(1930).—To det. the assimilable phosphate content, 1 g. of soil is shaken with 100 cc. of H_2O for 5 hrs. and the suspension centrifuged. The residue is similarly treated with an addnl. 100 cc. of H_2O. The total assimilable phosphate is calcd as $a^2/(a-b)$, where a and b are phosphate contents of the first and second exts., resp. Results agree with the Neubauer values and field trials The method is suitable for detn. of the relative availability of phosphatic fertilizers. A similar process is used for detn. of the assimilable potash in soils, but the exact significance of the results is less clearly defined. In H_2O-culture expts. the use of very dil. solns. corresponding in concn. to soil solns. is preferable to the common introduction of relatively concd. solns. GEORGE R. GREENBANK

Influence of inorganic nitrogen compounds on reaction and replaceable bases of Norfolk sand. R. M. BARNETTE AND J. B. HESTER. *Soil Science* **30**, 431–7(1930).—A study is made of the influence of different carriers of N on the p_H of the deep phase of a Norfolk sand sodded to lawn and golf green grasses. $(NH_4)_2SO_4$ increases acidity and $NaNO_3$ decreases it. NH_4 phosphate causes some increase in acidity but is less effective than $(NH_4)_2SO_4$. A dressing of 3 in. of clay decreases the effect of both NH_4 phosphate and $(NH_4)_2SO_4$ in decreasing the p_H value of the soil. Bivalent cations predominate in this soil. Applications of $(NH_4)_2SO_4$ decrease replaceable bivalent cations more rapidly than the replaceable univalent cations. This decrease is correlated with increase in H-ion concn. and with a decrease in total equivs. of replaceable cations. M. S. ANDERSON

Nitrogen and organic matter in Hawaiian pineapple soils. A. L. DEAN. *Soil Science* **30**, 439–42(1930).—N and org. matter of a large no. of Hawaiian soils are given. These soils are rich in N compared with those from the southern states, and their org. matter contains a higher % of N than is frequent in soils of the temperate zone. The av. C:N ratio is about 7 to 1. M. S. ANDERSON

Variations in soil reaction affect nitrification. P. E. BROWN AND G. V. C. HOUGHLAND. *Proc. Iowa Acad. Sci.* **36**, 93–7(1929).—The data as a whole show very clearly the significant effects of the reaction of the soil on its nitrifying power. Apparently when the differences in p_H are not very great, the influence of greater acidity may be quite large, and where wide variations occur, the reaction of the soil may overshadow the effects of soil treatments. If the treated soils are more acid, nitrification will be reduced and fertilizer treatments which would ordinarily stimulate the process will have no effect. It should be emphasized that the great acidity in the fertilized soils

is not a result of fertilization but a natural variation in soil reaction in such a soil type as the Carrington loam which is closely assocd. with the Clarion loam, a type contg. lime in the subsoil. Measurements of nitrification or the nitrifying power of treated soils should include tests of reaction or H-ion concn. if the results are to be correctly interpreted. If the reaction varies the treatments will probably show no effect. With wide variations and especially high acidity the nitrification process will be reduced in spite of the treatment which, of course, in some cases may reduce the injurious effects of the acidity. Further, it is not impossible that the treatments may entirely overcome acidity effects. This may, of course, be interpreted to mean that the reaction or acidity limits possible beneficial effects from the treatments. W. G. GAESSLER

Studies on methods of measuring the nitrate-assimilating power of soils. RAY A. PENDLETON AND FREDERICK B. SMITH. *Proc. Iowa Acad. Sci.* **36**, 75–8(1929).—The results so far obtained show quite conclusively that soils have a definite nitrate-assimilating power which may be favored by addns. of org. matter. The data also indicate that it may be possible to measure this nitrate-assimilating power and correlate it with other microbiological activities. W. G. GAESSLER

The spontaneous culture method for studying the non-symbiotic nitrogen-fixing bacteria of the soil. R. H. WALKER AND JOHN L. SULLIVAN. *Proc. Iowa Acad. Sci.* **36**, 53–61(1929); cf. *C. A.* **24**, 4883.—From work of a preliminary nature it appears quite probable that the spontaneous culture test may serve as a biol. method for comparing the fertility of soils. Its greatest value will probably be in its use for testing soils for their lime and phosphate needs. Possibly it may serve as a test for a lack of such other constituents as org. matter, K, S or other essential plant food elements. This method has many advantages as it is simple in manipulation, it requires only a comparatively short time to obtain results and, most important of all, it permits of the study of the N-fixing bacteria in their natural habitat and under practically the same environmental conditions to which they are accustomed in the soil in the field. A short bibliography is appended. W. G. GAESSLER

Influence of humus on the fixation of nitrogen: Azotobacter chroöcoccum and Clostridium pastorianum in impure mixture. Conclusions concerning the biochemical action of humus. JULIU VOICU AND ELENA LUNGULESCU. *Bul. soc. chim. Romînia* **12**, 82–9(1930).—The action of humus on *Cl. pastorianum* and *A. chroöcoccum* should be considered as the result of the slowing up of the process of oxidation. The effect is similar to that produced by the lowering of the O tension. The N of humus is in a difficultly oxidizable complex and is always available to the plants. The resistance of humus to oxidation is a result of its interference with the activity of aerobes. RACHEL BROWN

Nitrogen fixation by Rhizobium meliloti and Rhizobium japonicum. G. GORDON POHLMAN. *J. Am. Soc. Agron.* **23**, 22–7(1931).—This paper gives the results of an attempt to clarify the question as to the ability of *Rhizobium* to fix N in the absence of the host plant. The results obtained are largely neg. but it seems probable that certain species of *Rhizobium* may be able to fix appreciable quantities of N if they are cultivated under the proper conditions. J. R. ADAMS

The direct isolation of Rhizobia from soil. O. N. ALLEN AND I. L. BALDWIN. *J. Am. Soc. Agron.* **23**, 28–31(1931).—A yeast ext., mannitol medium, exerts the most selective chemotactic effects on *Rhizobium meliloti* and *Rhizobium trifolii*. Capillary tubes, sealed at 1 end, were autoclaved in a dish of the medium and were then filled with the sterile medium and suspended with the open end down in an aq. suspension of the soil to be examd. Frequently as high as 90% of the colonies on plates poured from tubes suspended for 12 hrs. resembled cultures of *Rhizobia*. J. R. ADAMS

The effect of various treatments on microörganisms in the soil under a five-year rotation. P. E. BROWN AND B. A. TOMLIN. *Proc. Iowa Acad. Sci.* **36**, 79–85(1929).—It seems evident from this work that such normal soil treatments as manuring, liming, the use of rock phosphate, superphosphate and the addn. of crop residues will stimulate bacterial development and such desirable activities as nitrification and non-symbiotic N fixation. The beneficial effects of such treatments on crop yields, as so often and in fact, usually noted may be due, therefore, in part at least to effects on the soil microörganisms and their activities. In some cases the most important effects of certain soil treatments are undoubtedly bacterial. W. G. GAESSLER

Bacterial activity in soils variously treated. P. E. BROWN AND D. I. AQUINO. *Proc. Iowa Acad. Sci.* **36**, 87–91(1929).—The application of manure in normal amts. to soil under a 5 year rotation will bring about large increases in nos. of bacteria and in the ammonifying, nitrifying, N fixing and sulfofying powers of the soil. The addn of vigorous microörganisms or the supplying of food and energy materials by the manure

apparently has a very important and beneficial effect on these groups of organisms. The Carrington loam is known to be benefited materially by addns. of manure, and increased crop yields follow its use. Thus there is a direct correlation between bacterial nos. and the activities of these groups of organisms and the crop-producing power of soil as affected by manuring. W. G. GAESSLER

Methods of counting the number of legume bacteria in the soil. G. GORDON POHLMAN. *J. Am. Soc. Agron.* **23**, 70–7(1931).—Indications are that it is not possible to isolate and count the legume bacteria in soil by the use of N-free media nor does the use of dyes in media give satisfactory results. The Wilson method (*C. A.* **21**, 787) or some modification of it appears to give approx. figures but it is rather lengthy. Results obtained in the study of dye tolerance indicate the possibility of using dyes in media for sepg. various strains of organisms within species. J. R. ADAMS

Influence of exchangeable ions in soil colloids on bacterial activity and plant growth. N. V. JOSHI AND A. N. PURI. *Mem. Dept. Agr. India, Bacteriol. Ser.* **2**, 65–81 (1930).—Ammonifying, nitrifying and N-fixing bacteria are not present in fully unsatd. soil freed from exchangeable bases. Cultures of these bacteria, when introduced in such a soil, did not survive, and plants did not thrive in them. Some evidence was obtained indicating that this effect of fully unsatd. soil is due to the surface-active H-ions present. The bases used to neutralize the unsatd. soil although combined with the mineral complex can serve as nutrient material for both bacteria and plants. Three equivs. of surface-active H ions are recognized in a fully unsatd. soil. Bacterial activity and plant growth are checked in such a soil, but normal growth can be obtained by neutralizing one equiv. of the H. Nitrification, N fixation and plant growth are inhibited in soils having a part or the whole of surface-active H ions free, but ammonification seems to proceed normally in such soils. There is no evidence to show that exchangeable Na ions are directly toxic to plants, their toxicity most probably being due to adverse phys. conditions set up by the exchangeable Na. K. D. JACOB

The agronomic significance of base exchange. W. P. KELLEY. *J. Am. Soc. Agron.* **22**, 977–85(1930).—The president in his annual address before the Am. Soc. of Agron. clarifies the essential features of base exchange and draws a true picture of the importance of this phenomenon. J. R. ADAMS

Present trends and future prospects in fertilizer manufacture. C. L. BURDICK. *Chem. Met. Eng.* **38**, 24–7(1931). E. H.

The influence of aerial fertilizer on plants. E. N. BAZUIRINA AND V. A. CHESNOKOV. *Bull. acad. sci. union rép. soviét. social., Classe sci. phys.-math.* 1930, 513–24.—Aerial fertilizer directly increases the daily productiveness of the photosynthesis but no proportionality can be noticed between the concn. of CO_2, on the one hand, and the energy of the photosynthesis, on the other. The action of the aerial fertilizer upon the daily productiveness of the photosynthesis may vary considerably. *E. g.*, with the onion the percentage of increase of productiveness is proportional to the intensity of the work done by the plant under normal conditions, while with beans, the increase of the CO_2 content in the air only completes the lack of assimilators and its action is in inverse proportion to the work done by the plant under normal conditions. L. JACOVLEFF

An attempt to codify fertilizer experiments for tropical cultivation. F. MAIN. *Rev. botan. appl. agr. trop.* **10**, 641–8, 723–37(1930).—The regulations of the Intern. Commission of the Inst. of Rome are modified so as to be applicable to fertilizer expts. in the hot countries. Reports should all contain details of climate, soil, exptl. plot, nature of fertilizer, plant requirements, variation of the elements, conditions of application and interpretation of results with emphasis on the nature of the fertilizer and the plant requirements. Each section is taken up in some detail and a form for the report is suggested. J. R. ADAMS

Measurement of the drillability of fertilizers. A. L. MEHRING. *Ind. Eng. Chem., Anal. Ed.* **3**, 34–8(1931); cf. *C. A.* **24**, 677.—Directions are outlined for measuring the angle of repose, apparent sp. gr. and av. particle diam. of fertilizers and for substituting these measurements in an equation to get a coeff. of rate of flow. Ways of making practical use of these detns. in the manuf. and use of fertilizers are suggested. A. L. MEHRING

The effect of some nitrogen fertilizers on nitrification. RAY A. PENDLETON, P. E BROWN AND F. B. SMITH. *Proc. Iowa Acad. Sci.* **36**, 99–103(1929).—The results indicate that the addns. of the various fertilizers all increased the nitrate content of the soils. $NaNO_3$ was superior in this respect to all the other fertilizers used. The treatments also stimulated the nitrifying power of the soil, the $NaNO_3$ showing the greatest effect when the soil alone was used in the tests. When $(NH_4)_2SO_4$ was used in the test, the various fertilizers all stimulated nitrification but there were no definite differences

between the various materials. The results were very similar in the test where $(NH_4)_2SO_4$ and $CaCO_3$ were employed. Apparently in the amts. used here all the fertilizers increased nitrification but the effects from the different materials were very similar.
W. G. GAESSLER

The study of urea fertilizer. JEAN BORDAS AND GASTON MATHIEU. *Compt. rend. acad. agr. France* **16**, 904-6(1930).—The transformation of urea into NH_3 is faster when the soil is richer in org. matter. This action is promoted by the addn. of soy-bean urease or ammoniating bacteria and this activation is especially noticeable in the naturally less active soils. Urea-, nitrous- and nitric-N are found to coexist in soils where the hydration of urea is slow. The best results in culture tests have been obtained by using some soy-bean urease or fresh manure in addn. to the urea.
J. R. ADAMS

Influence of potash sources and chlorine content of fertilizers on yield of cotton. J. J. SKINNER. *J. Am. Soc. Agron* **23**, 13-21(1931).—KCl is as good a source of K_2O for cotton as K_2SO_4 but kainite does not show up quite as favorably. The Cl from either KCl or from kainite in the quantity found in mixed fertilizers for cotton will not become an unfavorable factor as it is far below the limit of Cl endurance for cotton in most soils. This limit seems to be about 118 lb. of Cl per acre. When compounding fertilizers, especially from pure chemicals, it would appear advisable not to have the entire source of K_2O and N from KCl and NH_4Cl. The amt. of Cl from such a mixt. applied at the rate of 900 lb./acre supplies an excessive amt. of Cl for the best growth and yield of cotton.
J. R. ADAMS

Cover crops and green fertilizers. MISS J. GALY-CARLES. *Rev. botan. appl. agr trop.* **10**, 683-8(1930).—The cover crops are divided into 2 groups: those that prevent erosion of the soil and those that act as a green fertilizer. A no. of cover plants are described as to source, description and use.
J. R. ADAMS

Fertilizer ammoniation, a step forward in the industry's progress. F. G. KEENEN *Fertilizer Green Book* **12**, No. 1, 16-8(1931).—The com. treatment of superphosphate with anhyd. NH_3 is briefly described and the advantages of ammoniated superphosphate to the fertilizer industry are discussed.
K. D. JACOB

Should a change be made in analytical procedure for evaluating available phosphoric acid content of fertilizer materials? C. C. HOWES AND C. B. JACOBS. *Ind. Eng. Chem., Anal. Ed.* **3**, 70-2(1931).—The citrate soly. of the P_2O_5 in ammoniated superphosphate contg. more than about 2% NH_3 depends on the p_H of the citrate soln., the length of time that the sample is digested in citrate soln. and the wt. of sample for analysis. The last factor is very important because the official method specifies that a 2-g. sample shall be taken for the citrate digestion. Consequently the citrate soly. of the P_2O_5 in a mixed fertilizer contg. ammoniated superphosphate is found to be different from that of the P_2O_5 in the original material and the soly. varies with the proportion of ammoniated superphosphate in the mixt. A plea is made for a change in the official method that will eliminate these discrepancies.
K. D. JACOB

Production of artificial farm manures. F. B. SMITH, W. H. STEVENSON AND P. E. BROWN. Iowa Agr. Expt. Sta., *Research Bull.* **126**, 167-95(1930).—A good grade of well-decomposed manure can be made by composting straw or corn stalks with such chemicals as $CaCO_3$, $(NH_4)_2SO_4$ or superphosphate, provided a sufficient supply of water is added to keep the compost heap moist. Small amts. of sol. N salts greatly hastened the decompn. of straw into manure; similarly mixts. of sol. N compds. with phosphates and $CaCO_3$ acted very beneficially in the ripening process in straw composts. From 800 to 1000 gal. of water per ton of straw gave the optimum moisture content for efficient artificial manure production. Limited aeration is necessary but too much aeration is decidedly detrimental. Inoculation of the compost with fresh manure, cultures of molds or Adco culture speeded up the decompn. process and produced good manures in most cases. Straw directly from the thresher may be mechanically mixed with chemicals, manure or cultures and immediately wetted down into a compost mass. Better results are obtained if the straw is ground up before composting. The decomposing mass is kept well wetted down and mixed up after 2-3 months. The manure is well decomposed in 5-8 months. Cornstalks or grain straw gave very good results when composted with sweet clover in the ratio of 4:1. The N content of the finished manure varied from 1.7 to 2.9%. The pentosan content was considered the best measure of decompn. in artificial manures. The yield of manure (80% H_2O content) from a ton of straw or cornstalks varied widely but averaged 2230 lb.
C. R. F.

Effects of artificial farm manures on soils and crops. F. B. SMITH AND P. E. BROWN. Iowa Agr. Expt. Sta., *Research Bull.* No. **127**, 199-236(1930).—Well-rotted

farm manure was compared to artificial manures composed of straw, sweet clover, red clover, Adco, etc., in lab. greenhouses and, in some cases, field expts. to det. nitrification, CO_2 production, nitrate assimilation and yield. Well-rotted manure had a much greater effect on CO_2 production in sand cultures than did any of the artificial manures, but some of the artificial manures produced as great an influence as did the fresh manure. Nitrate accumulation was depressed equally by the farm and artificial manures when applied at the rate of 7.5 or 15 tons per acre. The straw-clover manure and the sweet clover manure showed a greater nitrifying effect than farm manure. Artificial manures, in general, produced slightly less stimulation of nitrate-assimilating organisms than the well-rotted farm manure, though the differences were slight. Field expts. covering a 4-yr. period with variously prepd. artificial manures as compared with farm manure showed that nitrate assimilation, nitrification, nitrate accumulation and the nos. of molds, bacteria and actinomycetes were very similarly affected by the addns. of the several manures. The proper composting of straw and cellulose residues may permit the production of artificial manures which will give similar effects on bacteriol. conditions in the soil and on crop yields to those occasioned by farm manure. The reduction in nitrate content in the soil following the application of artificial manures is no greater than that resulting from farm manure. No fear need be felt relative to the use of artificial crop residue manures in normal soils. C. R. FELLERS

The rate of decomposition of some artificial manures. FREDERICK B. SMITH. *Proc. Iowa Acad. Sci.* **36**, 69–73(1929).—The data show that the Adco reagent stimulated the production of CO_2 markedly at first and then decreased it to a rate of about the same as that in the untreated culture. The culture treated with the Iowa reagent produced only slightly more CO_2 than the check for the period of 6 weeks but lost a considerable amt. of N in the form of NH_3. Probably less N would have been lost if some $CaSO_4$ or superphosphate had been added in the reagent. W. G. GAESSLER

The action of ammonium sulfate and the saltpeters on the development of the sugar beet and corn when used in nutrient solutions containing certain salts. T. G. DIKKUSSAR. *Landw. Jahrb.* **72**, 80–103(1930).—Sugar beets develop normally in sand when nutrient solns. are used. The actions of $(NH_4)_2SO_4$, of NH_4NO_3, and of the N of the nitrite depend upon the p_H of the solns. The action is the same for the beets and corn. The $(NH_4)_2SO_4$ is similar to the $NaNO_3$ but less efficient than NH_4NO_2 and NH_4NO_3. At p_H 7 and certain concns. of Ca, Mg and K salts $(NH_4)_2SO_4$ is the best source of N. The nitrite and nitrate are less effective. Increased concns. of Ca, Mg and K salts in the nutrient solns increase the action of $(NH_4)_2SO_4$ but have little effect on the action of $NaNO_3$. Decreasing the concn. of Ca, Mg and K below the optimum decreases the action of $(NH_4)_2SO_4$ and increases that of $NaNO_3$. Altering the concn. of the nutrient soln. alters appreciably the action ratio between $(NH_4)_2SO_4$ and $NaNO_3$. The nutrient salts are found to differ in their effect on the infiltration of Ca, Mg and K ions as indicated by an analysis of the ash. GEORGE R. GREENBANK

The effect of lime on nitrification in the Grundy silt loam. R. H. WALKER AND L. G. THOMPSON, JR. *Proc. Iowa Acad. Sci.* **36**, 45–51(1929).—The results show the pronounced effect of lime on the nitrifying power of this soil, and that nitrification is affected much more by lime than by manure or superphosphate. In fact, the nitrifying power was as high in the soils that had received lime alone as it was where lime, manure and superphosphate had been applied. The data contained in tables and graphs indicate quite definitely that the outstanding need for increased nitrification in the Grundy silt loam is sufficient lime to neutralize the acidity. If the nitrifying power of the soil is a measure of fertility then lime is certainly the treatment most needed for better crop growth on this soil. Unless sufficient lime has been added to correct the acidity of this soil the largest effects from the use of manure and com. fertilizers cannot be expected. A short bibliography is appended. W. G. GAESSLER

Effects of the freeze of the winter of 1928-9 on walnut trees. L. RIGOTARD. *Compt.-rend. acad. agr. France* **16**, 939–43(1930).—The injurious effects of the extreme cold on the walnut trees were somewhat alleviated by the addn. of large amts. of fertilizer. Superphosphate, slag and KCl are strongly recommended as sources of P_2O_5 and K_2O. $(NH_4)_2SO_4$ should be used as a source of N in calcareous soils and $NaNO_3$ or $Ca(NO_3)_2$ in acid soils. J. R. ADAMS

Tests with Norway saltpeter and German lime nitrate. C. LARSON AND E. MANELL. *Kgl. Landtbruks-Akad. Handl. Tid.* **69**, 905–40(1930).—German lime nitrate is Ca nitrate contg. about 14.5% nitrate N and 1% NH_3 N. Norway saltpeter is Ca nitrate contg. 12–13% N. The latter is not now produced, but instead there is a product like the German. Both are very deliquescent but very sol. Tests with Norway saltpeter were made to det. its value on grasslands and clover fields, particularly on

mineral soils having an acid reaction. As a top dressing, Norway saltpeter was quite as good as Chile saltpeter. On soils having an acid reaction it was better than Chile saltpeter. No appreciable difference in clover content of the field could be found. Chem. analyses of the crops showed the same Ca and N contents. Badische lime nitrate has been tested widely in Sweden, but for some crops the no. of comparisons is too small. The quantity of Chile saltpeter required to replace 100 kg. of Badische lime nitrate is calcd. by the Mitscherlich formula. With fodder, turnips and oats, lime nitrate is slightly superior; with barley and turnips it is the same; with clover grass it is somewhat less favorable than Chile saltpeter. With sugar beets, Chile saltpeter is decidedly superior, as well as with winter wheat. This differs markedly from tests in other countries. E. M. SYMMES

Insect poisons. XI. The constitution and synthesis of the pyrethrins. H. STAUDINGER, L. RUZICKA AND E. REUSS. *Ann. Acad. Sci. Fennicae* **A29**, No. 17, 8 pp. (1927); cf. *C. A.* **18**, 2135.—Previous work on pyrethrum is summarized. Either the formula proposed by Yamamoto for pyrethronic acid is incorrect or the active poisons differ in Japan and Dalmatia. The spatial arrangement of the mol. is very important in toxicity; the pyrethrin from synthetic *trans*-chrysanthemumic acid has only slight insecticidal activity in comparison with natural pyrethrins. Research is reported on cyclopentenolone derivs., α-methylcyclopentenolone from wood oil being used as a base. The *O-allyl ether*, b_1 87.5°, was prepd. *Methylallylcyclopentanolone* prepd. by reduction (colorless oil $b_{0.8}$ 84-6°) gave an inactive pyrethrin on esterfication with natural chrysanthemumic acid. **XII. The estimation of the pyrethrin content of insect powder.** H. STAUDINGER AND H. HARDER. *Ibid* No. 18, 14 pp.—Increasing the pyrethrin I and II contents of insect powders by plant breeding is suggested. Two methods of analysis are described which it is proposed to use in plant breeding research. *The acid method.*—Ext. pyrethrum with light petroleum ether for 18 hrs. Evap. the solvent in a current of CO_2, removing the final traces *in vacuo*. Ext. the residue (I) several times with CH_3OH, warming each ext., cool and filter. Add water to the filtrate to 10% and place the soln. in a freezing mixt. for 2 hrs., filter and concentrate *in vacuo*. After 8 hrs.' sapon. with alc. NaOH ext. the neutral substances with Et_2O, acidify the soln. with H_2SO_4 and distil the monocarboxylic acid (II) in steam. Titrate the distillate contg. (II) with 0.1 *N* NaOH. Ext. the chrysanthemumdicarboxylic acid (III) from the distn. residue with Et_2O, after clearing with animal charcoal. Distil off the solvent and titrate III with NaOH. Calc. the pyrethrin content from these results. The residue from CH_3OH extn. (I) was analyzed similarly, but the amount of steam-volatile and water-sol acids was insignificant. *Method of estn. by detn. of the crude semicarbazones.*—Treat the CH_3OH ext. with semicarbazide-HCl and CH_3COONa. After 24 hrs. distil the solvent *in vacuo*. Ext. the crude semicarbazones with Et_2O, and shake the soln. several times with H_2O. Distil the Et_2O, det. in the residue by the Kjeldahl method, and calc. the pyrethrin content from this. It appeared that the pyrethrins are the only carbonyl compds. present in the crude oil ext. These methods are useful in detecting adulteration, but the acid anilide deriv. should always be made as a final proof. Analysis of Dalmatian and Swiss samples of pyrethrum indicated that stalks also contain some pyrethrins (0.04–0.1%). Flowers contained 0.4–0.6%. No significant differences in pyrethrin content were found between open, half-open and closed flowers. There appeared to be no correlation between the amts. of pyrethrin I and II in the samples. Alc. should not be used as an extg. agent, since an ester interchange occurs; this effect is more evident with CH_3OH than with C_2H_5OH. If soap is used in the prepn. of an emulsion (for insecticidal purposes) the activity of the pyrethrins will be quickly lost as the simple chrysanthemum esters as well as pyrethrolone have no insecticidal power. Indifferent solvents such as C_6H_6, petroleum ether, $CHCl:CCl_2$ or CH_3COCH_3 should be used for extn. Such exts. can easily be emulsified by the addn. of Turkey-red oil. Cf. also a dissertation by H. Harder, Zurich, 1927. HENRY H. RICHARDSON

A new insecticide against the maize stalk-borer. L. B. RIPLEY AND G. A. HEPBURN. *Farming in S. Africa* **5**, 285–7(1930); cf. *C. A.* **24**, 3597.—Improved derrisol (a soln. of derris in an org. solvent that does not burn the plants) promises to be an excellent insecticide for controlling the corn borer. Although its toxicity is much higher than that of cryolite it has the disadvantage of volatilizing appreciably during hot weather. Preliminary expts. indicate that the best results can be obtained by the use of a suspension of cryolite in derrisol. Natural cryolite is slightly more toxic to the corn borer than synthetic; both materials cause plant burning to about the same extent. Because of its finer state of division synthetic cryolite adheres to foliage better. Resin soap should not be used as an adhesive in insecticides contg. derris, because it

reduces the toxicity of the latter, but gelatinized starch and size gave promising results. K. D. JACOB

The insecticide and anticryptogam treatments of walnut trees. A. PAILLOT. *Compt.-rend. acad. agr. France* **16**, 885–9(1930).—The trees should be treated not later than the middle of June with a mixt. contg 1% of $CuSO_4$, 1% of hydrated lime and some lime or Pb arsenate. The first treatment should be followed by 2 subsequent treatments. Supplementary precautions can be taken, such as exposing the walnuts to SO_2 and treating the trees in the winter with a mineral oil emulsion. J. R. A.

Codling-moth experiments, 1929-30. S. L. ALLMAN. *Agr. Gaz. N. S. Wales* **41**, 834–44(1930).—In general, the results confirmed those obtained during the previous season (N. S. Noble, *C. A.* **25**, 765). K. D. JACOB

Organic mercury compounds for the control of scab and rhizoctonia of potatoes. B. A. BROWN. Conn. (Storrs) Agr. Expt. Sta., *Bull.* **164**, 87–106(1930).—Twelve treatments for the control of scab and 18 for the control of rhizoctonia were tested during a 2-yr. period. Eight of the treatments were new DuPont mercurials 2 were Semesan and 3 Bayer products. $HgCl_2$, CH_2O and no-treatment plots were used for controls. Very few, if any, differences were detected in the germination and vine growth of the several treatments. Corrosive sublimate, 1:960, was clearly the best control for rhizoctonia. Hot CH_2O (1:120) and Bayer Dipdust were about equal in effectiveness but much less effective than the $HgCl_2$. The cold CH_2O treatment commonly recommended for scab prevention was very ineffective. In general, the new mercurials were less effective for the control of potato scab and rhizoctonia than the older prepns. C. R. FELLERS

When to treat quackgrass most effectively with chlorates. H. K. ROWLEY. *J. Am. Soc. Agron.* **23**, 41–2(1931).—Double applications of 10% $NaClO_3$ soln. applied at the rate of 250 gals./acre practically eradicate quackgrass irrespective of the time of application. Applied at this rate it does not prove highly toxic to Kentucky bluegrass. J. R. ADAMS

N developments in 1930 throughout the world (TYLER) **18**. Determination of nicotine in commercial solutions and insecticides (SABATIÉ) **7**. *Azotobacter* (KALANTARIAN, PANOSSIAN) **11C**. Fertilizer. REINHARD GOLDBERG and KARL O. SCHMITT (to I. G. Farbenind. A.-G.). U. S. 1,788,828, Jan. 13. Crude phosphate is decompd. with HNO_3 at least 10% in excess of the quantity required for decompn., K_2SO_4 is added and $CaSO_4$ is sepd. by filtration, and the soln. is at least partly neutralized by an agent such as NH_3 which introduces no inert materials.

Fertilizers. ERNST STREICHER. Ger. 510,097, Feb. 22, 1927. Soft earthy crude phosphates, *e. g.*, Algiers phosphate, are opened up by treatment first in the natural state, and then after grinding, with waste solns. of acid character derived from vegetable materials. Suitable solns. are water expressed from peat, sap from green fodder, waste waters from the distn. of wood and peat and spent tanning liquors. Peat dust and sulfates or chlorides of alkali or alk. earth metals may be added to the phosphates, to accelerate the process.

Fertilizers. CARL EHRENBERG. Ger. 510,925, Feb. 10, 1929. Lime nitrogen is made up into non-dusty, non-corrosive, useful form by mixing with C humus and briquetting under pressure. Cf. *C. A.* **25**, 767.

Fertilizers. NIKODEM CARO and ALBERT FRANK. (Hugo Heimann, inventor). Fr. 689,041, Jan. 28, 1930. A fertilizer is made by submitting humic acids or vegetable materials contg. humic acids or a substance tending to form humic acids such as lignite or peat to a moderate oxidation at a temp. between 50° and 300° by means of air

and afterward passing NH_3 over the products obtained. Other gases such as CO_2 and steam may also be present.

Fertilizers. KALI-CHEMIE A.-G. Fr. 689,351, Feb. 3, 1930. K fertilizers, practically free from Cl and contg. phosphate, are prepd. by decomposing KCl or a mixt. of KCl and NaCl with mineral acids such as H_2SO_4, H_3PO_4 or acid salts of these acids, or HNO_3, and using the HCl produced by the reaction for decomposing phosphates. Cf. *C. A.* 25, 767.

Fertilizers. LOUIS A. GARCHEY and BERTHE GARCHEY (NÉE GODILLOT). Fr. 689,908, Apr. 22, 1929. Powd. substances, particularly fertilizers, are preserved by mixing with them powd. $MgSiO_3$ (talc).

Fertilizers. I. G. FARBENIND. A.-G. Fr. 688,857, Jan. 25, 1930. An easily spread fertilizer is made by projecting a concd. soln. of urea and $Ca(NO_3)_2$ which has been evapd. down to a water content of about 5%.

Fertilizers. LOUIS NOMBLOT and COMPAGNIE MINIÈRE DU M'ZAITA. Fr. 36,761, Apr. 11, 1929. Addn. to 652,427 (*C. A.* 23, 3536). In the process of the prior case the soln., after elimination of the $(NH_4)_2SO_4$, is evapd. to dryness on the water bath without any addn., the HCl in excess being eliminated by evapn. The last traces of HCl are removed by dilg. with water, adding the required amt. of CaO or $CaCO_3$, and evapg. again.

Fertilizers. PATENTVERWERTUNGS AKT.-GES. ALPINA (SOC. ANON. POUR L'EXPLOITATION DE BREVETS ALPINA, PATENTE EXPLOITATION CY ALPINA, LTD.). Fr. 688,617, Jan. 21, 1930. The agglomeration to a hard mass of fertilizers ordinarily occurring in fine grains is prevented by bringing the material into a form having larger grains.

Fertilizers. RUHRCHEMIE A.-G. Fr. 690,117, Feb. 17, 1930. Simple or mixed fertilizer salts which may be preserved or spread at will, particularly salts having a nitrate basis, are made by limiting the amt. of conversion liquid whereby large grains are obtained. The manuf of several fertilizers and details of procedure are given.

Fertilizers. SOC. CHIM. DE LA GRANDE PAROISSE (AZOTE ET PRODUITS CHIM.). Fr. 36,710, Jan. 11, 1929. Addn. to 679.017 (*C. A.* 24, 3599) The double decompn. of $NaNO_3$ with KCl described in the prior case is carried out in the mother liquors themselves.

Fertilizers. SOC. D'ÉTUDES SCIENTIFIQUES ET D'ENTREPRISES INDUSTRIELLES. Fr 691,285, Mar. 6, 1930. NH_4Cl, KCl and a salt of P are made by treating solns. of NaCl and KCl, *e. g.*, solns. of ores such as sylvenite, with phosphoric acid and NH_3, free or combined in the proportion of 1 mol. of acid to 2 of NH_3, sepg. by cooling the P salt formed, and then sepg. the KCl and NH_4Cl either separately or together After sepn. of the P salt the soln. may be boiled and treated with NH_3 in excess to crystallize a salt of the formula $Na(NH_4)_2P_2O_6$ which is sepd along with or before the KCl and NH_4Cl.

Fertilizers. SUCRERIE AGRICOLE DE BOLBEC-NOINTOT. Fr. 691,129, May 10, 1929. Slimy residues from sugar manuf. are made suitable as fertilizers by adding water-absorbing substances such as CaO.

Fertilizers. NAUCHNUI INSTITUT PO UDOBRENIYAM IM. YA. V. SAMOILOV V. S. N. KH. SSSR and I. VOLFKOVICH. Russ. 58,272, Nov. 13, 1929. $CaCN_2$ is decomposed with H_3PO_4 or by a mixt. of H_3PO_4 with other inorg. acids in the presence of sulfates or phosphates of NH_4 or K.

Urea fertilizers. I. G. FARBENIND. A.-G. Fr. 691,245, Mar. 6, 1930. See Brit. 332,948 (*C. A.* 25, 554).

Urea. I. G. FARBENIND. A.-G. Brit. 334,564, April 2, 1929; Fr. 690,090, Feb. 17, 1930. Urea or mixts. contg. it and suitable for use as *fertilizer* are prepd. by heating a carbamate such as that of NH_4 to about 150–250° in the presence of a quantity of NH_3 equal to at least three times that combined with CO_2 in the carbamate and under a partial pressure of the NH_3 higher than the crit. pressure of NH_3. Catalysts such as C, Al or Mg chloride, HCl or H_3PO_4 may be added.

Supplying carbon dioxide to plants. FRIEDRICH RIEDEL. Ger. 512,319, Dec. 4, 1928. Fuel-combustion gases to be supplied to plants are enriched in CO_2 by mixing $CaCO_3$ or other suitable carbonate with the fuel, the proportion of fuel to $CaCO_3$ being higher than that necessary to decomp. the $CaCO_3$. Alternatively, a mixt. of $CaCO_3$ with the amt. of fuel required to decomp. it may be burnt in a shaft kiln, and the excess of fuel may be burnt in an ordinary oven, the combustion products being mixed. The fuel and carbonate mixt. may be briquetted. Addnl. details are given. Cf. *C. A.* 24, 4575.

Insecticide. ARPAD DE WICZWINSZKY. Fr. 689,815, Feb. 13, 1930. Insecticides

are prepd. by the action of pyridine or its salts on pyrethrum or on the active principles of pyrethrum isolated or in soln.

Insecticides. SCHERING-KAHLBAUM A.-G. (Herbert Schotte and Karl Görnitz, inventors). Ger. 510,376, Feb. 11, 1925. Nicotine is mixed with gypsum and the mixt. is hydrated and cast.

Insecticides. SCHERING-KAHLBAUM A.-G. (Herbert Schotte and Karl Görnitz, inventors). Ger. 511,983, Feb. 13, 1925. Addn. to 510,376. The compn. described in Ger. 510,376 (preceding abstr.) is modified by including a superficially active material, *e. g.*, C or silica gel. The nicotine content of the compn. can then be raised.

Insecticides. SCHERING-KAHLBAUM A.-G. (Georg Kirschbaum, inventor). Ger. 510,377, Mar. 15, 1925. Nicotine is mixed with $MgCO_3$ or magnesia usta. The mixt. may be compressed into tablets.

Destroying insects. I. G. FARBENIND. A.-G. Ger. 512,361, Oct. 10, 1928. Use is made of secondary or tertiary amines contg. at least $2C_6H_5$ groups attached to the N atom, or their halogen or alkyl derivs.

Disinfectants for the earth. HANS HAUNSCHILD and JOHANN WIDMANN. Fr. 689,451, Feb. 5, 1930. A disinfectant for the ground contains tar or its distn. products and caustic lime and the lime is slaked by adding water.

Fungicides. SACCHARIN-FABRIK A.-G. VORM. FAHLBERG, LIST & Co. Ger. 510,411, Sept. 17, 1924. Fungicides for dry application to seeds are prepd. by mixing water-insol. Cu compds. with water-sol. cyanomercury compds. $CuCO_3$ 1 and Na cyanomercuricresolate 1 part is a suitable mixt.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

The effect of Steffen waste on the fermentation of pentosans from the corn-stalk. E. I. FULMER, C. H. WERKMAN, R. M. HIXON AND A. L. WILLIAMS. *Proc. Iowa Acad. Sci.* 36, 111(1929).—It was found that Steffen waste furnishes a suitable source of N, salts and buffers for the growth of *Aerobacter pectinovorum* on pentosan material prepd. from corn-stalks. W. G. GAESSLER

Detection of isopropyl alcohol in spirits. K. BODENDORF. *Z. Untersuch. Lebensm.* 59, 616–7(1930); cf. *C. A.* 25, 166.—Distil a mixt. of 5 cc. of the sample with 5 cc. of H_2O from a 50-cc. flask through a condenser tube with a right-angled bend (each arm 20 cm. long). When 5 cc. of the distillate is obtained, mix 2 cc. with 4 cc. of H_2O and 0.2 g. of charcoal, filter and pipet 2 cc. of the filtrate as a layer on 1 cc. of a fresh soln. of *m*-nitrobenzaldehyde in 50 cc. of concd. H_2SO_4. Place the tube in hot water for 1 min.; in the presence of 0.1% of isopropyl alc. a bright ring is observed at the junction of the liquid. If a pale yellow ring is obtained, it is advisable to repeat the charcoal extn., though the sensitivity of the test is thus somewhat lessened. C. R. F.

Nature of the optically active substance precipitated with gypsum in lime defecation of black liquor from regeneration in the tartaric acid industry. FILIPO PERCIABOSCO. *Atti III congressonaz. chim. pura applicata* 1930, 526–8.—The substance looks like gum arabic, is rather insol. in alc., is optically active and contains 56.39% of ash, mainly Fe_2O_3 and phosphates of Al and Ca. It has not been identified. E. M. SYMMES

The regeneration of potassium salts from mother liquors of tartaric acid plants. FILIPPO PERCIABOSCO. *Atti III congresso naz. chim. pura applicata* 1930, 513–9.—It is better to regenerate the K salts from K acid tartrate plants by direct crystn. as KCl and K_2SO_4 than to ppt. them as alum. Figures are given. E. G.-F.

Study of the use of "rapidase" in brewing. M. VERSCHAEVE. *Bull. assoc. élèves inst. sup. fermentations Gand* 31, 319–32, 348–51(1930).—The use of "rapidase" (an amylolytic diastase obtained from cultures of various bacteria, particularly *B. mesentericus*) enables a max. yield to be obtained, irrespective of the grade of malt and proportion of raw grain used, even with insufficiently disintegrated malts. It therefore permits of conducting the malting process in such a manner as to obtain desired characteristics in the finished beer, regardless of the influence such processing may have on the diastatic properties of the malt. Rapidase being chiefly a liquefying agent, its use greatly simplifies the working of raw grains and other malt substitutes. The starchy material is mixed with an equal wt of water and added, together with the rapidase, to a suitable amt. of water previously heated to 80–5°; when operating in this way, liquefaction of the starch is almost instantaneous; the optimum p_H for liquefaction undergoes no change. Rapidase also easily permits of complete recovery of

all the starch from the spent grain by dilg. with water, boiling a few min., cooling to saccharifying temp. and adding the enzyme. A. PAPINEAU-COUTURE

Nitrogen balance in brewery mashes and spent washes. I. Electrolyte precipitation of protein substances in brewery mashes. B. BLEYER AND W. DIEMAIR. *Landw. Jahrb.* 71, 1–16(1930).—Examn. is made of the changes occurring in the nitrogenous matter during the customary processes of prepn. and fermentation of potato mash. The Scherning method for the fractional pptn. of proteins is successfully adapted to the clarification of protein pptn. during steaming, the activity of the proteolytic enzymes during mashing, and the further pptn. and decompn. of the proteins during fermentation. GEORGE R GREENBANK

The first malts of the 1930 season. S. PICKHOLZ. *Brau- und Malzindustrie* 11, 188(1930).—A table is given showing the chem. and phys. analysis of the first malts of 1930 from Austria, Czechoslovakia and Yugoslavia. S. LAWFER

Additional malts of the 1930 season. S. PICKHOLZ. *Brau- und Malzindustrie* 12, 208–9(1930).—Analyses of 1930 malts from Central Europe are given S. L.

Notes on the barleys of 1930. J. RAUX. *Brasserie malterie* 20, 258–69(1930).—A comparison of the compn. and quality of 1929 and 1930 barleys from the standpoint of their suitability for brewing purposes. A. PAPINEAU-COUTURE

Barleys of the 1930 crop. D. KULKA. *Brau- und Malzindustrie* 8, 131–3(1930).—A valuation is given of Austrian and Czechoslovakian barleys of 1930, with a table showing their phys. and chem. analyses. S. LAWFER

Barleys of the 1930 crop. S. PICKHOLZ. *Brau- und Malzindustrie* 9, 149–52 (1930).—Analyses of 1930 barleys from Austria, Czechoslovakia, Hungary and Germany are given. S. LAWFER

Additional barleys of the 1930 crop. S. PICKHOLZ. *Brau- und Malzindustrie* 11, 187–8(1930).—Analyses of 1930 barleys from Central Europe are given. S. L.

Oats of the 1930-31 crop. M. GOETHALS. *Bull assoc. élèves inst. sup. fermentations Gand* 31, 352–9(1930).—A discussion of their brewing qualities, dealing in turn with the products from the various districts of France and comparing them with the previous year's crop. A. PAPINEAU-COUTURE

Iron and copper in white wines. J. RIBÉREAU-GAYON. *Ann. fals.* 23, 535–44 (1930); cf. *C. A.* 24, 1462, 2561.—A study and discussion of the effects of Cu and Fe and the mechanism of their pptn. in wines contg. free SO_2. Even when the wine has been exposed to the atm. for a considerable length of time, most of the Fe is in the ferrous state; on the other hand, there is nearly always a small quantity of Fe^{+++} even when the wine is deprived of O, unless it has stood for a very long time In certain cases, on addn. of Fe all or part of the added Fe^{+++} (not Fe^{++}) is converted into a complex ion which no longer reacts with $K_4Fe(CN)_6$; on standing out of contact with the atm., the complex ion slowly reverts to Fe^{+++}. In the absence of catalysts, there is no appreciable oxidation of SO_2 in the course of 7 days at 15°; there is considerable oxidation in the presence of Fe or Cu, and more in the presence of both, the oxidation increasing with the Cu content. The oxidation of tannin is very slight in the absence of Fe; it is catalyzed by Fe, but not by Cu. In the absence of metallic salts, tannin catalyzes strongly the oxidation of SO_2; in the presence of metallic salts it acts as an antioxygen. On removing increasing amts. of Fe (by adding $K_4Fe(CN)_6$ and filtering) the oxidizability decreases, very sharply at first because the Cu is removed first, and then progressively till it becomes nil for a few days; on standing longer the dissolved O content decreases slightly. On again adding Fe the oxidizability increases according to the amt. of Fe added, but does not recover its initial oxidizability even with high Fe contents. The initial oxidizability is restored by adding the original amts. of Fe and Cu. Cu has a higher catalytic power than Fe. A. PAPINEAU-COUTURE

Determination of potash and alkalies in wines and musts. LUCIEN SEMICHON, MICHEL FLANZY AND (MISS) LAMAZOU-BETBEDER. *Ann. fals.* 23, 517–26(1930).—The principle of the method consists in destroying org. matter with HNO_3 with Hg as catalyst, and detg. K_2O as $KClO_4$. The following technic has been worked out and is recommended: evap. 50 cc. to sirupy consistency in a 200-cc., round-bottomed Pyrex flask (evapn. may even be carried to caramelization, or to partial carbonization, but should preferably be stopped when sirupy consistency is reached), add 25 cc. concd. HNO_3 and 2 drops Hg, evap. to 1 cc. If the soln. blackens showing incomplete destruction of org. matter, repeat the addn. of HNO_3 and evapn. till the org. matter is completely destroyed. Add 10 cc. boiling water to the hot soln., add excess of satd. $Ba(OH)_2$ soln. (about 5–10 cc.), boil, ppt. $Ba(OH)_2$ by passing a current of CO_2 for 2 min., boil 2 min., pass a moderate current of H_2S for 30 sec., boil off the excess of H_2S, wash into a 100-cc. volumetric flask, cool, make up to vol., filter. To 50 cc. of filtrate in a 75-cc. evapg.

dish add a few drops of 1 + 2$HClO_4$, evap. to 10 cc. on the water bath, add 10 cc. of 1 + 2$HClO_4$, evap. on the water bath, heat carefully on a sand bath until the excess of $HClO_4$ is evapd., let cool, wash with 15, 2, 2, 2 and 2 cc. 96% alc. contg. 0.2% $HClO_4$, triturating each time and decanting through a filter, dissolve the $KClO_4$ in boiling water, add a little $HClO_4$, evap. first on the water bath and then on the sand bath as before, wash with alc as before, transfer to a tared Gooch crucible, heat at 125–30° to const. wt. and weigh. The remaining alkalies can be detd. in the alc. filtrate by adding H_2SO_4 and igniting to sulfates, the amt. of alk.-earths being negligible. Na can be detd. *via* Blanchetière (*C. A.* **17**, 3006). The work carried out in developing the method is described, giving data justifying the various steps of the technic. It is shown more particularly that the methods based on the detn. of K bitartrate give very unreliable results; they should be completely discarded, total tartaric being detd. by the Kling and Lassieur method (*C. A.* **4**, 1590; **6**, 3382) and total K_2O by the above method. A. PAPINEAU-COUTURE

The influence of leavens on the attenuation of beer. J. RAUX. *Brasserie & malterie* **20**, 228–36, 246–53(1930).—An address. A. PAPINEAU-COUTURE

Acidity and the bacteriological stability of beer. MARC H. VAN LAER. *Bull. assoc. élèves inst. sup. fermentations Gand* **32**, 20–7(1931).—An address. A. P.-C.

Pilsen beers. J. RAUX. *Brasserie & malterie* **20**, 309–15(1931).—A discussion of the manuf. of Pilsen beers and of the factors giving them their characteristic properties. A. PAPINEAU-COUTURE

A study of pasteurization (of beer). M. EPSTEIN. *Bull. assoc. élèves inst. sup. fermentations Gand* **31**, 360–5(1930).—A beer having the following compn., apparent solids 3.081, true solids 4.851, solids of original wort 13.722, alc. 3.54, total N 0.406, apparent attenuation 77.55, true attentuation 64.65, p_H 4 5, was divided into several lots, which were pasteurized successively at monthly intervals. Beers pasteurized after keeping at least 12–13 weeks kept well after pasteurization. The nature of the glass and the corks used may also have considerable effect on the success of pasteurization. The results obtained by pasteurizing beer contg. colupulin were about the same, but it did not keep as long as that contg. no colupulin. Beer made with distd. water and from grain from which the bran had been sepd remained clear over 6 weeks after pasteurizing; when the bran was not sepd. from the grain, the beer became turbid a few days after pasteurizing. This is attributed to pptn. of SiO_2. When tap water or dil. NaCl soln. was used instead of distd. water, there was little or no difference in the keeping qualities after pasteurizing, with or without presence of bran. Addn. of 1.5 g. "tausul" (found to contain 25% tannin and 60% $KHSO_3$) per hl. pptd. about 35% of the total N, irrespective of the p_H of the beer. A. PAPINEAU-COUTURE

Measuring the surface tension of beer and worts. J. DE CLERCK. *Bull. assoc. étudiants école sup. brasserie univ. Louvain* **30**, 136–50(1930).—The Traube stalagmometer method is studied in detail. The instrument has been modified by placing the capillary above and in a straight line with the graduated pipet, to which it is connected by a ground-glass joint; in addn., there is provided an auxiliary T-tube connected to the top of the capillary by rubber tubing, the purpose of which is to regulate the rate of flow of the liquid from the pipet. The latter is filled by connecting one tube of the T to a suction pump and sucking up the liquid in the pipet; the cock is then closed, the other tube of the T is immersed in water, the 2nd cock is opened; the rate of flow from the pipet decreases as the water rises in the leg of the T-tube, and when the desired rate of flow is reached the T-tube is raised from the water and the flow continues at the same rate. According to King (*C. A.* **19**, 2680) the limiting rate required to obtain the static surface tension is 1 drop in 5 min.; as this is not practical, de C. recommends a rate of about 10 drops per min., the important point being to have always exactly the same rate of flow. Instead of counting the no. of drops from the calibrated portion of the pipet, it is simpler to weigh a given no. of drops, at least 25 and preferably 50 The chief precautions to be observed are: scrupulous cleanliness of the instrument, and especially of the flow nozzle; avoidance of formation of bubbles at the flow nozzle and vibrations; operation always at the same temp. A. PAPINEAU-COUTURE

Surface tension and the part it plays in brewing. J. DE CLERCK. *Bull. assoc. étudiants école sup. brasserie univ. Louvain* **30**, 127–36(1930).—The theory of surface tension is briefly explained, and the part played in brewing by surface tension at the free surface of the liquid, surface tension at the walls of the containers and surface tension around the dispersed phases present in worts and beer is discussed. A. P.-C.

The growth of yeast and increase of its components in large-scale production. H. CLAASSEN. *Biochem. Z.* **228**, 154–62(1930).—The increase in the dry substance, protein, N-free material and ash was followed in fermentation expts. The protein

formation was greatest at the time when there was available (in the wort) sugar and easily assimilable N, especially NH_3 N. The increase in non-nitrogenous components of the yeast was greatest toward the end of the fermentation when there was no sugar, but amino acids, alc. and N-free org. acids. Addn. of NH_2N does not increase the total mass of yeast, but the yeast becomes richer in protein and contains less N-free substance. S. MORGULIS

Effect of pure culture inoculation on the quality and chemical composition of sauerkraut (PEDERSON) 12. Asphaltic bitumen and its use in breweries (Aerts) 20. Multistage evaporating apparatus [in cellulosic fermentation] (Brit. pat. 334,623) 1. Sucrose from impure solutions containing invert sugar (U. S. pat. 1,788,628) 28.

Rectifying alcohol. SOC. ANON. DES DISTILLERIES DES DEUX-SÈVRES. Fr. 689,914, Apr. 23, 1929. Very pure alc. is obtained directly from fermented worts, wines or weak alc. solns. by submitting the liquids to a purification before the distn. of the alc., to remove all the heavy impurities or fusel oils and a part of the volatile impurities, and afterward distg. the alc. and concg. it at the same time by eliminating the remainder of the volatile impurities. The first purification is carried out on a liquid titrating at most a few degrees Gay-Lussac; only a part of the liquid is vaporized and treated while avoiding all concn. of the alc. A suitable app. is described.

Butyl alcohol and acetone. HUGO WERTHEIM and WALTER POLLAK. Fr. 690,395, Feb. 21, 1930. BuOH and acetone are prepd. by fermentation of worts contg. carbohydrates by means of bacteria of the species *B. amylobacter* A. M. and Bredemann which have been habituated by cultivation to increasing amts. of acid. Fr. 690,396 describes the prepn. of BuOH and acetone by fermentation in which the carbohydrate mashes of the main fermentation are acidulated from the beginning by the addn. or fermentative generation of non-volatile org. acids, preferably lactic acid.

Butylacetonic fermentation. DAVID A. LEGG (to Commercial Solvents Corp.). U. S. reissue 17,930, Jan. 13. Reissue of original pat. No. 1,668,814 (*C. A.* **22**, 2235).

Citric acid. ARTHUR M. PEAKE (to Commercial Solvents Corp.). U. S. 1,788,739, Jan. 13. Enzymes of citrous fruits such as those of lemon pith are added (apart from their essential oils) to solns. or suspensions of pectinous materials such as apple pulp or "wood dextrins" and a catalyst such as Mn sulfate or Ti salts.

Apparatus for drying and roasting malt. SOC. ANON. DES ANCIENS ÉTABLISSEMENTS SKODA À PLZEN and RUDOLF SCHLENK. Fr. 689,030, Jan. 28, 1930.

Wine. RÉNÉ TROTTIER and HIPPOLYTE LUQUET. Fr. 690,616, May 6, 1929. An app. consisting of a series of connected vats is described for the continuous fermentation of wort for the production of wine.

Rectification of wine. SOC. DES ÉTABLISSEMENTS BARBET. Fr. 36,954, Feb. 26, 1929. Addn. to 664,585 (*C. A.* **24**, 915). The double rectification of the prior case is applied to the existing plant whether of the direct or indirect type.

Yeast. DISTILLERS CO., LTD., and E. A. MEYER. Brit. 334,502, May 1, 1929; Fr. 689,238, Feb. 1, 1930. In a continuous process of yeast manuf. (as from a nutrient soln. formed with molasses) with continuous addn. of nutrients and continuous withdrawal of yeast-contg. liquid, growth of undesirable organisms is inhibited without detrimental action on the yeast by continuous addn. of substances such as Cl, Br, I, pyridine or nicotine or other alkaloids which are, as used, non-toxic to yeast but which have a bactericidal action. Bleaching powder may be used.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Evaluation of chenopodium oil. KURT BODENDORF. *Apoth. Ztg.* **45**, 1636–8 (1930).—From the author's own expts. and methods proposed by other investigators it would appear that the development of an exact quant. method based upon iodometric procedure is highly improbable. W. O. E.

1-Hydroxy- and 1-aminoalkyl derivatives of theobromine. C. A. ROJAHN AND HEINZ FEGELER. *Arch. Pharm.* **268**, 567–72(1930).—The present study was undertaken to discover if possible certain derivs. of theobromine suitable for subcutaneous or intravenous injection. Among the compds. prepd. and characterized were the following: *1-hydroxyethyltheobromine* (I) (by heating in sealed tube at 125° theobromine, NaOH soln. and $HOCH_2CH_2Cl$), $C_9H_{12}O_3N_4$, m. 193°, gave with PCl_5 *1-chloroethyl-*

theobromine, $C_9H_{11}O_2N_4Cl$, m. 152°, the latter in turn yielding with Et_2NH *1-diethylaminoethyltheobromine* (*picrate*, $C_{19}H_{24}O_9N_8$, yellow warty crystals, m. 155–6°), and with $PhNH_2$ *1-p-phenylaminoethyltheobromine*, $C_{15}H_{17}O_2N_5$, m. 171°. Similarly, *1-p-ethoxyphenylaminoethyltheobromine*, $C_{17}H_{21}O_3N_5$, m. 156°. The *acetate* of I m. 139°, the *benzoate* m. 151°, the *phenylurethan* m. 125°. *1-β-hydroxypropyltheobromine*, $C_{10}H_{14}O_3N_4$ (from the Na or Ag deriv. of theobromine in xylene suspension with β-chloropropanol in a tube at 110° to 120°) m. 129° (*acetate*, $C_{12}H_{16}O_4N_4$, leaflets, m. 112°; *benzoate*, $C_{17}H_{18}O_4N_4$, m. 162°; *phenylurethan*, $C_{17}H_{19}O_4N_5$, m. 175–6°); *1-β-chloropropyltheobromine* (*picrate*, yellow warty masses, m. 179–81°); *dimethylaminopropyltheobromine* (*picrate*, $C_{18}H_{22}O_9N_8$, m. 250°). W. O. E.

Examination of spiritus saponatus and spiritus saponis kalini D. A.-B.VI. WALTER MEYER. *Arch. Pharm.* **268**, 572–85(1930).—A study has been made of these prepns. with a view to their improvement and their methods of evaluation. W. O. E.

Examination and evaluation of chlorophyll and its preparations. URSULA DREHMANN. *Arch. Pharm.* **268**, 585–9(1930).—A discussion and study (by means of the analytical quartz lamp) of chlorophyll and its more important com. prepns. (notably chlorosan), the results obtained being presented in tabulated form. W. O. E.

Estimation of the alkaloidal content of Extractum belladonnae siccum cum Rad. liquirit. paratum 1 + 1. G. BÜMMING. *Arch. Pharm.* **268**, 590–2(1930).—The results obtained in the examn. of various control samples of this official Ger. prepn. are recorded. W. O. E.

Constituents of a previously unknown drug (Patrisia acuminata). K. W. MERZ. *Arch. Pharm.* **268**, 592–3(1930).—The examn of a small sample of the root showed it to be relatively highly toxic, the m. l. d. for a 20 g. mouse being 0.005 g. of the crude drug. Among other substances thus far isolated from the alc. ext. was a brittle glassy hygroscopic material 40 times more toxic than the crude, but of as yet undetd. compn. Further study is contemplated. W. O. E.

Seasonal variations in the alkaloidal content of Indian Ephedra species. T. P. GHOSH AND S. KRISHNA. *Arch. Pharm.* **268**, 636–41(1930).—The present study shows *E. nebrodensis* possesses the highest, and *E. intermedia* the lowest, alkaloidal content. *E. intermedia* from Chini Range, Bashahr Division, Punjab, contains a high % of pseudoephedrine (1.8%) and can therefore serve as raw material for the production of this alkaloid. The highest content of ephedrine, namely, 1.93%, was obtained from *E. nebrodensis* collected in October in Lahoul. The Indian *Ephedra* species show no rise in alkaloidal content corresponding with the altitude of their occurrence. The alkaloidal content of *Ephedra* growing in moist places is low, and indeed lowest during the rainy season and highest in the fall. *Ephedra* should be collected in October immediately before the advent of frost, dried in the sun and stored in dry places entirely free from moisture. Et_2O dild. with $CHCl_3$ can safely be used in the investigation of the drug without fear of converting the ephedrine into its HCl salt. W. O. E.

Influence of habitat and time of collection of the rhizome of male fern. LUDWIG KOFLER AND ERHARD MÜLLER. *Arch. Pharm.* **268**, 644–52(1930).—The generally prevailing impression in the literature that root collected in the upland is superior to that from the lowland and that the fall product is superior to that gathered in the spring has been tested anew. Of 22 different upland and lowland samples, in which the ext. and filicin contents were detd. and a biol. test was carried out on fishes, no effect of the habitat on the value of the root was apparent. Six samples collected in the spring had chem. and biol. values like those of similar samples gathered in the fall. Of the aforesaid 22 samples only 3 met the requirements of the Ger. Pharm. with respect to ext. and filicin content. This result would indicate a too stringent pharmacopœial standard. Six old samples selected for comparison showed by their action on fish a markedly lower potency than that of fresh stock, although the filicin content was fairly const. It would appear then that the rhizome of male fern deteriorates with age, as indicated by the behavior toward fish rather than by its filicin content. W. O. E.

Application of ethyl *p*-hydroxybenzoate in maintenance of sterility, in sterilization and in disinfection. TH. SABALITSCHKA. *Arch. Pharm.* **268**, 653–73(1930).—An address. W. O. E.

Estimation of morphine in aqueous solutions. H. BAGGESGAARD-RASMUSSEN AND SVEND AAGE SCHOU. *Arch. Pharm.* **268**, 673–80(1930).—The method suggested involves extn. of the relatively concd. (to 20 cc.) morphine soln, treatment with $NaHCO_3$ and Na_2CO_3, with an $CHCl_3$ + iso-PrOH mixt. (3 to 1), and subsequent titration of the recovered alkaloid, after addn. of 0.1 *N* HCl in excess, with 0.1 *N* borax soln. in the presence of methyl red soln. (2 drops) and methylene blue soln. (1 drop). It is

necessary to carry out the extn. with reasonable expedition. The method is inapplicable to sirups of low morphine content. W. O. E.

New method for estimating nicotine in oriental tobacco. JAMES BURMANN. *Helv. Chim. Acta* **13**, 785–7(1930).—The essential features of the method are: Moisture detn. is effected by drying 10 g. of the sample in an air bath at 100° to const. wt. For the nicotine detn. weigh out in a porcelain capsule (10 cm. diam.) 3 g. of the dry sample, add little by little 3 cc. 30% NaOH (or KOH) soln., stirring the mixt. several min. with a glass rod (note evolution of NH_3). Add 3 g. plaster of Paris, stirring several min., during which time the mass should become powdery and dry. Introduce this powder into a 150-cc. flask closed with a rubber stopper carrying a 3-way glass stopcock, evacuated by the aid of a water pump, discharge the vacuum, add 75 cc. pure Et_2O, agitating the mixt. from time to time over a period of an hr. After the liquid is allowed to stand a further hr. or two, pass it through a folded filter. Transfer 50 cc. of the Et_2O soln. (= $^2/_3$ of the sample) to a 150 cc. Erlenmeyer flask, evapg. the solvent by heating on a steam bath at 50° Repeat this operation 3 times with 5-cc. portions of abs. Et_2O for complete elimination of all traces of NH_3. To the residue add 20 cc. pure Et_2O, 50 cc. distd. neutral H_2O (p_H 7), evap the Et_2O on a steam bath, cool and add 1 drop of a 1% bromocresol purple in alc., then titrate with 0.1 *N* HCl, comparing the end point with a standard (50 cc. H_2O + 1 drop of indicator and 1 drop of 0.1 *N* HCl). The percentage of nicotine = no. of cc. 0.1 *N* HCl × 0.081. W. O. E.

Effect of sunlight on ephedrine solutions. EDMOND E. MOORE AND MARJORIE B. MOORE. *Ind. Eng. Chem.* **23**, 21–3(1931).—Solns of ephedrine alkaloid were found to be unstable in sunlight. O is essential for this decompn. Benzalephedrine is one of the chief decompn. products of the aq. soln. Ephedrine carbonate has been isolated and its properties have been detd. W. O. E.

Leonurus cardiaca L. B. PATER. *Pharm. Monatshefte* **11**, 154–6(1930).—The ash of this plant was found to contain: SiO_2 10.5, Cl 1.5, Fe_2O_3 + Al_2O_3 2.1, CaO 22.0, MgO 8.9, P_2O_5 20.3, SO_3 2.9, K_2O 13.2, Na_2O 18.2%, I in traces. The plant contained in addn. saponin and a minute quantity of essential oil. W. O. E.

Increasing importance of adsorptive disinfection. ERICH HERRMANN. *Pharm. Presse* (July) **35**, 100–2(1930).—The exptl. work of Bechhold and co-workers, as also the results of clinical experience, has shown the superiority of mineralized adsorbents over those until recently in common use. Adsorgan and silargel may be successfully applied in all cases of stomach and intestinal affections involving chem. and infectious diseases, more particularly in intoxications and autointoxications. The mineralized adsorbents operate prophylactically in inhibiting intestinal infectious disorders as dysentery, cholera, paratyphoid, etc. W. O. E.

Essential oil content of camomile flowers. MAX BERGMANN. *Pharm. Zentralhalle* **71**, 785–9(1930).—A series of expts. is described tending to the improvement of the present official method for detg. the oil, now only in part recovered under the present procedure. The main improvement suggested involves a notable increase in the vol. of distillate. W. O. E.

Raw material and finished product in pharmaceutical practice. K. H. BAUER *Pharm. Zentralhalle* **71**, 801–9(1930).—An address. W. O. E.

Infusion of ipecacuanha root. H. STEUDEL. *Pharm. Ztg.* **75**, 1450–1(1930).—A discussion is made of the official method of prepn. and the alkaloidal content of such prepns. as usually found in the apothecary, in connection with suggestions for improvement in quality. A low alkaloidal content may be due, among other things, to the varying quality of the crude drug, its fineness, method of filtration, etc. W. O. E.

What is novacyl? E. DINSLAGE AND B. STEMPEL. *Pharm. Ztg.* **75**, 1478–9(1930).—Recent examn. of this product showed it to consist of acetylsalicylic acid 64.4, Mg acetosalicylate 29.7 and MgO 5.86%. According to Gehe's Codex novacyl consists essentially of H_2O-sol. Mg acetosalicylate. W. O. E.

Detection of artificial honey in oxymel scillae. H. ABB. *Pharm. Ztg.* **75**, 1479 (1930).—The results obtained in various authentic and control samples would seem to indicate that there is at present no certain method for detecting artificial honey in oxymel scillae. W. O. E.

Sterile solutions in hospital practice. HANS TRUNKEL. *Pharm. Ztg.* **75**, 1499 (1930).—Comments are made on the character and type of glass containers used, notably those of Jena or similar compn., in connection with their resp. stoppers. W. O. E.

New drugs and specialties during the 3rd quarter of 1930. F. ZERNIK. *Süddeutsche Apoth.-Ztg.* **70**, 692–4(1930).—A commentary on certain novelties. W. O. E.

Refracto-densimetric investigation of certain official tinctures. F. WRATSCHKO

AND JOSEFINE KOWARZ. *Pharm. Presse* **35**, 97–9, 115–22, 131–5, 146–51(1930).—The purpose of the present investigation was to det. whether the refracto-densimetric method is capable of yielding values nearly equiv. to those obtained by the direct estn. of the alc. and ext. content. The importance of such a procedure would be particularly striking in the evaluation of mixts. like camphor spirit. A series of tinctures has been examd. and the results obtained were tabulated and otherwise graphically represented. The ext. material chiefly affects the refractive index; the alc. content, on the other hand, chiefly effects the d. For practical purposes it would appear that the new phys. procedure possesses about the same accuracy as the more commonly used dry-residue method. W. O. E.

Etrats. RAPP. *Süddeutsche Apoth.-Ztg.* **71**, 35–6(1931).—This new type of drug, its manner of prepn. and its advantages over the older type of exts. are discussed. Etrats are obtained by exhaustion of the suitably powd. crude drug with a series of solvents (alc., H_2O, glycerol, MeAc, etc.), and subsequent distribution of exts. thus obtained over and in the exhausted marc. Etrats are offered in dry powder form as well as granulated condition. W. O. E.

Black draught. WM. PARTRIDGE. *Analyst* **56**, 29(1931).—*Mistura Sennae Composita* is an article subject to change in every edition of the Brit. Pharm. A table showing the sp. gr., total solids and ash of 11 samples bought in 1930 show that there is something wrong in the "Schedule of Standards" of the Local Government Board of Ireland. W. T. H.

The determination of citronellol and rhodinol in presence of geraniol and nerol. L. S. GLICHITCH AND Y. R. NAVES. *Parfums de France* **8**, 326–33(1930).—From a brief crit. review of the various methods proposed to date, it is concluded that the hot formylation method is the best one available at the present time; but as the results published by different investigators indicate that the various technics give considerable differences in the results, a study was made of the various factors involved in order to obtain as accurate results as possible. The results of the investigation (which are given in detail) led to recommending the following technic: mix the sample with 2 vols. of 90% formic acid (d_{15}^{15} 1.2088) in an acetylation flask connected to a reflux condenser, heat 1 hr. on a boiling water bath shaking every 5 min., let cool, ext. successively in a separatory funnel with 2 × 50 cc. H_2O contg. 10% NaCl, 2 × 50 cc. H_2O contg. 10% NaCl and 2% Na_2CO_3 and 25 cc. distd. H_2O, dry over anhyd. Na_2SO_4, and det. the sapon. no., using 30 cc. 0.5 *N* KOH for 2 g. of the acetylation product with products high in citronellol and rhodinol and 20 cc. with oil of geranium, roses, etc., boiling 45 min. in all cases. Application of this technic to the analysis of several 100 samples of oil of geranium of known purity gave the following limits for the citronellol content: French oils 36–43.8%, Algerian oils 26–40% (exceptionally up to 43%), Réunion oils 44–52% (exceptionally 41–55%). The following are given as very exceptional results obtained on one French and 2 Algerian oils distd. by G. and N.'s firm: d_{15} 0.8923, 0.8929, 0.9009; α —11°14′, —11°24′, —8°25′; n_{20} 1.4637, 1.4645, 1.4688; acid no. 1.12, 3.64, 6.86; esters (as tiglates) 28.46, 24.78, 27.58; total alcs. by acetylation 73.48, 67.33, 70.14; free alcs. 54.90, 51.17, 52.14; apparent rhodinol 58.14, 59.33, 18.85; soly. in 65% alc. sol. in 2.8 vol. with pptn. of paraffin above 12 vol., sol. in 5.5 vol. with turbidity above 7.5 vol., sol. in 5.5 vol. with turbidity above 6 vol.; soly. in 68% alc. sol. in 2.5 vol. with pptn. of paraffins above 10.5 vol., sol. in 3 or more vol., sol. in 3 or more vol. It is shown that Tiemann and Schmidt's method (*Ber.* 29, 922–5 (1896)), consisting in detg. citronellol and rhodinol by means of PCl_3 and geraniol by difference, is inaccurate. The max. error in the detn. of citronellol and rhodinol by hot formylation, when carried out by the technic described above, is 2%, irrespective of the amt. present in the sample analyzed. A. PAPINEAU-COUTURE

Oil of verbena. ÉTABLISSEMENTS ANTOINE CHIRIS. *Parfums de France* **8**, 334 (1930).—The consts. of oil of *Verbena triphylla* l'Hérit. are: d_{15} 0.890–0.912 (exceptionally up to 0.920), α_D —10° to —18°, n_{20} 1.482–1.488, citral (via bisulfite) 26–38% (generally 32–38%), sol. in 1–6 vol. of 80% alc. with occasional turbidity on diln. which persists even in the 90%-alc.-soly. test. Examples are given of exceptional compn. of oils of known purity: (1) n 1.4810, with normal citral content; (2) n 1.4793; (3) citral 39%, α —10°49′, n 1.4810, sol. in 0.5 or more vol. of 80% alc. The compn. of C.'s Algerian oils is generally fairly close to that of the oils of Southern France: they are generally lighter (mostly 0.893–0.900) having higher α (without exceeding the max. of —18°), are lower in citral (generally 25–32%, but falling as low as 20%), have a much lower soly. (about 20 vol. of 80% alc. and 0.5–8 vol. of 85% alc.), and have a slightly lower alc. content. A. PAPINEAU-COUTURE

Oil of myrtle. Établissements Antoine Chiris. *Parfums de France* **8**, 334–5 (1930).—Oils of known origin and purity were recently encountered having consts. outside the generally accepted limits. Corsican oils having otherwise normal consts. had high alc. contents, the Ac nos. of 2 samples being 50.4 and 53.2, instead of 30–38% given by Gildemeister and Hoffmann. An oil distd. in Algeria had: d_{15} 0.9185 (0.881–0.887), α_D^{18} 25°38′, n_D^{20} 1.4702 (1.464), Ac no. 75.5 (39.2), ester no. 28 (17–20.6), esters 9.8%, total alcs. 21.58%, free alcs. 13.88%, sol. in 9.5 and more vol. of 80% alc. and in 0.8 and more vol. of 85% alc. (the figures in brackets are the generally accepted consts. for Algerian oils); the compn. of this oil is similar to that of Syrian oils. The characteristics of Sicilian oils are similar to those of Corsican oils, but with lower d_{15} (*e. g.*, 0.879, 0.8836, 0.8833), higher ester no. (42.7, 55.6, 59.5 instead of 13–25) and higher Ac no. (83.3, 95.2, 101.15, instead of 30–38); alcs. detd. by cold acetylation are practically the same as by cold formylation, showing the presence of little or no tertiary alc. A. Papineau-Couture

Oil of ylang-ylang. Établissements Antoine Chiris. *Parfums de France* **8**, 350–60(1930) (in French and English.)—A review of production and of the properties of the oils of different origins. A. Papineau-Couture

Assay of pharmacopeial sodium hypophosphite. Maurice François and (Mlle.) Laure Seguin. *J. pharm. chim* [8], **11**, 193–7(1930).—See *C. A.* **24**, 3605. S. W.

Assay of alcoholic solutions of nitroglycerin. H. Caron and D. Raquet. *J. pharm. chim.* [8], **12**, 109–18(1930); cf. *C. A.* **24**, 4584, and Richmond, *C. A.* **14**, 2987.—Sapon. methods give irregular results. In the absence of free HNO_3 in the sample the following rapid but only approx. *colorimetric* method may be used: To 0.1 cc. of the 1% trinitrin soln. (*A*) add 1 cc. of the reagent (concd. H_2SO_4 + 10% PhOH or salicylic acid (cf. *C. A.* **5**, 1380)). Mix, then add 10 cc. H_2O, 10 cc. NH_4OH and compare the yellow color with that obtained from a definite quantity of KNO_3. The following *reduction* method is simple and accurate: Put into a Schloesing distg. flask 10 cc. of *A*, 2–3 g. of powd. Devarda's alloy (*C. A.* **2**, 3347), 100 cc. H_2O and 25 cc. of soap lye; when evolution of H is nearly ended, distil the NH_3 formed into 20 cc. 0.1 *N* H_2SO_4 and titrate back with 0.1 *N* NaOH, with Na alizarin-sulfonate as indicator (cf. Mestrezat, *C. A.* **14**, 2291; Fleury, *C. A.* **18**, 1625). Each cc. 0.1 *N* H_2SO_4 consumed indicates 0.00757 g. nitroglycerin. Results by this method are slightly lower than those by the gravimetric method (U. S P.); probably the com. product contains traces of mono- or dinitrin, or perhaps also oxidation products of glycerol. S. Waldbott

Chrysophanic acid, chrysarobin and sulfur. R. Huerre. *J. pharm. chim* [8], **12**, 145–9(1930).—Chrysophanic acid (*A*) was omitted from the French Codex Supplement 1920, in favor of the lower-priced chrysarobin (*B*) ("purified araroba"); *A* and *B* were believed to be equal in therapeutic value (cf. Léger, *C. A.* **7**, 866; **9**, 1972). However, Hesse (cf. *C. A.* **11**, 2328) concluded that only *B*, an anthranol, is effective in dermatology, while *A*, an anthraquinone, has no action. Since recent therapeutically active com. samples are claimed to be *A* and are proposed to be used in pills for which *B* would be dangerous, H. devised the following method to distinguish sharply between *A* and *B*. Put into a test tube or capsule 0.25–0.30 g. of *A* or *B*, 0.10 g. of S and heat the mixt. on a sand bath until (at 180°) H_2S gas is given off. With *B* the resulting mass is green, and after cooling it dissolves almost completely in $CHCl_3$ with an intensely green color If *A* is used, the mass is dark brown, and the soln. in $CHCl_3$ is an intense yellow brown. In mixts. of *B* with *A* (1:1 or 1:3) the color is intensely green, and this color is still visible with a mixt. of 15:85. Extn. of com. *B* with 1% KOH yields upon addn. of H_2SO_4 to the filtered soln. a yellowish brown mass which upon fusion with S gives the test for *A*, confirming Hesse (2 to 8% *A*). S. Waldbott

Chemical and physiological assays of aconite preparations. A. Malmanche *Thesis* (Paris) 1929; *J. pharm. chim.* [8], **12**, 476–8(1930); cf. *C. A.* **23**, 3774.—From sep. studies of the root, the tincture, alcoholature and ext., M. concludes that no concordance exists between results of the chem. and physiol. assays, because of the fact that the proportions of aconitine and allied bases in aconite are variable. It is important to ascertain the value of the crude drug regardless of its geographical origin. Both the flowering and the lateral tubercles have qualitatively the same activity. Proper desiccation of the root does not reduce its activity. The chem. assay should be supplemented by a very simple physiol. test on the guinea pig; this test is sensitive and gives uniform results. The tincture of aconite with p_H 5 is quite permanent for 1 yr. In drugs of the same origin, the alkaloids of the leaves or roots and in the tinctures are identical. The Codex strength of the alcoholature of the leaves should be raised to 0.20–0.25 per 1000. The present Codex formula (1908) for ext. of aconite root should be replaced by demanding evapn. *in vacuo* and at low temp., because prolonged heat

partly transforms aconitine into inert substances. Of the galenical prepns. of aconite root the tincture alone will give reliable therapeutic results provided the chem. assay is supplemented by physiol. titration. S. WALDBOTT

Analytical studies on protargol; determination of alkalinity and silver content. (MME.) ADÈLE LISSIEVICI DRAGENESCO AND (MME.) EUGÉNIE WEINBERG-SACHETTI. *J. pharm. chim.* [8], **12**, 536–9(1930).—To det. alky. in com. protargol (*A*), dissolve 0.25 g. in 50 cc. H_2O, which forms a dark yellow, often brown soln. difficult to titrate. However, when 1 g. of neutral $Na_2S_2O_3$ is added (cf. Daniel, *C. A.* **21**, 2626), the brown color turns to yellow. Add 1 cc. of phenolphthalein soln. (*B*), which produces dark red. At the same time prep. a check soln. without addn. of *B* and titrate the soln. contg. *B* with 0.1 *N* H_2SO_4 until the red color has disappeared and the fluid has the same tint as the standard. Two samples of *A* required 0.567–0.60 cc. of the acid, 2 samples of Ag proteinate 0.89–0.90 and 1.98–1.994 cc. Irritation produced at times in the application of *A* is possibly caused by too high an alky. The Ag content of *A* (8% required) is detd. by titrating with 0.1 *N* NH_4CNS after destroying the org. matter either by calcination at low heat, or by means of $KMnO_4$ and H_2SO_4; the latter method seems preferable. S. WALDBOTT

Synthetic drugs. I. G. FARBENIND. A.-G. (Max Bockmühl and Gustav Ehrhart, inventors). Ger. 510,304, Mar. 26, 1926. Mol. compds. having pronounced analgesic properties are prepd. by fusing 4-dimethylamino-1-phenyl-2,3-dimethyl-5-pyrazolone with trialkylacetamides, or by bringing these components together in soln. Examples are given.

Synthetic drugs. I. G. FARBENIND. A.-G. (Karl Streitwolf, Alfred Fehrle and Walter Herrmann, inventors). Ger. 510,437, Nov. 8, 1928. Benzimidazolonestibinic acids are prepd. by treating *o*-diaminobenzenestibinic acids with $COCl_2$. Examples

are given. The products are useful in treating diseases caused by protozoa. Cf. *C. A.* **25**, 559.

Synthetic drugs. I. G. FARBENIND. A.-G. (Karl Streitwolf, Alfred Fehrle and Walter Herrmann, inventors). Ger. 511,738, Nov. 8, 1928. Addn. to 510,437 (preceding abstr.). Benzimidazolonestibinic acids are prepd. by the action of antimonous acid on the diazo compds. from aminobenzimidazolones. Examples are given.

Synthetic drugs. I. G. FARBENIND. A.-G. (Hans Schmidt, inventor). Ger. 510,440, Dec. 6, 1928. Carbamylarylstibinic acids are prepd. by the reaction of antimony oxide or hydroxide with diazo compds. from 4-carbamylaniline or its nuclear substitution products. An example is given. The salts of the products are useful for treating beri-beri and like diseases.

Synthetic drugs. I. G. FARBENIND. A.-G. (Werner Schmidt, inventor). Ger. 510,449, June 1, 1927. 6-Hydroxybenzylamino-3-arsonic acid and its acyl derivs. are prepd. by condensing *p*-hydroxyphenylarsonic acid in acid soln. with methylol amides, *e. g.*, methylolbenzamide, or methylolphthalimide, and sapong. the acyl derivs. if desired. Examples are given.

Synthetic drugs. I. G. FARBENIND. A.-G. (Karl Streitwolf, Alfred Fehrle and Hubert Oesterlin, inventors). Ger. 510,451, Sept. 4, 1928. See Brit. 318,491 (*C. A.* **24**, 2241).

Synthetic drugs. I. G. FARBENIND. A.-G. (Fritz Schönhöfer, inventor). Ger. 512,406, June 18, 1927. Addn. to 499,826, (*C. A.* **24**, 4521). The prepn. of synthetic drugs from *N*-substituted aromatic aminohydroxy and diamino compds. or their derivs., and nuclear substituted products, described in 499,826, is extended to include compds. in which the aromatic amino groups are replaced by basic hydroaromatic or heterocyclic residues. Thus, the compd. *N*-β-1-piperidylethyl-*m*-phenylenediamine obtained by the action of piperidylethyl chloride on *m*-nitroaniline, is reduced with Fe and AcOH. The compd. b 158–60°. Other examples are given.

Synthetic drugs. SCHERING-KAHLBAUM A.-G (Curt Räth, inventor). Ger. 506,425, May 12, 1927. 2-Hydroxypyridines substituted in the 3- and (or) 5-positions with halogen are converted into water-sol compds., having a better therapeutic action than the initial materials, by treatment with alkylating agents, *e. g.*, alkyl halides, or carboxyalkylating agents, *e. g.*, halo fatty acids, preferably in the presence of an acid-binding substance. Thus, 2-hydroxy-5-iodopyridine, heated on the water bath in alc. KOH soln. with MeI, yields *N-methyl-2-keto-5-iodo-1,2-dihydropyridine*, m. 73–4°. 2-Hydroxy-5-bromopyridine, treated similarly with ClCH$_2$COOH, yields *2-keto-5-bromo-1,2-dihydropyridine-N acetic acid*, m. 237–8°. The prepn. of *3,5-dibromo*, m. 240–41°, *3,5-diiodo*, decompg. 244°, and *3-bromo-5-iodo-1,2-dihydro-2-ketopyridine-N-acetic acid*, m. 244–45°, is described. Cf. *C. A.* **25**, 381.

Synthetic drugs. SCHERING-KAHLBAUM A.-G. Ger. 510,066, June 19, 1926 Addn. to 481,392 (*C. A.* **23**, 4950). The method of 481,392 for producing colorless products by fusing 4-dimethylamino-1-phenyl 2,3-dimethyl-5-pyrazolone with dialkylbarbituric acid, is modified by replacing the latter component by other cyclic ureides, ureas or urethans. Examples are given.

Therapeutically active preparations. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 140,867, Apr. 11, 1928. The method of 128,855 (*C. A.* **23**, 2785) and 139,324 (*C. A.* **25**, 776) for grinding up female and male secretory organs when these are congealed by low temps., is extended to animal products generally which contain hormones, such as hypophysis, cardiac or splenic tissue, bone marrow, blood, etc. Cf. *C. A.* **24**, 4120.

Azo dyes suitable for use as therapeutic agents against germ infections. IWAN OSTROMISLENSKY (to Ostro Research Laboratories, Inc.). U. S. 1,785,327, Dec. 16. A product suitable for use as a therapeutic agent or as a germicide and coloring agent in foods may be prepd., *e. g.*, by diazotizing *p*-phenetidine, coupling with *m*-phenylene diamine, and purifying the product, and, in general, products of similar properties may be obtained by diazotizing an alkoxyaniline, coupling with a *m*-diaminobenzene and purifying, *e. g.*, by effecting pptn. from MeOH soln. by cooling on ice. The description covers generally products of the formula (*p*-ROC$_6$H$_4$N:N)C$_6$H$_3$(NH$_2$)$_2$-2,4, where R may be H or C$_n$H$_{2n+1}$, *n* being less than nine, and the benzene nuclei are free from acidic substituents.

Basic phenol alkyl ethers. HANS HAHL (to Winthrop Chemical Co.). U. S. 1,787,519, Jan. 6. Pharmaceutical products which are basic phenol alkyl ethers are obtainable by reacting upon a compd. of the general formula *o*-YC$_6$H$_4$ORX, wherein R represents an alkylene radical contg. at least 2 C atoms, X stands for a halogen, Y stands for an unsatd. aliphatic residue, such as the allyl, crotyl or propenyl group

and wherein the benzene nucleus may be substituted with an alkoxy group, with a primary aliphatic amine such as ethylamine, propylamine, isobutylamine, as well as unsatd. aliphatic amines, such as allylamine and the like. Details are given of the production of the monoethylaminoethyl ether of 6-allyl-2-methoxyphenol, b_{18} 159–61°, and of the corresponding monoallylaminoethyl ether, b_{10} 170–4°. These products form cryst. salts with acids such as HCl.

Alkylaminoalkyl ethers of phenols. I. G. FARBENIND. A.-G. (Hans Hahl, inventor). Ger. 510,450, Jan. 26, 1928. Addn. to 433,182 and 446,606. Phenols having an unsatd. substituent in the *o*-position to the OH group (other than derivs. of *N*-acyl aminophenols) are treated with an alkylene dihalide in the presence of alkali, and the products are condensed with monoalkylamines. Thus, 2-methoxy-6-allylphenol may react with $(CH_2)_3Br_2$, yielding 2-methoxy-6-allylphenol γ-bromopropyl ether, which is then condensed with NH_2Et to yield the corresponding γ-ethylaminopropyl ether, b_2 142–143°. Other examples are given also. The *products are therapeutically useful.*

Esters of 2-penten-4-ol. I. G. FARBENIND. A.-G. (Karl Boettcher, inventor). Ger. 512,232, Feb. 28, 1925. The hydrohalide esters of 2-penten-4-ol are prepd. by interaction of the strong acid and the alc. at atm. temp. Examples are given. *4-Chloro-2-pentene*, b_{12-13} 18–20°; *4-bromo-2-pentene*, b_8 22°; *4-iodo-2-pentene*, b_9 35–40°. The products are *intermediates for drugs.*

Cyclohexenealdehyde derivatives. SOC. ANON. M. NAEF & CIE. Swiss 139,986 to 139,988, Apr. 17, 1928. Addns. to 136,907 (*C. A.* **24**, 4306). A mixt. of 4,6-dimethyl-Δ^3-cyclohexenealdehyde is produced by condensing isoprene with crotonaldehyde by heating. The end product b. 71–4° at 12 mm. (136,907). 2,2,6-Trimethyl-Δ -cyclohexenealdehyde, b_{12} 79–81°, is produced by heating 1,1-dimethylbutadiene with crotonaldehyde (139,987), and 3,4,6-trimethyl-Δ^3-cyclohexenealdehyde-2, b. 80–81° at 12 mm., is produced by heating 2,3-dimethylbutadiene with crotonaldehyde. The substances are useful as *perfumes* or starting materials for the *manuf. of perfumes.* Cf. *C. A.* **24**, 2243.

Piperidine derivatives. CARL MANNICH. Ger. 510,184, June 3, 1927. Esters of 2,6-dimethyl-4-ketopiperidine-3,5-dicarboxylic acid and its homologs are prepd. by condensing esters of acetonedicarboxylic acid with AcH and NH_3 or primary alkyl- or aralkylamines or their salts. Thus, a dil. alc. soln. of diethyl acetonedicarboxylate, AcH and $CH_3NH_2.HCl$, left for 24 hrs. in the cold, yields *diethyl 1,2,6-trimethyl-4-ketopiperidine-3,5-dicarboxylate*, the nitrate of which m. 123–124°. Other examples are given describing the prepn. of *dimethyl 1,2,6-trimethyl-4-ketopiperidine-3,5-dicarboxylate*, m. 75–76°, (nitrate m. 136°); *dimethyl 1-benzyl-2,6-dimethyl-4-ketopiperidine-3,5-dicarboxylate* m. 97–98°, (nitrate m. 130–133°); and *dimethyl 1-β-phenylethyl-2,6-dimethyl-4-ketopiperidine-3,5-dicarboxylate-HCl*, m. 122–124°. The products are *intermediates for drugs.*

Piperidine derivatives (local anesthetics). SAMUEL M. MCELVAIN. U. S. 1,784,903, Dec. 16. Piperidine derivs. of the general formula

$$\text{CHY.CHY.CHY.CHY.CHY.N}(CH_2)_x\text{OCOR}$$

in which R is an aromatic radical, *x* is an integer, and Y in one place is an aliphatic group and in each of the four other places is a H atom are produced by first causing a reaction of a halogen-substituted alc. with one of the following two substances: (*a*) a substituted piperidine in which a C-linked H of piperidine has been replaced by an alkyl group, and (*b*) a benzoylating agent; and subsequently causing a reaction of the other of such two substances with the result of the first reaction. Details are given of the production of γ-(2-methylpiperidyl)propyl benzoate-HCl, m. 167–9°; γ-(2-propylpiperidyl)propyl benzoate-HCl, m. 184–6°; γ-(3-methylpiperidyl)propyl benzoate-HCl, m. 178–80°; β-(3-methylpiperidyl)ethyl benzoate-HCl, m. 134–6°; γ-(3-carbethoxypiperidyl)propyl benzoate-HCl, m. 161–3°; γ-(3 methylpiperidyl)propyl *p*-aminobenzoate-HCl, m. 158–60°, and the corresponding nitro compd., m. 190–2°; and γ-(3-carbethoxypiperidyl)propyl *p*-aminobenzoate-HCl, m. 110–12°, and the corresponding nitro compd., m. 177–9°. Mention is also made of the production of various isomeric analog of these compds. The products are of sufficiently low toxicity and sufficiently low irritating properties to be suitable for clinical use.

Basic nitro derivatives of 9-aminoacridine. HEINRICH JENSCH and OTTO EISLEB (to Winthrop Chemical Co.). U. S. 1,782,727, Nov. 25. Therapeutically active basic nitro derivs. of 9-aminoacridine, such as 2-β-diethylaminoethoxy-6-nitro-9-aminoacridine (a red cryst. powder, m. 237–8°, and forming a dihydrochloride with 3 mols. of H_2O of crystn. readily sol. in water) are formed by causing compds. of the formula

RNH_2 in which R stands for H or alkyl to act upon nitroacridines substituted in the 9-position by halogen and substituted at another C atom of the acridine ring by a radical contg. at least one aliphatically bound N atom. Examples are also given of the production of 2-β-diethylaminoethoxy-6-nitro-9-isoamylaminoacridine, 2-β-piperidylethoxy-6-nitro-9-aminoacridine, 4-β-diethylaminoethoxy-6-nitro-9-aminoacridine, 2-β-diethylaminoethyl-6-nitro-9-aminoacridine and 2-γ-diethylaminopropoxy-6-nitro-9-aminoacridine and properties of these compds. and their hydrochlorides are given. Cf. *C. A.* **24**, 4521.

Alkali metal salts of the dimercury derivative of bromofluorescein. WILLARD L. VOGEL (one-tenth to Paul W. Prutzman). U. S. 1,789,204, Jan. 13. By reaction in MeOH of 1 mol. proportion of bromodihydroxymercurifluorescein (details of production of which are given) with 4 mol. proportions of caustic alkali such as NaOH, salts are obtained such as the tetra-Na salt which are powerful and non-irritating local antiseptics and preventives of infection.

2,6-Dihydroxy-4,5-dihydropyrimidine acetic acid (dihydrouracylacetic acid). LEO BRODMANN. Swiss 141,019, Mar. 20, 1928. Diethyl hydroxymethylenesuccinate is condensed with urea, hydrogenated and sapond. The *substance* m. 247–250° and *is used in medicine.*

Thymol acetylsalicylate. SCHERING-KAHLBAUM A.-G. (Albrecht Thiele, inventor). Ger. 510,448, Apr. 1, 1927. An alkali thymolate is treated with acetylsalicyl chloride in an indifferent org. solvent. An example is given. The *product*, m. 72–74°, *is therapeutically useful.*

α-Ethyl-α-isopropyl-α-bromoacetamide. GUSTAV HILDEBRANDT, ERWIN LEUBE AND WILHELM BIEHLER (to Knoll A.-G., Chemische Fabriken). U. S. 1,780,131, Oct. 28. This compd., m. 51°, possesses hypnotic and sedative properties, is much less toxic than the corresponding propyl compd., and may be made by (*a*) brominating ethylisopropylacetamide; (*b*) treating ethylisopropylbromoacetic acid ester with NH_3; (*c*) splitting off water from, or dehydrating, NH_4 ethylisopropylbromoacetate; or (*d*) brominating ethylisopropylacetonitrile and subsequently saponifying the bromo compd. to obtain the amide. Various details of manuf. are given.

Stabilizing and purifying chloroform. V. M. KULIKOV. Russ. 60,716, Dec. 20, 1929. $(CH_2)N_4$ or other ammonia-aldehyde compds. are added to $CHCl_3$.

Antipyrine. GOSUDARSTVENNUII INSTITUT PRIKLADNOI KHIMII (GOVERNMENT INSTITUTE FOR APPLIED CHEMISTRY). Russ. 25,925, Mar. 31, 1928; 32,202 Aug. 24, 1928. 1-Phenyl-3-methyl-5-pyrazolone is heated with MeBr.

Preparing codeine. AKTZ. O-VA PROISVODSTVA I TORGOVLI KHIMIKO-FARMATZEVTICHESKIMI PREPARATAMI I MEDITZINSKIM IMUSHCHESTVOM "POSMEDTORGPROM." Russ. 18,224, July 18, 1927. Morphine is acted upon by $PhMe_2NOH$, and the $PhNMe_2$ formed is distd. off with steam after acidification of the reacting mixt. with lactic, formic, tartaric or oxalic acid. The codeine is then sepd. from the residue by usual methods.

Purifying cephalin. R. A. KONOVALOVA. Russ. 51,926, July 27, 1929. A soln. of a salt of crude cephalin is added gradually to a soln. of NH_3 and ether under agitation. The cephalin is then crystallized out from ether by usual methods.

Lecithin preparations. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 510,186, Dec. 28, 1926. See Swiss 136,239 (*C. A.* **24**, 4358).

Alkaloids. BYK-GULDENWERKE CHEMISCHE FABRIK A.-G. Ger. 510,185, May 21, 1926. Raw materials contg. alkaloids are extd. with dil. acid, and the ext. is then purified by careful treatment with NaOH, after addn. of a buffer compd. to assist in keeping the H-iôn concn. at that most favorable for pptg. the impurities. Examples are given. The extn. of conessine in this way is disclaimed.

Oxidation products of porphyrins. HANS FISCHER (Alfred Treibs, inventor). Ger. 510,434, May 28, 1927. Yellow oxidation products termed xanthoporphinogen compds. are prepd. by treating porphyrins in AcOH-$CHCl_3$ soln. with PbO_2. The *products are* reducible to porphyrins, and are *of therapeutic value.*

Emulsions. THE GOLDSCHMIDT A.-G. Fr. 690,330, Feb. 20, 1930. Esters of polyhydric alcs. with satd. or unsatd. higher fatty acids, still contg. free OH groups or derivs. of such esters are emulsified with water or aq. solns. in the presence of acylalkyldiamines or their derivs. Thus, a good "*cold cream*" is made from glycerol-monostearic acid ester 18, white wax 1, white petrolatum 6, suint 4, paraffin oil 7, sweet almond oil 5, glycerol 3, water 55.5 and diethylaminoethyl oleylphosphate 0.5%.

Perfumes. DEUTSCHE HYDRIERWERKE A.-G. Ger. 505,814, June 24, 1926. Perfume-bearing substances are dissolved or fixed by treatment with esters of dicarboxylic acids arising from the oxidation of partly hydrogenated naphthalene with a

completely hydrogenated ring, or hydronaphthol and hydronaphthone. Thus, 2-decahydronaphthol is treated with HNO_3 and NH_4 vanadate to give cyclohexanediacetic acid (I); the di-Et and diisobutyl esters of I are also mentioned.

Perfumes. I. G. FARBENIND. A.-G. Fr. 689,063, Jan. 20, 1930. Perfume mixts. are made with the use of $C_6H_{11}CH_2CH_2CHXCHO$ (X = alkyl) or their ring substitution products. Several examples are given.

The reconstruction of sulfuric and nitric acid mixtures. ALVARO-ALBERTO. *Ann. acad. brasil. sci.* **2**, No. 3, 113–29(1930).—A mathematical discussion and application of formulas for the detn. of H_2SO_4 and HNO_3 contents of mixts., such as could be applied to the revivifying of commercial mixed acids by oleum. J. M. L.

Cottrell process for sulfuric acid recovery. P. E. LANDOLT. *Petroleum Mech. Eng.* **1930**, 98–102.—A review and bibliography is given of the Cottrell app. in acid concn., sludge-acid recovery, vacuum concn., acid gas scrubbing and mist and dust removal. Costs are shown. E. M. SYMMES

Utilization of liquid oxygen obtained as a by-product in the manufacture of synthetic ammonia. M. SUKHAREVSKII. *J. Chem. Ind.* (Moscow) **6**, 1671–4(1929).—In connection with the proposed development of the synthetic NH_3 industry in Russia, the possible utilization of the O_2 obtained as a by-product is discussed. Liquid O_2 is superior to gaseous O_2 from the viewpoint of storage, transportation and utility. Liquid O_2 can be evaporated readily where O_2 gas is needed. The liquid form can be used in blasting explosives. It is now used extensively in France and the United States for this purpose. D. K.

Production of ammoniated phosphate and double superphosphate. PIETRO LEONE. *Atti III congresso naz. chim. pura applicata* **1930**, 486–95.—$2Ca_3(PO_4)_2 + 6H_2SO_4 = 6CaSO_4 + 4H_3PO_4$, $Ca_3(PO_4)_2 + 4H_3PO_4 = 3Ca(H_2PO_4)_2$. These reactions give a product having advantages over the usual mixt. $Ca(H_2PO_4)_2 + 2CaSO_4$. The reactions $Ca_3(PO_4)_2 + 3H_2SO_4 + 4NH_3 = 3CaSO_4$ (sludge) $+ 2(NH_4)_2HPO_4$, and $Ca_3(PO_4)_2 + 4H_2SO_4 + 4NH_3 = [2CaSO_4 + Ca(H_2PO_4)_2 + 2(NH_4)_2SO_4]$ are discussed. E. M. SYMMES

Calcium arsenate and its applications. PABLO HOPE Y HOPE. *Rev. quím.* **6**, 5–14 (1930); cf *C. A.* **24**, 5942. E. M. SYMMES

The hydrates of calcium sulfate. F. KRAUSS AND G. JÖRNS. *Tonind.-Ztg.* **54**, 1467–8, 1483–4(1930).—The behavior of the hydrates of $CaSO_4$ depends much upon the previous history, upon the grain size and upon the exptl. conditions, so that the lack of agreement among previous investigators is plain. By starting with freshly pptd. dihydrate and heating to above 70° to start the reaction and then cooling quickly to hinder the formation of anhydrite, it is possible to get pure hemihydrate. The change takes place at 59° and at 7 mm. in the absence of air. The hemihydrate has a zeolitic character, confirming the work of Linck and Jung (*C. A.* **18**, 3566). F. O. A.

Catalytic reduction of carbon monoxide under ordinary pressure. VI. The action of an iron catalyst on carbon monoxide formation. SHINJIRŌ KODAMA. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 299–400(1930).—See *C. A.* **25**, 496. E. M. SYMMES

The lime industry in Canton. B. F. WONG. *Science J.* (China) **1**, 47–58(1929).—The old type of kiln yields an irregular product and can no longer compete with the foreign product. Methods of improving the old kiln are suggested. W. H. A.

Forgotten methods of potash manufacture and their use in the nitrogen and zinc industries. BRUNO WAESER. *Metallbörse* **20**, 2611–2(1930).—Wood ashes contained some Na_2CO_3; only tartar gave pure K_2CO_3. Vinasse was also burned to give high-grade K_2CO_3. K_2SO_4 was converted into K_2CO_3 by the Leblanc process. K_2SO_4-$MgSO_4$ mixt. was reduced with C, and $BaCO_3$ reacted with K_2SO_4. K_2SO_4 was converted to K_2SiO_3, and the latter causticized to K_2CO_3. K_2SO_4 was causticized by PbO. Thomas slag was heated with Fe ore and silicate in a blast furnace to make Fe-P-Mn alloys; the latter were then treated with K_2SO_4 to give alkali phosphate, which was causticized by $Ca(OH)_2$. Alkali chlorides were reacted with $PbCl_2$. KCl was pptd. by H_2SiF_6, and K_2SiF_6 causticized by $Ca(OH)_2$. Electrolysis was used in 1851. An important method was $2KCl + 3(MgCO_3.3H_2O) + CO_2 = 2(KHCO_3.MgCO_3.4H_2O) + MgCl_2$, $2(KHCO_3.MgCO_3.4H_2O) + Mg(OH)_2 = K_2CO_3 + 3(MgCO_3.3H_2O) + H_2O$. Another method was $8KCl + 10ZnO + 11CO_2 + 8H_2O = 4K_2O.6ZnO + 11CO_2.8H_2O + 4ZnCl_2$, the

double salt in hot water giving $4K_2CO_3 + 6ZnCO_3 + CO_2 + 8H_2O$. KCl and $NH_4CO_2NH_2$ in liquid NH_3, heated with a little H_2O, give NH_3, CO_2 and K_2CO_3. E. M. S.

Potash in 1929. A. T. COONS. Bur. Mines, *Mineral Resources of the U. S. 1929*, Pt. II, 139–45(preprint No. 12, published December 2, 1930). E. H.

Salt, bromine and calcium chloride in 1929. A. T. COONS. Bur. Mines, *Mineral Resources of the U. S. 1929*, Pt. II, 147–60(preprint No. 13, published December 8, 1930).

Elimination of silica in treatment of leucite with acid. GIAN A. BLANC. *Atti III congresso naz. chim. pura applicata* 1930, 226–30.—Repeated recirculation of the saline acid soln. through granular leucite eliminates SiO_2. E. M. SYMMES

Greensand bibliography (SHREVE) 8. Apparatus for separating solids from gases [for furnaces producing SO_2] (Fr. pat. 690,558) 1.

Die Ammoniaksynthese und das Casaleverfahren. Auf Veranlassung der Ammonia Casale s. a. veröffentlicht. Rome: L'Universale. 44 pp.

KAUSCH, O.: **Der Graphit.** Bd. 24 of "Monographs Kohle-Koks-Teer." Halle, Wilhelm Knapp. 224 pp. Unbound, M. 25; bound, M. 26.70. Reviewed in *Colliery Guardian* 141, 1140; *Ceram Abstracts* 9, 1059(1930).

Boric acid. CHEM. FAB. GRÜNAU LANDSHOFF & MEYER A.-G. Ger. 510,421, Oct. 23, 1929. Borax and H_2SO_4 are added to a satd. soln. of Na_2SO_4 at a temp. of 100°. The pptd. anhyd. Na_2SO_4 is sepd., and the soln. is cooled to 30–35°, whereupon $B(OH)_3$ free from sulfate crystallizes out and is sepd. Fresh amts. of borax and H_2SO_4 are then added to the mother liquor. The method takes advantage of the peculiar soly. properties of Na_2SO_4.

Hydrocyanic acid. I. G. FARBENIND. A.-G. (Reinhold Fick and Fritz Nicolai, inventors). Ger. 510,407, May 1, 1923. Addn. to 485,989 (*C. A.* 24, 1185). The method of 485,989 for the production of HCN by passing $HCONH_2$ and NH_3 over catalyzers at 400° is modified by using $HCOONH_4$ or a mixt. of $HCOONH_4$ and $HCONH_2$ instead of $HCONH_2$ and NH_3. HCOOH may also be added. Cf. *C. A.* 25, 562.

Phosphoric acid. I. G. FARBENIND. A.-G. Fr. 36,845, April 27, 1929. Addn. to 655,062 (*C. A.* 23, 3780). In the process of Fr. 655,062 a part of the phosphoric acid obtained in the double decompn. is each time added to the mixt. of crude phosphate and H_2SO_4 during the next operation.

Phosphoric acid. SOC. D'ÉTUDES POUR LA FABRICATION ET L'EMPLOI DES ENGRAIS CHIMIQUES (R. Flatt and E. Rist, inventors). Fr. 688,801, Jan. 24, 1930. Phosphoric acid is prepd. by heating $CaH_4(PO_4)_2$ with water preferably in an autoclave to above

100°, filtering, and concg. the filtrate by evapn. until pptn. of the non-hydrolyzed phosphate is complete.

Concentration of phosphoric acid. EMIL COLLETT. Fr. 691,296, Mar. 6, 1930. H_3PO_4, obtained from Ca phosphates and H_2SO_4, and solns. of phosphates, obtained by the action of NH_3 on this H_3PO_4, are concd. in Fe-Si vessels contg. 12–18% of Si, after reducing the content of acid F compds. in the H_3PO_4 soln. to less than 2 g. per l.

Preparing phosphoric acid and hydrogen. V. N. IPAT'EV. Russ. 44,431, April 6, 1929. P, PH_3 or lower oxidation products of P are oxidized by water under pressure and at high temp. (cf. *C. A.* **24**, 5946) in the presence of catalysts of the first and the eighth groups of elements of the periodic system. These elements are either sol. in the original products at the beginning, or they may dissolve temporarily in the first stages of the process, while during the process proper they sep. in the form of a ppt. contg. a catalytically active metal.

Nitric acid. AMMONIAQUE SYNTHÉTIQUE ET DÉRIVÉS (SOC. ANON.). Fr. 36,978, May 27, 1929. Addn. to 651,093 (*C. A.* **23**, 3312). NH_3 is oxidized at atm. pressure and, after condensation of the water vapors formed by the reaction, the nitrous oxides are compressed. Only a part of the reaction water is used for the reaction with the oxides of N, while the excess is eliminated immediately after the condensation. The dil. acid contg. the nitrous oxides is transformed to concd. acid by oxidation with compressed O at a raised temp.

Apparatus for the recovery and concentration of vapors of nitric and sulfuric acids. ARMAND G. VAUGUÉ. Fr. 36,872, May 7, 1929. Addn. to 654,055 (*C. A.* **23**, 3779). Constructional improvements are described.

Sulfuric acid. HUGO PETERSEN. Ger. 512,318, Oct 13, 1926. See Brit. 270,988 (*C. A.* **22**, 1657).

Chamber for sulfuric acid manufacture. MARIO COLOMBO. U. S. 1,788,482, Jan. 13. In the upper portion of the chamber are a plurality of sections of trapezoidal shape, these sections corresponding in width to the width of the chamber but of predetd. breadth and depth; pipes connect the portions of the chamber between the sections.

Sulfuric acid and hydrochloric acid. SOC. DES PHOSPHATES ET SUPERPHOSPHATES DE TEBBAKA and YVES LE MONIÈS DE SAGAZAN. Fr. 690,603, May 3, 1929. H_2SO_4 and HCl are made by the reaction of Cl and SO_2 in the presence of water to give a soln. of H_2SO_4 and HCl. The soln. is heated to above 100° to remove the HCl, and the rest is concd.

Ammonia. NITROGEN ENGINEERING CORP. Ger. 510,711, April 3, 1928. See Fr. 651,899 (*C. A.* **23**, 3546).

Mixing air with ammonia. H. PAULING. Brit. 334,448, Jan. 7, 1929. A mixt. of air and NH_3 under pressure is prepd. by passing a stream of compressed air countercurrent to a strong soln. of NH_3. App. and details of operation are described.

Storing alkali metals, etc., in capillary tubes. INTERNATIONAL GENERAL ELECTRIC CO. Ger 512,261, Aug. 1, 1928. See Brit. 296,347 (*C. A.* **23**, 2538–9).

Alkali metal hypochlorites. V. SZIDON. Brit. 334,364, Aug. 14, 1929. Solid or semi-solid products, suitable for bleaching purposes, are obtained by adding to aq. solns. of the hypochlorites compds. such as Na laurate or caprylate. Other materials such as Na_2CO_3 or Na silicate also may be added.

Recovering alkali metal sulfite from fusion liquors. CARL L. MASTERS (to Elko Chemical Co.). U. S. 1,788,955, Jan. 13. Na sulfite is recovered from a phenol soln., such as that resulting from alkali fusion of org. sulfonates, by distg. off the phenol with steam, cooling the residual soln. to about 0° and sepg. the Na sulfite crystals formed from the cooled soln. A diagram of app. arrangement is given.

Alkaline earth cyanamides. NIKODEM CARO and ALBERT R. FRANK (Heinrich Franck, inventor). Fr. 689,590, Feb. 7, 1930. In the manuf. of alk. earth cyanamides from alk. earth carbonates, CO and synthetic NH_3, the NH_3 is produced from H prepd. partially or wholly by means of CO. The reaction of NH_3, CO and carbonate is used for the prepn. of the H, a closed cycle being obtained. Fr. 689,591 describes the prepn. of $CaCN_2$ by calcining $(NH_4COO)_2Ca$ and fixing on the product obtained, in a second step, NH_3 and CO to transform it to $CaCN_2$ at a temp. between 600° and 800°. The $(NH_2COO)_2Ca$ is prepd. by the reaction of aq. ammoniacal solns. of NH_2COONH_4 with compds. of Ca such as $Ca(OH)_2$, and cooling to sep. $(NH_2COO)_2Ca$. Cf. *C. A.* **25**, 175.

Dehydrating crystal hydrates. G. A. YAKOVKIN. Russ 26,386, April 10, 1928. Crystals are dehydrated by passing over them vapors of solvents which are not miscible

with water and do not react chemically with the dehydrated compd. Such solvents are, for example, gasoline, kerosene or ligroin vapors.

Preparation of iodates. O. Yu. Magidson and A. G. Baichikov. Russ. 62,756, Jan. 20, 1930. Free I is oxidized by hypochlorites in H_2SO_4 medium in the presence of a chloride in the cold.

Phosphates. Jean Margoles. Fr. 689,302, Jan. 6, 1930 Natural phosphates are rendered sol. by mineral acids by introducing the phosphate and then adding the amt. of acid strictly necessary for transforming it to a sol. form. Cf. *C. A.* **24**, 4361.

Phosphates and nitrates. Francesco C. Palazzo and Fortunato Palazzo. Fr. 689,277, Nov. 16, 1928. $CaHPO_4$ and synthetic nitrates are made by using as starting materials natural phosphates, HNO_3 and an alk. base which may be NaOH, NH_4OH or KOH. Details of the process are given.

Metal carbonyls. I. G. Farbenind. A.-G. Fr. 691,100, Mar. 5, 1930. Carbonyl compds. of metals are made by submitting substances contg. the metals to a reduction with solid or liquid reducing agents rich in ashes, and then treating with CO. An example is given of the treatment of pyrites cinders contg. 55% of Fe.

Compounds of aluminum. Chemische Fabrik vorm. Sandoz. Fr. 689,587, Feb. 7, 1930. Stable compds. of Al clearly sol. in water are made by combining Al with gluconic acid in the manner used for making salts, *e. g.*, by double decompn. of Al salts with alk. earth gluconates.

Aluminum compounds; phosphoric acid. I. G. Farbenind. A.-G. (Otto Balz, Adolf Leber and Rudolf Schulze, inventors). Ger. 512,130, May 5, 1929. Materials contg. Al and H_3PO_4 are dissolved in HCl, and the soln. is treated with HCl gas to ppt. $AlCl_3$, which can then be worked up to Al_2O_3, etc. H_3PO_4 is recovered from the residual soln.

Purification of bismuth salts. Friedrich Spira. Ger. 510,140, June 16, 1929. Bi salt soln. obtained by extg. Bi ores, etc., with a feebly acid, concd. soln. of an alkali or alk. earth chloride is treated with an oxidizing agent, *e. g.*, $KClO_3$, in such an amt. that the base-metal impurities, *e. g*, As, Sb, Sn, Mo, Fe and Mn, are present in their highest stage of oxidation. The soln. is then neutralized, whereby the impurities are pptd. Examples are given.

Potassium salts. Chemieverfahren-Ges. m. b. H. Fr. 36,992, May 31, 1929. Addn. to 673,851 (*C. A.* **24**, 2553). See Brit. 316,548 (*C. A.* **24**, 1943).

Zinc salt solutions. Metallges. A.-G. Brit. 334,458, Dec. 7, 1928. Raw materials contg. ZnO are first leached with acid as described in Brit. 302,924 (*C. A.* **23**, 4305) to ext. most of the Zn without extg. other metals present; the residue is then leached with considerable excess of acid, and the acid liquor thus obtained is treated with H_2S or a sulfide such as that of Fe or Zn to free it from metals such as Cu, Cd, As and Sb. Details for further purification of the soln. to remove residual Fe, Ni, Co, Pb, etc., also are given. Pb may be recovered as sulfate. Cf. *C. A.* **24**, 1473.

Alumina. Jean C. Séailles. Fr. 36,971, Mar. 13, 1929. Addn. to 634,430 (*C. A.* **22**, 3745). In the process of Fr. 634,430 for the extn. of Al_2O_3 from non-halogenated ores, NaCl or $CaCl_2$ is added to the water used, whereby the reaction takes place with 3 mols. of CaO instead of 4 for each mol. of Al_2O_3. Cf. *C. A.* **25**, 780.

Aluminum formate solution. Zschimmer & Schwarz Chemische Fabrik Dölau (Oskar Jochem, inventor). Ger. 510,575, Mar. 15, 1929. $(HCOO)_3Al$ soln. of over 25% strength is prepd. by treating solid $(HCOO)_2Ca$ with concd. $Al_2(SO_4)_3$ soln. at temps. ranging from room temp. to 70°. Examples are given.

Crystals of ammonium chloride. Imperial Chemical Industries, Ltd. Fr 689,040, Jan. 28, 1930. Crystals of NH_4Cl are obtained by constantly stirring an aq. soln. of NH_4Cl contg. a small quantity (*e. g.*, 0.1%) of a chloride forming mixed crystals with NH_4Cl, such as a chloride of Mn, Fe, Co, Ni or Cu.

Ammonium phosphate. Soc. d'études pour la fabrication et l'emploi des engrais chim. (Pierre Jolibois, inventor). Fr. 691,332, May 21, 1929. $NH_4H_2PO_4$ is made by pulverizing the natural phosphate and then submitting it to a treatment with HCl followed by a calcination. The residue is afterward treated with $(NH_4)_2CO_3$ (or a mixt. of CO_2 and NH_3) in excess under high pressure.

Diammonium phosphate. Édouard Urbain. Fr. 691,132, May 10, 1929. $(NH_4)_2HPO_4$ is made by first pptg. $(NH_4)_3PO_4$ and then transforming the latter by heat under pressure into $(NH_4)_2HPO_4$.

Ammonium sulfate. N. V. De Bataafsche Petroleum Maatschappij. Ger. 510,331, Feb. 17, 1929. $(NH_4)_2SO_4$ practically free from sulfite is prepd. by reacting NH_3 and SO_2 in the absence of water, and then treating the product, preferably immediately after its formation, with water (or steam) and O (or air). Somewhat less

water than is theoretically necessary may be used. The process may be effected at 100–120°. App. is shown.

Ammonium sulfate and sulfur. HEINRICH KOPPERS A.-G. Fr. 689,983, Feb. 14, 1930. For the production of $(NH_4)_2SO_4$ and S from mixts. of bisulfite with sulfite or thiosulfate, polythionates with sulfite or thiosulfate, thiosulfite with SO_2 or H_2SO_4, in the presence or absence of NH_4CNS, the app. used is made of alloys of the Cr-Ni or the Cr-Ni-Fe group with or without Cu or Mo, or is covered with such alloys. If an excess of SO_2, H_2SO_4, bisulfite or polythionates is present, the conversion is not pushed to completion; this avoids attack of the metallic parts of the app. by H_2SO_4 in the converted solns.

Barium carbonate. B. LAPORTE, LTD., I. E. WEBER and V. W. SLATER. Brit. 334,709, Sept. 5, 1929. $BaCO_3$ substantially free from S compds. is prepd. by addn. of BaS, Ba hydrosulfide or other Ba-sulfur compd. to a soln. of CO_2 or $Ba(HCO_3)_2$ in such proportion that there is always CO_2 or $Ba(HCO_3)_2$ present. Details of both a continuous and a discontinuous procedure are described. Flue gas may be used and a p_H below 7 is suitable. The H_2S evolved may be used for producing S or SO_2.

Calcium cyanamide. I. G. FARBENIND. A.-G. Fr. 689,823, Feb. 13, 1930. See Brit. 333,353 (*C. A.* **25**, 564).

Calcium nitrate. APPAREILS ET ÉVAPORATEURS KESTNER. Fr. 36,618, April 3, 1929 See Brit. 329,145 (*C. A.* **24**, 5442).

Calcium nitrate and ammonium nitrate. KUNSTDÜNGER-PATENT-VERWERTUNGS-A.-G. (Frans Georg Liljenroth, applicant in Switzerland). Fr. 36,674, Apr. 10, 1929. Addn. to 663,066 (*C. A.* **24**, 472). In the process of the prior case the $CaSO_4$ is first produced in the state of a semi-hydrate by the use of a high temp. and high concn. of the reacting soln. The semi-hydrate is afterward recrystd. to $CaSO_4$.

Dicalcium phosphate. AUGUST HOLZ (to Theodore V. D. Berdell). U. S. 1,788,952, Jan. 13. In a process for the continuous com. production of di-Ca phosphate, a soln. of an alkali metal chloride such as NaCl is electrolytically decompd. to produce H, Cl and a soln. of the alkali metal hydroxide; the Cl and an equiv. quantity of SO_2 are simultaneously passed into water to produce a mixt. of HCl and H_2SO_4. Tri-Ca phosphate is treated with this acid mixt., $CaSO_4$ is sepd. from the resulting reaction products by filtration, and the filtrate is treated with alkali metal hydroxide, thus producing di-Ca phosphate and regenerating the alkali metal chloride.

Dry carbon dioxide. DRYICE EQUIPMENT CORP. Fr. 690,394, Feb. 21, 1930. Water and other liquid impurities are sepd. from liquid CO_2 by evapg. part of the CO_2 to freeze out the water, etc.

Forming and compacting solid carbon dioxide. MASCHINENFABRIK ESSLINGEN and J. STOFFELS. Brit. 334,682, Aug. 7, 1929. App. and various details of operation are described.

Freeing hydrogen of phosphine. NAUCHNUI INSTITUT PO UDOBRENIYAM IMENI YA. V. SAMOILOVA V. S. N. KH. SSSR. and I. A. MIRKIN. Russ. 69,446, May 3, 1930. HCl is added to the H, and the whole is compressed up to 100 atms. at a temp. of 30–40°.

Hydrogen peroxide. J. D RIEDEL-E. DE HAËN A.-G. (Leo Löwenstein, inventor). Ger. 510,064, July 22, 1924. The distn. of H_2O_2 from solns. of $H_2S_2O_8$ or persulfates, etc., is effected by drawing the soln. upwardly through narrow, externally heated tubes.

Oxidizing hydrogen sulfide. I. G. FARBENIND. A.-G. Ger. 510,488, June 4, 1925. H_2S is oxidized, and the oxidation products are obtained as NH_4 salts, by passing a gas contg. H_2S and NH_3, *e. g.*, coke-over gases, with an addn. of O if necessary, at a raised temp. over a catalyst comprising 2 metals, one of which is capable of binding S, *e. g.*, Fe, Ni or Cu, while the other acts as an oxygen-carrier, *e. g.*, W, V or Cr. Oxides or oxygenated salts of the metals may also be used. Addnl. details and an example are given.

Oxidizing hydrogen sulfide to anhydrous sulfuric acid. AKZIONERN. O-VO KOKSOBENZOLNOI PROMUISHLENNOSTI "KOKSOBENZOL." Russ. 21,188, Nov. 25, 1927. H_2S is oxidized to SO_3 by iron oxides and Mn catalysts. These catalysts are pptd. in a fine layer on silicic acid, which is first mixed with a soln. of the above metal salts and then dried in a stream of air or oxygen. A. A. BOEHTLINGK

Phosphorus oxychloride and thionyl chloride. JOHN G. SCHUDEL (to Elko Chemical Co.). U. S. 1,788,959, Jan. 13. Reaction is effected between a mixt. of SO_2, Cl and PCl_3. An arrangement of app. is described. Cf. *C. A.* 24, 2556.

Regenerating potassium ferricyanide. RICHARD BRANDT. Ger. 511,898, July 4, 1928. Addn. to 503,118. App. for the method of Ger. 503,118 (*C. A.* 24, 4994) is described.

Preparing potassium and sodium permanganates. M. I. BELOTZERKOVSKII. Russ.

70,674, May 24, 1930. Mn oxides which were preliminarily hydrated are evapd. to dryness together with the alkali and are then oxidized with air or with O in the presence of CaO, which combines with the water and makes the mass fluffy.

Sodium carbonate. HERMAN B. KIPPER. U. S. 1,789,235, Jan. 13. A mixt. of NaCl brine, NH_3, H and CO_2 is rapidly stirred and simultaneously cooled, externally and internally, in a stationary vessel to ppt. $NaHCO_3$ and produce an NH_4Cl soln. The inner surface of the vessel is subjected to scraping at a rate slower than the stirring, and the ppt. and NH_4Cl are expelled from the vessel and sepd by filtration. The $NaHCO_3$ is heated by hot waste gases from a lime kiln to decompose it into Na_2CO_3, CO_2 and steam. App. is described.

Sodium silicate. EDWARD A. TAYLOR and WORTHINGTON T. GRACE (to Canadian Industries, Ltd.). Can. 307,399, Jan. 6, 1931. A purified soln. of Na silicate is produced by dissolving water glass by the action of water and steam, adding less than 1% of $Ca(OH)_2$ and Na_2CO_3 (on the wt. of the silicate) and removing the ppt. formed.

Sodium sulfide and other substances. KALI-CHEMIE A.-G. Fr. 36,788, Jan. 30, 1929. Addn. to 595,282. Na_2S and other substances are obtained in granular form or small pieces by dropping them in a molten state on to a surface previously treated with very viscous oils or fats having a repellent action on water.

Zinc oxide. JOSEPH M. H. CORNILLAT. Ger. 499,536, Aug. 4, 1926. ZnO is obtained by melting down metallic Zn by burning mazout in a furnace, and keeping the molten mass in const. motion. The furnace is connected with condensers, so that the vapor formed is oxidized and condensed. The app. is described.

Zirconium oxychloride. KALI-CHEMIE A.-G. (Friedrich Rüsberg and Paul Schmid, inventors). Ger. 510,574, Oct. 28, 1926. A fused Zr-CaO mixt. is treated with HCl and $CaCl_2$ in such proportions that a neutral soln. is produced which during crystn. out of the oxychloride, is satd. with $CaCl_2$ and supersatd with the oxychloride. Thus, a fused mass contg. 48% CaO, 31% ZrO_2, 14% SiO_2 and 7% Fe + Al_2O_3, is powd. and treated with $CaCl_2$ lye. $ZrOCl_2$ crystallizes out on cooling.

Arsenic. OTAVI MINEN- UND EISENBAHNGESELLSCHAFT (Karl Kubel, inventor) Ger. 510,750, July 11, 1928. Materials contg. As, especially those contg As and Cd, are worked up by heating with alkali lye to about 200° under suitable pressure. The As is then leached out. Oxides of As contg. Pb and Cd are treated in the same way to separate the As and Pb from the Cd. The Pb is then pptd. from the As-Pb soln by leading in CO_2. The As which crystallizes out from the alkali lye contains alkali hydroxide and is sepd. therefrom by hydrolysis. Several examples are given.

Iodine. OLINTO D. LUCIA. Fr. 688,854, Jan. 25, 1930. I is extd. from solns of salts of I by treating the solns. after filtration in an emulsifier with reagents capable of liberating the I and a solvent capable of dissolving it.

Extracting iodine from dilute solutions. P. I. KAMINSKII. Russ. 68,574, April 18, 1930. Straw, sawdust, etc., are used to absorb I compds from dil. soln. The absorbents are then treated with Na_2CO_3 and burned, and the I is extd. from the ashes by one of the known methods.

Purification of oxygen or hydrogen. ARMAND MAUSELIN. Fr. 691,315, May 16, 1929. H or O in mixts. contg. one of these in predominance is purified by feeding an explosion motor with the mixt. contg. them. The resultant product contains steam and the gas which was predominant. The process may be applied in the manuf. of chlorates by electrolysis, by collecting the H, O and Cl, sepg. the Cl and then treating the mixt. of H and O as above.

Condensing phosphorus from gases and vapors. HERMANN LANG (to I. G. Farbenind. A.-G.). U. S. 1,788,838, Jan. 13. The gases or vapors, at a temp. below the dew point of P, are subjected to the action of rapidly moving, finely divided drops of liquid such as water, acid solns., etc., under such conditions of subdivision and velocity as to form an emulsion of the P with the liquid.

Graphite purification. EUGÈNE RABETRANO. Fr. 691,128, May 10, 1929. See Brit. 328,697 (*C. A.* 24, 5445).

Treating phosphatic rocks. KUNSTDUNGER-PATENT-VERWERTUNGS-A.-G. Fr. 690,013, Feb. 14, 1930. In the treatment of phosphatic rocks with HNO_3 and K_2SO_4, a part of the soln. obtained in the extn. process is sepd. from the pptd. $CaSO_4$ and freed from part of its content of KNO_3 by cooling and crystn. and is then employed as a dilg. agent in the continuation of the extn. treatment. During the greater part of the reaction the amt. of K_2SO_4 is deficient, the amt. necessary to ppt. the lime remaining in soln. being added toward the end of the reaction. The $CaSO_4$ is pptd. as its dihydrate in the presence of an NH_4 salt.

Purifying carbon. I. G. FARBENIND. A.-G. Brit. 334,190, May 27, 1929. Carbon

obtained by splitting CO by use of metals of the eighth group of the periodic system is freed from carbonyl-forming metals or their carbides by treating the C at a temp. of 50–210° with CO (which may be under pressure) after a preliminary treatment with H or inert gas at 400–500° or with a weakly oxidizing gas at 200–400°. A small quantity of S may be added to serve as a catalyst for the formation of carbonyl.

Active carbon. I. G. FARBENIND. A.-G. (Ludwig Klebert, inventor). Ger. 510,090, Dec. 14, 1928. See Fr. 686,322, (*C. A* 25, 565).

Improving active carbons. CORNELIS LOURENS (to General Norit Co., Ltd.). U. S. 1,788,466, Jan. 13. For improving its adsorption efficiency, an active C is prepd. contg. from 0.3 to 5.0% of HCl or other acid.

Adsorbing and filtering materials containing active carbon. MAX HAMBURG and EDUARD JALOWETZ. Ger. 512,018, Jan. 7, 1928. See Austrian 116,236 (*C. A.* 24, 2560).

Regenerating absorbent charcoal. COMPAGNIE FRANÇAISE DE PRODUITS ORGANO-CHIMIQUES (Anciennement soc. anon. des Engrais et Noir animal). Fr. 36,985, May 29, 1929. Addn. to 636,165 (*C. A.* 23, 246). The admission of steam into the absorber is greatly reduced, the steam being used only for driving out the air or gases therein.

Bone black. BAUGH & SONS Co. Ger. 512,484, April 4, 1930. Bone black is prepd. by a continuous process in which the bones are first dry-distd. at a relatively low temp., *e. g.*, 500–700°, for a relatively long time, *e. g.*, 1–2 hrs.; the charred bones are then heated at a higher temp., *e. g.*, 800–1100°, for a short time, *e. g.*, 5–15 mins. App. comprising two externally heated rotary retorts is described.

Apparatus for making lampblack from petroleum hydrocarbons. I. I. BEGROV. Russ. 14,204, Feb. 18, 1927. A coil consisting of a number of banks is placed in a furnace. Light petroleum fractions are admitted into the upper end of the coil after passing a hydraulic seal. The oil, being gradually heated during its downward movement, is partially converted into vapor, which is discharged through perforations provided in the lowest pipe. A liquid seal outside of the furnace connected to one of the pipe banks in the furnace serves to discharge the excess of oil which was not evapd. The oil pressure is regulated by a valve attached to a manifold connected in front of the liquid seal for hot oil. The vapors are burned to produce lampblack.

Catalyst suitable for ammonia oxidation. BAMAG-MEGUIN A.-G. Brit. 334,466, Feb. 8, 1929. A wire netting is used composed of a metal such as Rh or an alloy of Rh and Pt together with some wires of pure Pt

Catalysts suitable for oxidizing sulfur dioxide to trioxide. IMPERIAL CHEMICAL INDUSTRIES, LTD., and J. A. WEIL. Brit. 334,268, June 1, 1929. Catalysts are prepd. by admixt. of a V compd (such as an alkali metal vanadate or vanadite, vanadyl salts or double salts such as vanadyl sulfate or NH_4 vanadyl oxalate) with a siliceous diluent such as ground silica, siliceous brick, sand or kieselguhr and siliceous material in the form of a wet hydrogel such as wet silica gel. The mixt. may be formed into pellets or other masses and treated with burner gas at 450–500°.

Catalytic materials. HENRY DREYFUS. Fr. 691,210, Mar. 5, 1930. Catalytic materials, which are exhausted or poisoned in gas reactions such as the synthesis of MeOH, are reactivated or regenerated by submitting them to the action of gases rich in H at temps. not appreciably above those used in the catalytic operation.

Catalyst supports. MONSANTO CHEMICAL WORKS. Fr. 691,356, Nov. 21, 1929. A support for catalysts consists of a porous mineral substance such as kieselguhr, covered with a layer of SiO_2 and preferably having the form of uniform pellets. The support may be used for compds. of V or Pt in the manuf. of SO_3 from SO_2 and O.

Condensation products. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 140,428, June 15, 1928. The condensation product from 1 mol. urea and at least 2 mol. CH_2O is treated with thiourea in such quantity that there is at least 2 mol. CH_2O to each mol. of the urea-thiourea mixt. The end product is worked up in such a way that most of the free CH_2O is taken up. Thus, 120 parts urea is dissolved in 334 parts CH_2O (36%) and mixed with blood charcoal and filtered. The soln. is neutralized with KOH and 45 parts thiourea are added. On leaving for 2 days the free CH_2O decreases from 6 to 0.5 vol. %. Other examples are given.

Hardening formaldehyde-urea condensation products. I. G. FARBENIND. A.-G. (Robert Griessbach and Müller von Blumencron, inventors). Ger. 510,513, Oct. 17, 1925. CH_2O and urea condensation products and derivs. are hardened by subjecting the surface to the action of gaseous or dissolved SO_2. The reaction may be carried out either cold or warm. Examples are given.

Impregnating fibrous materials with phenolic condensation products, etc. I. J. NOVAK. Brit. 334,232, May 27, 1929. An impregnating material is prepd. by con-

densing cresylic acid with formaldehyde in the presence of at least 1 mol. proportion of NH_3 for every 4 mol. proportions of cresylic acid, mixing this condensation product with china wood oil, and heating the mixt. until it is sufficiently clarified to remain limpid when cool. Any excess of cresylic acid may be removed by adding $(CH_2)_6N_4$ or polymerized formaldehyde.

Compositions resistant to the electric arc. BAKELITE CORP. Fr. 689,126, Jan. 30, 1930. Compns which are resistant to the elec. arc are prepd. by condensing together by heat a fatty oil such as tung oil and a phenol in the presence of a promoter (such as phosphoric acid), the phenol being in excess with respect to the amt. necessary to produce a resinoid with the fatty oil, then eliminating the free phenol or combining it with a hardening agent such as hexamethylenetetramine. A cellulosic material may be added as a filler.

Plastic compositions. I. G. FARBENIND. A.-G. (Karl Daimler, Kurt Sponsel and Gerhard Balle, inventors). Ger. 508,930, Feb. 14, 1925. Films, folios, coatings, etc., insol. in water and difficult to swell, are prepd. from cellulose ethers and albuminous material in the presence of NH_3 or its volatile derivs. Thus, a mixt. of Me cellulose soln., tannin, NH_3 and water are poured on a glass plate to form a film. Other examples are given.

Plastic materials. DEUTSCHE GASGLÜHLICHT-AUER-GES. M. B. H. Fr. 688,962, Jan. 27, 1930. Azelaic acid is esterified with glycerol, with or without the addn. of condensation agents Part of the glycerol may be replaced by other mono- or polyhydric alcs., and part of the azelaic acid may be replaced by other uni- or multi-valent acids.

Plastic materials from carbohydrates and alkylene oxides. I. G. FARBENIND. A.-G. Brit. 334,282, June 4, 1929. Materials such as potato meal, dextrin or cotton are treated with ethylene oxide or propylene oxide and alkali soln. such as NaOH of 20% strength or less, at ordinary temp. and without application of pressure, to form water-sol. products of varying soly. in org solvents.

Thermoplastic material. SIMMONS CO. Fr. 691,094, Mar. 5, 1930. A material of cellular structure which sets on heating is made by mixing a substance which sets on heating, such as a synthetic resin, with a substance which liberates gas under the action of heat, such as hexamethylenetetramine, and heating the mixt. in a hermetically sealed mold.

Artificial masses. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 141,223, Oct 23, 1928, and 141,224, Nov. 6, 1928. One mol. of an aromatic amine is condensed with not more than 1 mol. of an aldehyde in the presence of an acid, and the resinous product is pressed with a further amt. of aldehyde after removal of the acid. Thus, 1 mol. $PhNH_2$ is condensed with 1 mol. 40% CH_2O in HCl. The acid is removed and the resin (m. 180–200°) hardened by further CH_2O. Other examples are given The CH_2O hardening agent may be replaced by alc., acetone, C_6H_6, etc., and the whole pressed.

Porous masses. A. A. BRYUSHKOV, P. I. YUDINSON and P. N. SHABLUIKIN. Russ. 66,013, Mar. 9, 1930. Porous masses prepd. with saponin alginate froth are characterized by the addn. of tripoli contg. a natural admixt. of lime and preliminarily burned at a temp. not exceeding 1000°. This mixt. is given the required shape, and it is then steam-treated in boilers.

Adhesive compositions. BAKELITE CORP. Fr. 691,293, Mar. 6, 1930. An adhesive is composed of a wax-like chlorinated $C_{10}H_8$ and a natural resin or deriv of a natural resin, such as colophony, copal, latex, rubber or esters of resins.

Colloidal solutions or pastes. I. G. FARBENIND. A.-G. Fr. 689,711, Feb. 11, 1930. Colloidal solns. or pastes of insol. substances, such as inorg. salts or oxides or org. dyes, are obtained by means of polymerization or transformation products of butadiene or its homologs substituted in the 1 position or 1 and 4 positions, which do not distil without decompn., or their derivs., alone or with other substances. Cf. *C. A.* 25, 420.

Gluing wood with starchy materials. EUGEN ABRAMOWITSCH. U. S. 1,788,608, Jan. 13. Starch-contg. substances such as corn, potato or rice flours in unconverted state are applied to wood surfaces to be glued, and the substances are then converted into strong adhesives by heating under pressure to about 90°. Polymerized formaldehyde or $MgCl_2$ may be added.

Separating soluble substances after crystallization together. IMPERIAL CHEMICAL INDUSTRIES, LTD., and H. E. COCKSEDGE. Brit. 334,169, March 14, 1929. The sepn. may be effected by sieving followed by elutriation in an inert liquid, and the size of the particles may be controlled, during crystn., by seeding, addn. of supersatd. solns. or

addn. of colloids such as gelatin. Examples are given of the sepn. of $NaNO_3$ and KNO_3 by sieving followed by elutriation in a soln. satd. with both salts, and of the sepn. of Na_2CO_3 and NaCl by control of particle size during crystn. followed by sieving or elutriation or both.

Furnace for powdered materials such as limestone rocks or cement. JULIEN BELLAY. Fr. 36,855, May 1, 1929. Addn. to 663,106 (*C. A.* **24**, 699).

Superposed-hearth rabble furnace suitable for roasting sulfide ores. HANS KLENCKE. U. S. 1,788,767, Jan. 13.

Derivatives of iron carbonyl. I. G. FARBENIND. A.-G. (Robert Zell, inventor). Ger. 512,223, Apr. 8, 1928. Compds. such as $Fe(CO)_4Br_2$ and $Fe(CO)_4(CNS)_2$ are prepd. by reacting an iron carbonyl with a halogen, CN or CNS in the absence of water. The products are more stable to heat than $Fe(CO)_4$ and yield pure CO when treated with water. They may be used for *destroying vermin.*

Synthetic stones. I. G. FARBENIND. A.-G. Fr. 689,679, Feb. 10, 1930. The surface of synthetic stones such as corundum or rubies is made smooth by a short treatment with fused borax.

Condensation products. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 37,012, June 6, 1929. Addn. to 638,082 (*C. A.* **23**, 248). The final treatment of concn., in the presence of a catalyst, of the soln. obtained after the addn. of thiourea or a mixt. of thiourea and urea to the primary condensation soln. is carried out only after the greater part of the free CH_2O has been fixed and this in a neutral medium at ordinary or slightly raised temp.

Halogenated albumin from blood serum. AKT.-GES. FÜR MEDIZINISCHE PRODUKTE. (Ernst Flater, inventor). Ger. 510,305, Mar. 13, 1926. Crude blood serum is treated with an alc. soln. of a halogen. Examples are given.

Steeping dried casein. FRITZ SCHMIDT. Ger. 510,693, Sept. 20, 1924. Dried casein is steeped in a mixt. of water and water-sol., neutral, readily volatile org. substances such as alc., acetone, ethyl lactate, etc., and warmed to a temp. well below 100°. The process is suitable for the manuf. of *artificial horn, etc., from casein.*

Agglomerates. COMPAGNIE FRANÇAISE D'EXPLOITATION DES PROCÉDÉS PLINATUS. Fr. 36,636, Jan. 3, 1929 Addn. to 665,430 (*C. A.* **24**, 933). Fillers such as sawdust are added to the agglomerates of the prior case.

Filling compositions. BAKELITE CORP. Fr. 691,294, Mar. 6, 1930 A filling or coating compn. contains chlorinated $C_{10}H_8$ (corresponding with $C_{10}H_4Cl_4$) 39, gilsonite 27 and fossil wax 34%. Bitumen may be added to the compn.

Material for gaskets or sheet packing. MERRITT T. RHODES. U. S. 1,789,114, Jan. 13. Asbestos paper free from inorg. filler is treated with an admixt. of glue, glycerol and formaldehyde and cured by heat (the asbestos fiber remaining in the product substantially the same as in the asbestos paper), and the material is provided with a flame-proof coating formed of casein, formaldehyde and phenol. An acid- and moisture-proof, heat-resisting material is thus obtained.

Etched printing plates. A. AXTHELM. Brit. 334,629, June 13, 1929. The design on the plate is coated with resin or other suitable resist powder, and the plate is then exposed to the action of a vapor from which liquid is pptd. to convert the powder into a smooth layer. App. is described.

Lithographic printing plates. RUDOLPH A. GLASER (to Gardner Abbott, as trustee). U. S. 1,789,138, Jan. 13. An image is projected directly onto the plate by the action of high-intensity actinic light rays upon a lithographic coated printing surface permeable to such a light, the light-struck portions of the plate are impregnated with an asphaltum ink soln. to form an ink-receiving image, the light-struck portions of the coating are washed away, and the bare surface of the plate is cleaned to form a surface capable of taking moisture and resisting ink.

Composition for making and treating rollers of printing apparatus. S. BEAUNE. Brit. 334,183, May 22, 1929. Inking rollers are provided with an elastic and easily cut coating, such as may be formed of wax, whitening, gelatin and glycerol; wiping rollers have a coating of similar compn. which are rinsed with alc. and then treated in a satd. alum soln., kept at about 3° for at least 24 hrs and rubbed with chamois leather to prepare the rollers for use. A solvent such as CCl_4 may be used for cleaning. Various structural details are also described

Wetting agents. I. G. FARBENIND. A.-G. Fr. 689,357, Feb. 3, 1930. Derivs. of sulfuric esters of higher fatty acids or hydroxy fatty acids are prepd. by treating sulfuric esters of higher fatty acids or hydroxy fatty acids with alkylating agents or treating the alkali salts with univalent lower alcs., preferably with the addn. of an acid agent acting as a catalyst. Examples are given. The products have high wetting powers.

Wetting, etc., agents. DEUTSCHE HYDRIERWERKE A.-G. Fr. 690,352, Feb. 21, 1930. A product which may be used as a wetting, cleaning, washing or emulsifying agent is composed of alkali salts of phosphoric and boric acids with sulfonates of org. materials and with or without alcs. of high mol. wt. Thus, a mixt. of Adrinople red oil, borax and terpineol may be used.

Wetting and emulsifying agents. BRITISH DYESTUFFS CORP., LTD. Fr. 36,744, Mar. 19, 1929. Addn. to 635,264. The sulfonation of the prior case is carried out at a temp. of or below 65°.

Artificial sponge. I. G. FARBENIND. A.-G. Fr. 36,662, Mar. 28, 1929. Addn. to 672,136 (*C. A.* 24, 2257). In the manuf. of artificial sponge from viscose and a filling material, mixts. of neutral salts free from water of crystn. and neutral salts contg. water of crystn. are used as filling material. An example is given in which a soln. of viscose is mixed with fibrous material, crystd. Na_2SO_4 and calcined Na_2SO_4. Cf. *C. A.* 24, 500.

Artificial sponges. I. G. FARBENIND. A.-G. Fr. 37,092, Mar. 29, 1929. Addn. to 672,136 (*C. A.* 24, 2257). Artificial sponges are made from viscose and a filling substance, the elimination of which gives the desired porous structure, fibrous materials being used if necessary. The mixt., after molding, preferably with heat, is submitted to a complementary treatment in an atm. of air, gases or vapors kept under pressure and satd. with steam, and to which a gas combining with bases, such as CO_2, may be added. Cf. *C. A.* 24, 500.

Compositions resistant to liquids. BAKELITE CORP. Fr. 691,295, Mar. 6, 1930. An artificial moldable compn. contains a phenolic resin and a substance which prevents deformation, occasioned by absorption, of objects made from the compn., *e. g.*, 3–5% of water.

Bleaching compositions. PILOT LABORATORY, INC. Brit. 334,531, May 27, 1929. Higher fatty acid peroxides and peroxy compds such as valeryl, caproyl, capryl, lauryl, palmityl, oleyl, stearyl and ricinolyl peroxides and peracids, suitable for *bleaching*, for use in *pharmaceutical prepns.*, for synthesis, as *bactericides*, as *internal antiseptics*, for use in *skin-bleaching creams* and in *dentrifices*, are prepd. by treating higher fatty acid chlorides with a soln. of an alkali metal peroxide preferably of a concn. not over 10%. Various details and examples are given Cf. *C. A.* 24, 4364.

Polishes. GASTON ROELANDTS. Fr. 37,088, Mar. 9, 1929. Addn. to 652,410 (*C. A.* 23, 3588). A polish for a nitrocellulose or cellulose ester varnish contains an agent which will soften without dissolving the surface. An example given contains nitrocellulose 30, AcOBu 45, toluene 18, EtOH 7 and tricresyl phosphate or butyl phthalate 20 parts.

Metal-cleaning compounds. GRINNELL JONES. Can. 307,581, Jan. 13, 1931. A metal polish comprises an intimate mixt. of Mg, Na acid tartrate and Cu oxide. An abrasive such as infusorial earth may be added.

Metal-cleaning compound. GRINNELL JONES. Can. 307,582, Jan. 13, 1931. A compn. for cleaning tarnishable metals comprises an intimate mixt. of finely divided Zn 33.3 g., Na acid tartrate 100.0 g. and Cu oxide 10 g., the mixt. being dispersed in a non-aq. medium.

Heat-producing composition. WILMER C. GANGLOFF (to The Dracket Chemical Co.). Can. 307,690, Jan 13, 1931. A heat-producing compn. comprises 19 oz. NaOH and 1 oz. Al plus a metal that does not ordinarily undergo an exothermic reaction with NaOH alone. The compn. is used for cleaning sink drain pipes, sewer pipes, sewage-disposal lines, etc.

Coating composition. RAY P. DINSMORE (to The Goodyear Tire and Rubber Co.). Can. 307,702, Jan. 13, 1931. Metallic bodies are coated with several thin films of a material comprising gelatin and polyglycerol, each film being subjected to the action of alum, formaldehyde or other tanning agent. This compn. is used for the joints of sectional bodies

Iodide paper. VIKTOR BAUSCH. JR. Ger. 512,381, Sept. 1, 1929. Iodide paper for telegraphy, particularly for transmitting pictures, contains a no. of different metal iodides, *e. g.*, KI and CdI_2, with or without ZnI_2.

Cardboard from mineral constituents. GOSUDARSTVENNOYE VSESOYUZNOYE OB'EDINENIE BUMAZHNOI PROMUISHLENNOSTI. Russ. 8630, May 10, 1926. Mined asbestos, slate and similar material are broken up into pieces, and dried to a 7–12% water content, depending on the amount of fibrous material to be later incorporated. The mixt. is disintegrated by the usual methods and sifted to sep. the mineral dust of varying grain size. The mineral fiber is then mixed with this dust in different proportions and worked up into board by the usual methods.

Inert atmospheres. WESTINGHOUSE ELECTRIC & MANUFACTURING CO. Fr.

37,091, Mar. 28, 1929. Addn. to 590,307. A deoxidizing material to establish an inert atm. over oils used for elec. app., particularly transformers, is composed of a mixt. of charcoal treated to remove constituents forming ash and H, with a substance facilitating oxidation of the charcoal at a moderate temp., such as a chloride of Co, Mn, Ni or Na, Na_2SO_4, KI or NaOH, and a binding agent. The whole is formed into a block. Constituents forming ash and H may be removed by a treatment with Cl at about 600°.

Magnetic materials. LE MATÉRIEL TÉLÉPHONIQUE (SOC. ANON.). Fr. 689,570, Feb. 7, 1930. The characteristics of magnetic materials are improved by a gaseous or solid cementation.

Magnetic cores. INTERNATIONAL STANDARD ELECTRIC CORP. Ger. 510,231, Dec. 8, 1927. In the manuf. of cores from superficially oxidized particles of a magnetizable metal, the oxide layer is produced by warming the powd. metal in an atm. richer in O than air. The metal powders may be mixed with a compd. evolving O, *e. g.*, Sb_2O_5 or PbO_2.

Diaphragms for loud-speakers, telephones, microphones, etc. H. VOGT. Brit. 334,605, June 8, 1929. Diaphragms are made from foil of an alloy formed mainly of Al (suitably 94%) together with Cu (suitably 4%) and Si (suitably 2%). Details of tempering, etc., are described.

Dental floss. CARL PFANSTIEHL. U. S. 1,789,052, Jan. 13. The floss is passed through a heated liquid bath contg. galactonic lactone and withdrawn through a superposed layer of melted waxy material such as beeswax, paraffin or ceresin. App. is described.

Fireproofing wood, textile fabrics, etc. I. G. FARBENIND. A.-G. Brit. 334,408, Sept. 28, 1929. The material is impregnated or coated with solns. or suspensions of combustion-retarding substances such as NH_4 phosphate or sulfate, silicates, or Zn salts and urea-formaldehyde condensation products (which adhere to the material and prevent crystn.). Glue, starch, etc., also may be added. Several examples with details of treatment are given. Cf. *C. A.* 24, 4364.

Foam for fire extinguishers. EXCELSIOR FEUERLÖSCHGERÄTE A.-G. Ger. 510,533, Sept 2, 1926. A device for producing foam by directing water under pressure on to powd. chemicals such as a mixt. of $NaHCO_3$, $Al_2(SO_4)_3$ and saponin is described. Cf. *C. A.* 24, 4907.

Use of methyl bromide, pentachlorothane, carbon dioxide, etc., in fire extinguishers. PYRENE CO., LTD., and J. N. HUNTER. Brit. 334,552, June 5, 1929. Various details of fire-extinguisher construction and operation are described.

Device for quenching fires in containers for inflammable liquids with carbon dioxide, etc. ERICH GRÄBER. Ger. 510,698, Dec. 6, 1924.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Antique artistic glass. E. BERL. *Chem.-Ztg.* 54, 913–4(1930).—The compn. of an ancient glass cup is 72.8% SiO_2, 19.3% K_2O + Na_2O, 5% CaO, *i. e.*, approx. that of lab. soft glass. A fragment heated in steam for 6 hrs. at 200° is strongly attacked. Restoration involves careful annealing partially to remove the network of fine cracks covering the surface. As a protective coating, cellulose ester lacquer is suggested.
B. A. SOULE

Note on the influence of various radiations on the coloration of glass. A. LECRENIER AND P. GILARD. *Rev. belge ind. verrieres* 1, 214–5(1930).—Ultra-violet radiation modifies the internal compn. of glass by producing different states of oxidation. The modifications disappear at the softening temp. The action of radioactivity may be purely phys. Some glasses are rendered radioactive and luminescent. Investigations were made on glasses of various compns.
M. A. E.

The decoloration of glass. GEORG JAECKEL. *Glastech. Ber.* 8, 257–65(1930).—Distinction is made between phys. (Nd, Ni, Co) and chem. (Mn, Ce) decoloration. It is shown that with Fe a change of color can be accomplished only by changing the oxidation state of the Fe. The effects of Mn, Ce, Nd, Co and Ni as decolorizers are presented in a color chart. Se presents difficulties; its use in the form of Zn selenide is suggested. X-ray treatment affects color of Mn and Se glass but not of Ni or Co glass.
M. A. E.

The refining of glass. G. GRUBHOFF, H. KALSING AND M. THOMAS. *Glastech.*

Ber. **8**, 1–24(1930).—"Refining" is defined as the freeing of the glass melt from visible seeds. The efficiency of the following in refining an alkali-lime batch has been investigated: Na_2SO_4; Na_2SO_4 with C; C; Na_2SO_4 with KNO_3; KNO_3; As; As with nitrate; NH_4 salts; alkali chlorides; F compds. The literature on these and other refining materials is surveyed, and a gas-pressure theory of refining developed. A later report will present a quant. comparison of various refining materials. M. A. E.

Influence of the size of the opacifying particles on the form of the dispersion curves of opaque glasses. H. Schoenborn. *Glastech. Ber.* **8**, 280–3(1930).—The size of the opacifying particles dets. the relation between the direct and the total transmission, both in opaque solns. and in technical opaque glasses. M. A. E.

Constituents and advance calculation of soda-borosilicate glasses. Oscar Knapp. *Glastech. Ber.* **8**, 154–8(1930).—The influences of varying the percentages of Na_2O and B_2O_3 on the working qualities and on the coeff. of expansion are presented in tabular form. Comparison is made with calcd. values of the coeff. of expansion. M. A. E.

Investigation on the colloidal nature of cadmium sulfide glass. G. A. Suckstorff. *Glastech. Ber.* **8**, 270–5(1930).—The absorption spectrum and the Tyndall cone were investigated in relation to percentage of coloring material and to temp. in 3 technical CdS glasses. From these expts. S. has concluded that CdS glass is not normally colloidally colored glass. The form of the absorption spectrum is due to various causes. Probably the lack of a sharp limit in the short-wave region is due to destruction of CdS at high temps. M. A. E.

X-ray transmission of some beryllium glasses. C. Gottfried. *Glastech. Ber.* **8**, 283–5(1930).—Values calcd. from the compn. are compared with observed values for 22 glasses which contain varying percentages of Si, Be, Al, Ca, Mg, Na and O. M. A. E.

Determination of the state of oxidation of iron and manganese in glass. Franz Salaquarda. *Glastech. Ber.* **8**, 265–70(1930).—Various quant. procedures are given. The independence of color in respect to Fe_2O_3 content is discussed. The formation of the higher Mn oxide depends on oxidizing conditions during melting. When both Fe and Mn are present, MnO_2 gives off O during the melting and remains in the glass as MnO. M. A. E.

Influence of moisture in sand on the mixing of the glass batch. I. I. Kitaigorodski and Ya. A. Shkolnikov. *Keram i Steklo* **6**, 415–9(1930).—The results of tests showed that a min. quantity of moisture of 0.2 to 1.3%, depending on the kind of sand used, greatly increased the homogeneity of the batch. The permissible max. was 3.5%. M. V. Kondoidy

Ancient Chinese chemical industries. V. Pottery. J. P. Li. *Chem. Ind* (China) [2], **5**, 43–57(1930).—A review. Wm. H. Adolph

Measurement of the plasticity of clays. G. W. Scott Blair. *J. Phys. Chem.* **35**, 374–82(1930).—When different clay pastes are compared at the same concns., it is found that the mobilities and yield values depend upon the hydration capacity rather than upon the plasticity. For clays flowing under low shearing stresses there is a critical shearing stress which is closely related to the plasticity of the clay. Electrolyte mixts. contg. both a coagulant and a peptizer increase plasticity. S. B. S.

Simple method for determining the refractoriness of clay. P. A. Zemyatchenskii and F. A. Zenkovich. *Trans. Ceram. Research Inst* (Moscow) No. **24**, 1–29(1930).—Clays were pulverized, mixed into a paste and molded into cones. When the clay samples did not fuse, fluxes were added, and relative refractoriness was thus obtained. Fe_2O_3 and CaO, which do not produce a eutectic, proved to be the best fluxes. Tables were compiled from which the fusing points could be detd. M. V. Kondoidy

Velocity of temperature increase in testing deformation [of refractory clays]. V. Zegshda. *Trans. Ceram. Research Inst.* (Moscow) No. **24**, 66–73(1930).—The rate of heating greatly affected results and must not exceed 5° per min. M. V. K.

Report on red roofing tile. W. Emery. *Brit. Clayworker* **39**, 351–7(1930).—Water smoking consumes 82% of the firing time but only 17% of the fuel. R. A. H.

Russian and Slovakian magnesite. E. Dworzak. *Feuerfest Ofenbau* **6**, 145–50 (1930).—Chem. analysis and mech. testing of Russian and Slovakian brick show that the former contains 10% more MgO (*i. e.*, 92%), has a higher softening point, impact resistance and porosity, shows less sintering and brittleness, and has a lower sp. gr. They have the same slag resistance. Granular refractories from both sources have the same sintering properties. The best size to use is 5 mm. or smaller. Anything larger requires the addn. of fines. Steel works may increase sintering of Russian material by adding up to 15% Martin slag of 5-mm. diam. B. A. Soule

Mullite formations in ceramic bodies. L. SOLODOVNIKOVA. *Trans. Ceram. Research Inst.* (Moscow) No. 25, 45–56(1930).—By microscopical investigations of different ceramic bodies, S. found mullite formations, the size and quantity of which depend on the temp., duration of firing and porosity. The investigation of a porcelain tube of a thermo element subjected to a temp. of 1600° showed the body changed into a vitrified ground mass with mullite as needle crystals. Their prism angle was 89°26′; $n_g = 1.655$ and $n_p = 1.643$; double refraction = 0.125; $2V = +49°30'$. An old glass-melting pot showed crystalline mullite needles with n of 1.64 to 1.65 and a double refraction of about 0.012. Several kaolin cones, grog pieces and mixts. of kaolin and Al_2O_3 were also studied. M. V. KONDOIDY

The milling of pottery materials. LEONARD ANDREWS. *Pottery Gaz.* 55, 1891–7 (1930). R. A. HEINDL

Nepheline cyanite and nepheline apatite in porcelain industry. V. M. PERMYAKOV. *Keram. i Steklo* 6, 456(1930).—P. discusses the possibilities of using nepheline cyanite and nepheline apatite instead of feldspar in the porcelain and faïence industries, although these minerals are rich in Fe_2O_3 (5 to 6%). Investigations showed that by lowering the Fe_2O_3 content to 0.7 to 0.9% the nepheline cyanite and nepheline apatite, whose deposits are very large in U. S. S. R., can be used with success instead of feldspar. M. V. KONDOIDY

Kaolin as a raw material for refractories. E. KÖHLER. *Trans. Ceram. Research Inst.* (Moscow) No. 25, 1–44(1930).—The testing materials were prepd. from 50% raw kaolin and 50% grog which was fired to 1200°, 1250° and 1600°. The compn. and properties of the materials used are tabulated. The samples were fired to 1200°, 1350°, 1600° and 1750° and tested. The refractoriness of all kaolins was Cone 36. A special app. used for detg. deformation showed, that by firing to high temps., it is possible to prepare very resistant products which show no deformation with 2 kg./sq. cm. pressure at temps. over 1550°. Kaolin is a valuable raw material for refractories. M. V. KONDOIDY

Effect of gases from bagasse and coffee hull fuels on boiler masonry. F. W. FREISE. *Feuerfest Ofenbau* 6, 150–2(1930).—Tests of some 20 materials for boiler masonry where the fuel is high in K_2O (bagasse 34.66%, coffee hulls 45.15%) indicate that acid refractories are strongly attacked. Masonry for boilers on heavy duty should contain over 60% Al_2O_3. Tables of compn., properties and reactions of materials tested are given. B. A. SOULE

Specifications for tank blocks. W. J. REES. *Pottery Gaz.* 55, 1898–901(1930). R. A. HEINDL

Discovery of boric acid in the glazes of Aretine vases. R. NASINI. *Compt. rend.* 191, 903–5; *Nature* 126, 877–8(1930).—With the assistance of R. Grassini, N. has definitely established the fact that H_3BO_3 is a constituent of the glazes on vases excavated at Arezzo. J. H. MOORE

Glazes without lead. O. V. CHEREPOV. *Keram. i Steklo* 6, 537–8(1930).—The compn. of these glazes for earthenware is tabulated. Glazes contg. MgO were best; they had a smooth, lustrous surface, and did not affect the quality of the colors under the glaze. M. V. KONDOIDY

Glass. DEUTSCHE VERBAND DER FLASCHENFABRIKEN G. M. B. H. Ger. 510,944, June 23, 1926. A device for placing molten glass at the bottom of the glass mold is described.

Apparatus for feeding mold charges of molten glass. THEODORE C. STEIMER (to Hartford-Empire Co.). U. S. 1,788,413, Jan. 13. Structural features.

Apparatus for feeding mold charges of molten glass. LAX & SHAW, LTD., J. E. BRANFORD and J. F. SHAW. Brit. 334,213, May 29, 1929. Structural features.

Apparatus for feeding mold charges of molten glass. C. H. RANKIN and RANKIN AUTOMATIC GLASS FEEDER CO., LTD. Brit. 334,560, March 6, 1929. Various details of construction and operation are described.

Apparatus and mechanical operations for forming molded and blown glass articles. UNITED GLASS BOTTLE MANUFACTURERS, LTD., and T. C. MOORSHEAD. Brit. 334,586, June 6, 1929.

Apparatus for making blown glass articles such as bottles. W. L. VAN NESS (to Corning Glass Works). Brit. 334,453, Dec. 18, 1928. Numerous details of construction and operation are described.

Blowing hollow glassware such as bottles. A. C. FORSTER. Brit. 334,186, May 27, 1929. App. and various details of operations are described.

Apparatus for shaping glass tubing. GEORGE A. MILLAR (to General Electric Vapor Lamp Co.). U. S. 1,788,926, Jan. 13. Structural features of an app. adapted for making switch-body bulbs, etc. U. S. 1,788,927 also relates to app. suitable for working hollow glass articles.

Apparatus for splicing hollow glassware such as tubes and bulbs. ROY D. MAILEY and WILFORD J. WINNINGHOFF (to General Electric Vapor Lamp Co.). U. S. 1,788,954, Jan. 13. Structural features.

Water-cooled casting table for forming and rolling glass plates or sheets. Y. BRANCART. Brit. 334,488, Feb. 21, 1929. Structural features.

Apparatus for sheet-glass production. NESTOR MAMBOURG (to Libbey-Owens-Ford Glass Co). U. S. 1,788,923, Jan. 13. Structural features.

Cooling glass plates. N.-V. MIJ. TOT BEHEER EN EXPLOIT VAN OCTROOIEN. Ger. 510,506, June 4, 1927.

Protecting glassware from the attack by hydrofluoric acid. N. F. ZHIROV. Russ. 51,673, May 24, 1929. Glassware is protected by a layer formed by a mixt. of ceresin, rosin and tar.

Laminated glass sheets (safety glass). A. G. WORRALL (to L. J. Kolb). Brit 334,768, Oct. 30, 1928. App and various details of manuf. are described.

Uniting glass sheets with sheets of pyroxylin composition or the like. LIBBEY OWENS GLASS CO. Brit. 334,378, Aug. 30, 1929. The glass sheets are coated with a mixt. of gelatin, a solvent for the gelatin such as water, a cellulose deriv. such as nitro cellulose and a solvent for the latter such as acetone, and a mutual solvent such as HOAc. Various details and modifications of compns. and procedure are described

Safety glass. HANS KINON. Fr. 688,846, Jan. 25, 1930. The sheets of glass are artificially roughened by chem. or phys. means to create points of adherence for the intermediate layer.

Safety glass. SOC. DES USINES CHIM RHÔNE-POULENC. Fr. 688,884, April 1929. Safety glass is made by joining sheets of glass covered with an appropriate adhesive with a sheet of plastic material at ordinary temp. The process takes place in a bath composed of a volatile liquid, which is a non-solvent for the plastic material in the cold and a solvent when hot; afterward pressure is applied in a heated autoclave.

Safety glass. SOC. DES USINES CHIM. RHÔNE-POULENC. Fr. 36,863, May 4, 1929 Addn. to 658,563 (*C. A.* **23**, 5291). The assembled sheets after removal from the bath described in Fr. 658,563 are submitted to a light pressure of short duration and placed in an autoclave contg. a gaseous fluid under pressure and preferably above ordinary temp.

Glass-making furnace. LA TECHNIQUE VERRIÈRE (SOC. ANON. FRANÇAISE) Fr 689,276, Feb. 3, 1930.

Open-hearth glass-melting furnace. A. V. GRUM-GRZHUIMAILO. Russ. 7217, Mar. 16, 1926. Constructional details.

Furnace for annealing glass objects. JACQUES CHAUDRON. Fr. 689,898, April 10, 1929.

Annealing furnace for glass products. THEODOR TEISEN. Fr. 690,155, Feb. 1930.

Chamotte-, Dinas- and similar bricks. ROBERT AUGUSTIN. Ger. 510,556, June 21, 1928. The dry or half-dry molded bricks are subjected to pressure, wetted and again pressed.

Device for filling the hollow separating walls of ceramic kilns with sand. BORKESSEL & CO. M. B. H. Ger. 510,872, Nov. 29, 1928.

Gravity-feed tunnel kiln suitable for burning ceramic products. TAINE G. McDOUGAL (to A C Spark Plug Co.). U. S. 1,788,885, Jan. 13.

Drier for ceramic products. JEAN RAPPOLD. Fr. 690,627, May 6, 1929.

Chamber drier for tiles, etc., arranged directly above the annular kiln. JULIUSZ JANASZEWSKI Ger. 510,050, Aug. 28, 1928.

Tunnel furnace for baking porcelain, etc. RENÉ M. D'ARLEUX and ÉMILE VIOLETTE. Fr. 36,615, Mar. 30, 1929. Addn. to 593,695.

Making ceramic nozzle plates for artificial fibers. FIRMA CARL ZEISS. Ger. 510,069, Jan. 25, 1925. Manipulative features are described.

Vitrified stone ware. GEWERKSCHAFT WESTEND. Ger. 510,700, April 7, 1927. Finely ground chamotte or brick dust is mixed with clay to form the ware, and the plasticity is diminished by adding chamotte or brick dust previously heated to glowing at 900–1000°. The ware is then vitrified at 1250–1280°.

Making quartz objects. LA SOCIÉTÉ QUARTZ & SILICE. Ger. 510,507, Feb. 16, 1927. The parts of the object are made separately of quartz and then heated *in situ* till they become plastic and stick together.

Fused silica. W. GLEICHMANN. Brit. 334,720, Sept. 20, 1929. For obtaining fused silica free from bubbles, pieces of rock crystal, which have been preheated to about 600°, are fed into the flame of an O-H blowpipe so that they are projected by the flame against a surface where they gather to form a fused mass. App. is described.

Refractory objects. MARCEL FOURMENT. Fr. 36,973, Mar. 14, 1929. Addn. to 638,843 (*C. A.* **23**, 495). In heating refractory materials as described in the prior case, the conducting piece serving as heating element inside the refractory material is made of a substance having a m. p. near the baking temp., so that at the end of the operation it may be melted and poured away.

Blocks for lining furnaces. RAYMOND C. BENNER and GEORGE J. EASTER (to Carborundum Co.). U. S. 1,789,131, Jan. 13. Blocks of refractory material such as SiC or graphite are pressed in a direction perpendicular to the plane of the exposed faces of the blocks in order to lessen their permeability.

Enamels. SOC. INDUSTRIELLE DE FUSION, RECHERCHES ET APPLICATIONS DU QUARTZ. Fr. 689,742, Feb. 12, 1930. Quartz or silica glass is used as a support for enamels.

Enamel coatings. OSCAR HOMMEL. Fr. 688,994, Jan. 28, 1930. Metallic objects are coated with a layer of an oxide of a metal of the Fe group before coating with enamel.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Electrofused cement. M. KAUCHTSCHISCHWILI. *Siemens-Z.* **10**, 536–41, 560–2 (1930).—Alumina cement possesses numerous known advantages over the best portland cement. The chem. compn., properties, uses and advantages are discussed. The elec. fusion process is most suitable for the prepn. of a uniform product. A high yield is obtained with an elec. arc tapping furnace which may be operated continuously or intermittently. An elec. furnace designed and installed by Siemens and Halske A.-G. for the manuf. of alumina cement is described. The furnace is built for multi-phase current operation and is provided with 3 C electrodes arranged in a triangle. A special masonry is used to protect the bottom, and the walls are water-cooled. Production and efficiency are increased by the use of continuous electrodes. The raw materials, alumina, lime, iron oxide and SiO_2, are crushed, mixed and introduced into the furnace, the bauxite having been previously heated at 800° to remove moisture. Since the m. p. of the molten mixt. is relatively low, 1400°, over-heating must be prevented to reduce objectionable side reactions and vaporization loss. This may be accomplished by use of electrodes of large cross section, small c. d., relatively high arc tension, and large bath surface. The fluid cement is tapped from 2 holes into cast-iron troughs of 275 to 325 kg. capacity, after which it is treated in the usual manner for cement klinker. For each ton of cement are required 0.7–0.8 ton of bauxite, 0.4–0.45 ton of calcined lime, 700–800 kw. hrs. and 7–8 kg. of electrodes. ALLEN S. SMITH

Concrete control saves cement, yields high strengths and speeds work. ERNEST A. HAGY AND CHARLES T. KENNEDY. *Eng. News-Record* 105, 850–2(1930).—A brief description of the system of concrete control employed during construction of the Carew Tower Building, Cincinnati, involving the placing of approx. 40,000 cu. yd. of concrete. The results demonstrate that the water-cement ratio law applies in the field of building construction, and that intelligent design and rigorous control can be depended upon to produce uniform high-strength concrete with increased workability and decreased cost of materials and labor. Forms were removed in 3–4 days.

R. E. THOMPSON

Overheating of aggregates found detrimental to concrete. Wm. H. Bachelder. *Eng. News-Record* **105**, 973(1930).—Strength and flow tests on concrete prepd. with aggregates and mixing water heated to give batch temps. of 70°, 100° and 130°F. when discharged from the mixer are shown graphically. Measuring workability by flow, 5.7 gal. of water per sack of cement was required for 70° concrete, 6.07 gal. for 100° concrete and 6.85 gal. for 130° concrete to obtain the same workability when using a 1:2.07:3.12 mix by wt. Strength tests indicated that concrete placed at 130° loses approx. 20% of its strength and that less than half the loss in strength is due to the higher water-cement ratio. No attempt was made to prevent loss of heat after concrete was placed. Tests for water content indicated that about $^1/_6$ of the addnl. water used in the 100° concrete and about $^1/_4$ of that used in the 130° concrete were lost before the concrete was tamped. As would be expected, the time of setting was reduced by heating the mix. R. E. T.

The preparation of a new road binder. C. F. Broadhead. *Gas World* **93**, 298 (1930).—A reply to Broadhead (*C. A.* **24**, 4912). New data are submitted on the ultramicroscopic C particle no. of distd. tar and "Bitural." For distd. tar the C particle count per cc. was found to be 4×10^8 and for "Bitural" 17×10^8. It is claimed that the higher C particle no. of "Bitural" is indicative of its superiority as a road tar.

F. H. Bergeim

Asphaltic bitumen and its use in breweries. L. Aerts. *Bull. assoc. étudiants école sup. brasserie univ. Louvain* **30**, 106–10(1930).—A brief outline of the uses of asphalt in the building industry, more particularly as regards its applications in the brewing industry. A. Papineau-Couture

Manufacture of portland cement and cupriferous Fe from slag (Bradbury) 9. Fireproofing wood, etc. (Brit. pat 334,408) 18. Cement. Antoni Eiger. Swiss 137,693, Feb. 11, 1929. See Austrian 115,702 (*C. A.* **24**, 2265).

Cement. Soc. des ciments portland artificiels de Couzon. Fr. 690,021, Feb. 15, 1930. An artificial portland cement is made from a primary material composed of a single deposit of sedimentary origin, contg. in mixt. the essential elements of cement but in disproportionate amts. The elements are sepd. by heating the mixt. to a temp. below that at which they combine, grinding, whereby the lime elements are reduced to a finer powder than the hard siliceous elements, and sifting.

Grinding mill and associated cooling chambers suitable for use in cement manufacture. Lionel D. Parker (to Vickers-Armstrongs, Ltd.). U. S. 1,789,021, Jan 13 Structural features.

Apparatus for partial dehydration of cement mud before its admission into the rotary kiln. A. A. Vorobyev. Russ. 62,191, Jan. 11, 1930.

Rotary cement kiln. A. A. Vorobyev. Russ. 63,537, Feb. 1, 1930.

Rotary kiln for making fusible cement, with means for separately preheating the ingredients. Studienges. zur Bauxitverwertung G. m. b. H. Ger. 510,049, Sept. 25, 1929.

Asbestos-cement tiles. Waagtaler Syenit Asbest Schieferfabrik A.-G. Ger.

510,787, Feb. 25, 1928. A dry cement dye mix is scattered on the tiles, which are to be colored on one side, and sucked into the material by a vacuum app.

Device for removing rolled asbestos-cement tubes while still plastic. KARL HERZOG. Ger. 510,550, Sept. 23, 1928.

Aluminous cement castings. SPERANZA SEAILLES and JEAN SEAILLES (to Alfred P. Bourquardez). U. S. 1,789,197, Jan. 13. Castings having a polished translucent surface are formed of aluminous cement contg. less than 1.5% of Fe.

Concrete. RÖCHLINGSCHE EISEN- UND STAHLWERKE A.-G. Fr. 689,363, Feb. 3, 1930. Blast-furnace dust, from the treatment of minette either alone or mixed with fine ores in the furnace, is concreted by mixing it with lime-contg. substances such as converter waste, slaked lime or the equiv.

Concrete pipes. ALPHONS HORTEN. U S. 1,788,718, Jan. 13. A plastic cement compn. is formed around a heated tapered hollow core formed with an enlarged portion at the end of larger diam., and is allowed to set first in air and then in hot water. A cooling medium is circulated through the core while continuing the heating of the set plastic material, in order to facilitate sepn. of the core from the concrete pipe.

Concrete piles. AUGUST E. SCHUTTE. U. S. 1,788,748, Jan. 13. After forming a concrete pile, it is surrounded (before setting) with an adherent coating comprising a mixt. of portland cement "grout" and asphalt.

Monolithic concrete paving slabs. BERTRAND H. WAIT. U. S. 1,788,785, Jan. 13. Structural features.

Paving material. WM. T. RAGLAND. U. S. 1,788,887, Jan. 13. A substantially liquid binder such as heated mineral pitch is placed in a mixing app.; there is then blown into the app. in diffused and scattered condition the different grades of aggregate; and the materials are agitated upon the introduction of each grade of aggregate. Cf. *C. A.* **24**, 5129.

Bituminous paving compositions. E. C. WALLACE. Brit. 334,588, June 6, 1929. See U S. 1,749,651 (*C. A.* **24**, 2267).

Bituminous paving material. SOUTH METROPOLITAN GAS CO. and H. PICKARD. Brit. 334,336, July 23, 1929 A material suitable for spreading while hot on a road foundation comprises coal 18–25% dispersed in tar (which may be admixed with not exceeding 25% its wt. of pitch), and hard stone of size between about 1 cm. down to dust. Various details of prepg. the mixt. are given.

Artificial stone. ROBERT KUNZ. Ger. 512,467, Nov. 27, 1928. In the manuf. of plates from fibrous material and a hydraulic binder, a small quantity of an oil or fat, particularly mineral oil, is added at any convenient stage. Breakage under the action of heat is thus avoided.

Artificial stone resembling travertine. JOHN A. RICE (to Bubblestone Co.). U. S. 1,788,592, Jan. 13. A stiff foam formed by beating a mixt. of casein and rosin is distributed through a cementitious material and the latter is then allowed to set.

Treating stones. JOSEPH GIOVANNINI. Fr. 688,990, Jan. 28, 1930. Stones are given the appearance of marble by heating them in a furnace to about 250°, then putting them into an aq. soln. of a salt such as a metallic sulfate, NaCl, alum, borax or $MgCO_3$ and polishing.

Imitation marble slab or the like. NATHAN E. NEWMAN. U. S. 1,789,111, Jan. 13. An asbestos slab is dried, immersed in a waterproofing bath such as a vegetable oil and naphtha and, after being permitted to dry, is treated with a filler and with a coating of lacquer; the lacquered surface is rendered smooth and there is transferred to it by a photogravure process a facsimile marble pattern; over this is placed a coating such as lacquer and the coating is highly polished.

Cellular blocks, etc. SOC. LORRAINE DES ACIÉRIES DE ROMBAS. Fr. 690,045, Feb. 15, 1930. Cellular agglomerates which may be made in the shape of blocks, etc., are made by mixing the sand obtained by granulating blast-furnace slag with cement obtained from slag.

Antiweathering agent. WALTER GURNIK. Ger. 510,871, May 12, 1929. An antiweathering agent for coating building materials, especially cement, consists of a mixt. of Euphorbiaceae oil and resin hardened with $ZnCrO_4$. Color may be added. The example mentions 38 parts resin melted with 1.9 parts $ZnCrO_4$ with 32 parts oil of *Dryandria cordata* and boiled linseed oil, and 30 parts drying material.

Stucco or plaster. LOUIS E. CHASSEVENT. Ger. 510,699, May 16, 1926. Plaster, etc., is made by stirring gypsum with warm water so that the temp. of the mixt. is maintained above 60°.

Plaster of Paris. OTTO RICHTER. Ger. 512,325, July 24, 1929. A mortar from

which hard, weather-resistant objects can be made is prepd. by mixing gypsum with water and $Al(OAc)_3$.

Artificially colored materials such as granulated blast-furnace slag for surfacing roofing, etc. HAROLD L. LEVIN (to Patent and Licensing Corp.). U. S. 1,788,625, Jan. 13. Granules of blast-furnace slag are provided with a coloring formed *in situ* (suitably by heating with $FeSO_4$ or dichromates) and fused onto the surfaces by a sintering together of the microscopic projections on the surfaces, without vitrification of the surface texture.

Material suitable for roofing, insulating, etc. ALBERT C. FISCHER (to Philip Carey Mfg. Co.). U. S. 1,789,284, Jan. 13. Material such as roofing felt is satd. with an oil and coated with a bituminous compn. or other suitable mastic of lasting adhesiveness which is sticky to the touch. U. S. 1,789,285 relates to generally similar material satd with a drying oil such as China wood oil (which may be used with a non-drying oil also). U. S. 1,789,286 relates to generally similar material satd. with a mixt of bituminous material such as pitch or gilsonite and a non-drying oil such as castor oil. U. S. 1,789,287 describes a similar product which may be formed of felt or paper satd. with waterproofing material such as a suitable oil and coated with a sticky bituminous material such as a tacky road oil together with resin, castor oil and rubber, "mineral rubber" or a varnish gum. Cf. *C. A.* **24**, 4609.

Artificial wood. MARC J. A. A. LEFRANCQ. Fr. 691,311, May 16, 1929. Waste wood with the addn. of 1–3% of a siccative such as MnO_2 and 2–8% of a drying oil is molded under pressure and heat.

Preserving wood. I. G. FARBENIND. A. G. Fr. 36,639, Jan. 26, 1929. Addn. to 663,356. Mercurized aliphatic hydrocarbons such as mercurized ethyl bromide are used for preserving wood.

Wood impregnation. I. G. FARBENIND. A.-G. Brit. 334,202, May 28, 1929. Salts or salt-like compds. are used such as those formed from 2,4-dinitrophenol, 3,5-dinitro-2-hydroxy-1-methylbenzene or like nitrated phenols and hydroxyalkylamines such as mono- and di-hydroxyethylaniline, mono-, di- and tri-hydroxyethylamine and the corresponding hydroxypropylamines. Other preservatives, fungicides, etc., may be conjointly used.

Impregnating wood with a bituminous composition. A. V. GRIDNEV. Russ. 54,827, Sept. 17, 1929. The wood is placed in a container charged with about 27 parts by wt. of Syrian asphalt and 5 parts blown linseed oil dissolved in 68 parts C_6H_6. The temp. is then raised to 50–60° and the pressure to about 3–4 atm.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

The rational processing of fuels. HECTOR HARDY. *Bull. soc. belge. ing. ind* 10, 623–63(1930).—A dissertation on the principles of fuel preparation in which the applications of coal washing, flotation, briquetting, high- and low-temperature carbonization and solvent treatment are discussed. H. L. OLIN

Sulfur in motor fuels. GIORGIO ROBERTI. *Atti III congresso naz. chim pura applicata* 1930, 540–6.—The S content of motor fuels in various countries is shown, as well as the corrosive action of high S content on motor cylinders. Methods of S removal in refining are reviewed. E. M. SYMMES

New ways for recovery and application of coal. H. A. J. PIETERS. *Chem. Weekblad* **27**, 542–6(1930).—A short review. B. J. C. VAN DER HOEVEN

The Jharia coal field. C. S. FOX. *Memoirs Geol. Survey India* **56**, 255 pp.(1930). F. gives a thorough discussion of the geology of this area (125 pp.) and of the coal reserves (65 pp.). Natural coke occurs in the regions intruded by igneous rocks. Workable coal seams occur in 6 of the 12 stages into which the Damuda group of sediments have been sub-divided in this field. Typical analyses of coal from each of the 6 stages, Telmucha, Murulidih, Bhagaband, Jialgora, Caleira and Muraidih are, resp.: moisture 2.11, 2.20, 1.80, 1.59, 0.70, 0.65; volatile matter 28.40, 27.68, 28.80, 24.00, 18.75, 14.20; fixed C 52.80, 57.20, 59.30, 62.40, 63.05, 68.00; ash 18.80, 15.12, 11.09, 13.60, 18.20, 17.8%; and calorific value 6607, 7403, 7209, 7403, 6882 and 7141. In addn. 122 other analyses are tabulated. Details of grading and classification of coal by the Indian Coal Grading Board are given. Reserves in millions of tons are: to 500 ft.—1707; to 1000 ft.—3122; to 2000 ft.—4237. Good coking coal (to 1000 ft.) reserves are 800 million tons. ALDEN H. EMERY

The proposed British standard specification for the sampling and analysis of coal. R. LESSING. *Gas World* 93, 440–1(1930).—A discussion. F. H. BERGEIM

The plastometer. A new instrument for measuring the plastic properties of coal. JOSEPH D. DAVIS. *Ind. Eng. Chem., Anal. Ed.* 3, 43–5(1931).—The app. is described and tests on a few coking coals are given. J. H. MOORE

Combustion tests with Illinois coals. ALONZO P. KRATZ AND WILBUR J. WOODRUFF. Univ. Ill. Eng. Expt. Sta., *Bull.* No. 313, 58 pp.(1930).—This report covers the results of an investigation of Illinois coals from La Salle, Peoria, Franklin and Williamson counties, undertaken to compare their performance characteristics as detd. by their influence on the overall efficiency, temp. of the flue gases, combustion rate and draft required when the boiler unit was operated at given steaming capacities; and to study the incidental factors, such as excess air and ash-pit and flue-gas losses, as influenced by the phys. and chem. characteristics of the coals. The boiler employed was a B and W unit of 5080 sq. ft. heating surface, designed to operate at 160 lb. and equipped with a chain grate stoker with flat suspended ignition arch, natural draft being used. Results showed (1) that av. overall efficiencies based on all tests were 62.9% for the northern coals and 65.6% for the southern; (2) that the max. attainable capacity with the furnace used varied inversely as the ratio of volatile matter to fixed C in the coal; (3) that the setting must be high to permit the combustion of Illinois coals without loss due to unburned hydrocarbons; (4) that the Williamson and the Peoria county coals displayed a tendency to coke at low loads, resulting in ash-pit loss on the chain grate, while those from Franklin and La Salle counties were non-coking; (5) that draft requirements were not materially different for the 4 coals but that the use of sized coals resulted in higher capacities than were possible with unsized fuel. H. L. OLIN

Nature of bitumens from coal. G. STADNIKOV AND R. WAHNER. *Brennstoff-Chem.* 12, 23–5(1931).—Bitumen extd. by a C_6H_6-C_2H_5OH mixt. at atm. pressure following HCl treatment of coal, already extd. with C_6H_6-C_2H_5OH in a Soxhlet app. (bitumen A) and C_6H_6 under pressure (bitumen B), has been named bitumen C. These 3 bitumens extd. from the various layers of the Chachareisky, the Tscheremchorsky and the Schilkinsky deposits have been completely examd. Comparative data are tabulated for yields, m. p., acid, sapon. and I nos., and C and H contents. Bitumen is a product of the decompn. at extn. temps. of org. acids; CO_2 seps. in the depolymerization. F. W. JUNG

The influence of inorganic constituents in the carbonization and gasification of coal: the liberation of ammonia. A. H. EASTWOOD. *Gas J.* 192, 745(1930).—The tests were carried out on a fusible coal contg. 1% ash. Lime, $CaCO_3$ and Fe oxide were added in amts 5% by wt. of the coal and the mixts. were carbonized in atms. of N_2, H_2 and steam N_2 contg. 60% steam. The time of carbonization was 9 hrs., the temp. being advanced in stages of 100° from 200° to 1000°. With coal alone NH_3 evolution commences at 300° and reaches a max. at 700°. In a neutral atm (N_2) carbonization up to 1000° yields 17% of the N of the coal as NH_3. With a H_2 atm. the yield of NH_3 is 33.3%, and with steam and N_2 the yield is 25%. When the inorg. constituents referred to above were added to the coal NH_3 evolution began at 300° in all cases. Lime or $CaCO_3$ raises the NH_3 obtained up to 1600° from 17 to 22% with a N_2 atm. while Fe oxide decreases the yield to 15%. With an atm. of H_2, $CaCO_3$ increases the yield from 33 to 37%. CaO gives a slightly less increase and Fe oxide has no effect. In the presence of steam N_2, CaO raises the yield from 25 to 34%, $CaCO_3$ to 32% and Fe oxide raises it slightly. The mechanism of the effects of the inorg. constituents is discussed. F. H. BERGEIM

Investigation of benzine prepared from brown coal by high-pressure hydrogenation without addition of tar. J. VARGA AND I. MAKRAY. *Brennstoff-Chem.* 12, 21–2(1931).—Eocene brown coal from the Tataer district was hydrogenated in a rotating autoclave, with an initial H pressure of 110 atm., by holding 1–2 min. at 470° As catalyst, 330 g. Fe_2O_3 was used with each charge of 2200 g. pulverized coal. A yield of 440 cc. oil boiling under 230° was obtained per run, 50% of the ash- and moisture-free coal being made sol. in C_6H_6. Six yields of oil, each distd. to 230° from an Fe flask, were combined, dehydrated with fused Na_2SO_4, and twice redistd. to 230° from a Cu flask, giving an oil of d. 0.884 and 21% sol. in 14% alkali. The compn. was: bases (chiefly tertiary) 3.00, phenol 1.58, cresols and higher phenols 19.42, unsatd. compds. 6.60, C_6H_6 0.70, toluene 2.02, xylenes 2.65, other aromatic compds. 6.13, paraffins and hydroaromatic compds. 53.80%; naphthalene was absent. Boiling ranges and gravities are given for the various fractions. F. W. JUNG

The Valdarno lignite industry. The Castelnuovo mine of the Società mineraria del Valdarno. DARIO RAFFO. *Atti III congresso naz. chim. pura applicata* 1930, 163–70.—Descriptive. E. M. SYMMES

Developments in the study of combustibles. MARIO G. LEVI. *Atti III congresso nas. chim. pura applicata* 1930, 171–88.—A review of recent methods of fuel research, with illustrations. E. M. SYMMES

Thermal measuring equipment in the economical operation of gas works. A. GRUNWALD AND W. LIESEGANG. *Siemenschrift* 1930, No. 4–5; *Gas u. Wasserfach* 73, 1170–3(1930).—Various points where temp. or vol. may be measured are mentioned. Resistance thermometers permit distant reading. Mention is made of the Ardometer, which follows the pusher of a coke oven-plant and permits detn. of wall temps. A water-cooled head eliminates radiation effects. Boiler flue gas analyzers for CO_2 and CO + H_2 are mentioned. The article is illustrated. R. W. RYAN

Re-forming natural gas. W. W. ODELL. Bur. Mines, *Tech. Paper* 483, 54 pp. (1930); cf. *C. A.* 24, 710.—When the ignited fuel bed of a water-gas generator is alternately blasted with air and a hydrocarbon gas such as natural gas, the resultant gas is comprised largely of H_2, the remainder being CH_4. C is entrained in the gas and can be recovered. As much as 8 lb. per 1000 cu. ft. of natural gas treated was recovered Operating data and factors influencing the results are given. When the ignited fuel is alternately blasted with air and both steam and natural gas in controlled proportions, re-formed gas is produced substantially without entrained C, the gas consisting of CO, H_2 and lesser CH_4. The thermal efficiency and gas-making capacity are higher in generating re-formed gas in this manner than in making water gas and the fuel used per 1000 cu. ft. of re-formed gas is lower. Operating data and factors influencing results are given. Propane and butane were re-formed in a similar manner with similar results The relative amts. of steam required for various hydrocarbon gases are different. Equations showing this relation are given. By using the re-forming process natural gas can be used during periods of off-peak demand in the generation of city gas having a relatively lower calorific value; the re-formed gas thus made, when enriched with natural gas, has a compn. and a sp. gr. comparable to that of city gas manufd. by other standard methods. ALDEN H. EMERY

Liquefied petroleum gas. O. M. SETRUM. *J. Western Soc. Eng.* 35, 448–65(1930) A story relating how natural gas has been "made portable, put on wheels, as it were, and widely distributed." Many large plants make use of this new means of gas generation and enrichment. The properties of these fuels have been carefully detd. By controlling the mfg. process, by lab. tests and checks and the strict adherence to rigid specifications, products of unusual uniformity are obtained. A brief résumé is tabulated of the characteristic properties of com. propane and com. butane. The liquefied petroleum gases are especially valuable to the gas industry, being readily transported as a liquid and converted into a gas at the utilization point. Utilization is classified into 3 major groups, based on the methods of distribution and application of the liquefied petroleum hydrocarbons, as follows: (1) direct gas service, (*a*) individual domestic distribution in cylinders, (*b*) community distribution in pipe lines, (*c*) industrial use, (2) gas enrichment and cold carburetion, (*a*) enriching water gas, blue gas or other gases of low thermal value to meet calorific standards, (*b*) re-carburetion to offset thermal loss due to compression and transmission of manufd. gas; (3) base material for mfg. gas, (*a*) meeting peak-load conditions, (*b*) reforming to produce a low-gr. gas of high thermal value, (*c*) butane air carburetion, the Philfuels process of gas manuf A diagrammatic flowsheet is shown of a plant using butane to make gas. W. H. B

Carbureted water gas and the influence of temperature on the composition of the tar formed. T. B. GLOVER. *Gas J.* 191, 702–4; 192, 38–42(1930).—Carbureted water gas produced under the usual operating conditions is always satd. with $C_{10}H_8$. When blended with coal gas from vertical retorts the mixed gas has a higher $C_{10}H_8$ content than can be tolerated. Three series of expts. were used in the study of water-gas production: (1) the series detg. the conditions of protective atm. and time of contact, (2) the effect of changing the cracking temp. of the oil on the nature of the products, (3) the effect of the different oil vapor concns. obtained by varying the rate of oil input. The tests were carried out on a Davison Partner generator of 10 ft. 6 in. external diam and having a gas-making capacity of 1½ million cu. ft. per 24 hrs. The gas oil used for the carbureting had the following percent compn.: olefins 17, aromatics 3, paraffins and naphthenes 80 and polycyclic compds. traces. The cracking temps. used were 720°, 740°, 770°, 800°, 820°, giving, resp., tars of the following polycyclic compound content calcd. as $C_{10}H_8$: 14.7, 16.1, 18.9, 21 and 23. The sp. grs. of the tars were 1.060, 1.087, 1.095, 1.090 and 1.120. In another series of tests the temp. was kept const. at 770° and the addn. of oil in gals. per min. was varied as follows: 4.22, 5.88, 7.68. The resp. sp. gr. and polycyclic compd. contents of the resultant tars were 1.425, 1.11, 1.058 and 29.9

26, 21.9. **Distn. tests are given on the tars produced and hydrocarbon group analyses on the distillates.** F. H. BERGEIM

Generation of power from wood waste. OSWALD WANS. *Chem. Age* (London) **23**, 546–7(1930).—A generator suitable for producing fuel gas from wood waste is described. Air is passed freely through a bed of burning wood waste. The issuing gas consists largely of CO and N, with a calorific value of about 155 B. t. u. per cu. ft. The gas generation takes place more freely than with coke, probably because of the lower d. and porous nature of the charcoal. The gas may be used in gas engines or for heating purposes. When used for heating, oxide purifiers are not required because the wood gas is practically free from S compds. The consumption of wood waste is said to be about 2.25 lb. per h. p. hr. with a typical sawmill waste with an av. moisture content of 20–25%. CHANNING W. WILSON

Possible improvements in gas producers. JENS RUDE. *Gas World* **93**, 320 (1930).—The advantage of introducing steam into the producer is treated from a theoretical standpoint. F. H. BERGEIM

Corrosion of cross stream plate air heaters and its prevention. K. BURWICK. *Die Wärme* **53**, 875–7(1930).—It is demonstrated that corrosion of flue gas air heaters must occur if the temp. of the entering air lies essentially below the dew point of the heating flue gas (10° to 15°). A set of curves shows the dew points of flue gases from important fuels. Three processes, with diagrams, are given for preheating the cold air to the dew point temp.: (1) part of the heated air is returned to the intake of the heater; (2) the cold air passes first through a heater warmed by the heated air; and (3) steam or hot water is used. ALLEN S. SMITH

Some experiments on vertical retorts. H. B. KENDRICK. *Gas World* **93**, 571–3 (1930).—In a retort it is contact with highly heated surfaces and not radiant heat that is most active in destroying hydrocarbons. The central core of coal in a vertical retort is the cool zone and the lower coke zone is the hot zone. The gases evolved from the cool zone are richer in hydrocarbons. Approx. 2 vols. of gas are evolved from the hot zone to 1 vol. from the cool zone. Poking during carbonization improves the quality of the gas and lowers the temp. of the exit gas. F. H. BERGEIM

The control of vertical retorts (for continuous carbonization). H. B. KENDRICK. *Gas J.* **190**, 306–9(1930).—Reasons are given for the contention that continuous vertical retorts are more amenable to scientific control than intermittent systems such as horizontal retorts. A Glover-West setting is described. By use of the author's methods of control the thermal yield has been increased to 90%. In operating a vertical retort it is objectionable to attempt to increase the yield and alter the quality of the gas by increasing the vacuum in the gas stream as this loads the gas with inerts, lowers the efficiency of conversion and draws in an excess amt. of air through pores in the setting. A very low vacuum in the heating chamber is desirable. The retort should be kept under a slight pressure. The quality of the gas is best controlled by first adjusting the quantity of steam to the temp. of the retort and making the final adjustment for quality by regulating the throughput of coal. Over-steaming must be guarded against as it may seriously affect the efficiency of the plant. F. H. BERGEIM

The impact hardness, abrasion hardness and reactivity of coke. T. A. MOTT. *Gas World* **93**, Coking Section, 97(1930).—See *C. A.* **24**, 5981. F. H. BERGEIM

The utilization of coke breeze by the Trefois producer. A. L. HOLTEN AND H. C. APPLEBEE. *Gas World* **93**, 340–4(1930).—The Trefois producer installed experimentally has proven satisfactory for the manuf. of producer gas from coke breeze. F. H. BERGEIM

The dry quenching of coke. W. O. RENKIN *Blast Furnace & Steel Plant* **18**, 1803–6(1930).—The Sulzer dry-quenching system is described and illustrated. Dry-quenched coke (through 3-inch or 2-inch screen) stands up better against the standard shatter test than wet-quenched coke. The utilization of the sensible heat to produce steam derives a revenue that in many cases pays for the dry quencher in a very short time. Heat recovery is approx. 1,000,000 B. t. u. per net ton of coke, and an efficiency of 95%. Where the coke ovens are fired with producer gas there is a saving, due to the ability to use dry-quenched coke all through a $^7/_8$ inch screen, and use approx. 25 lb. (11.4 kg.) less of fuel per net ton (909 kg.) produced. Absence of moisture in the extreme coke fines produced makes it more readily mixable with the coal charged to the ovens. The arrangements of several types of plants are indicated. W. H. BOYNTON

Semi-silica versus lime-bonded silica for coke-oven walls. H. D. BENNIE. *Gas World* **93**, Coking Section 113(1930).—Semi-silica bricks have the following properties: (*a*) immunity from spalling, (*b*) permanency of vol. under modern coking conditions, (*c*) sufficient refractoriness under the loads imposed by modern oven design, (*d*) the

min. of thermal reversible expansion, (*e*) the peculiar property of improving in use as regards cond., diffusivity and refractoriness without any accompanying evils.

Fuel. JEAN F. A. BRUZAC. Fr. 689,021, Jan. 28, 1930. A fuel suitable for Diesel engines is made by treating crude petroleum, schist oils, lignite oils, etc., with ozonized air or ozone, washing with a 2% NaOH soln and distg. Gasoline is first distd and then an oil of gas-oil type which is the product desired.

Synthetic fuels. JACQUES LOUIS FOHLEN Fr. 37,076, Dec 23, 1927. Addn to 631,927. The carbonaceous materials used for the reduction of an ore on the one hand and the manuf. of synthetic liquid fuels on the other are present in higher percentage than in a simple metallurgical operation. The yield in liquid fuels is increased by using a high speed of ascending gases with respect to the speed of the descending solids.

Pulverulent fuel for internal-combustion engines. RUDOLF PAWLIKOWSKI Ger 510,311, May 11, 1927. The pulverulent fuel, *e. g.*, coal, lignite, peat, or coke, is freed from low-melting mineral constituents by treating with acid and washing. If the removal of such constituents is not complete, reagents may be added to convert them into difficultly fusible compds. Details of the grinding, washing and drying processes are described.

Liquid fuels. COMPAGNIE INTERNATIONALE POUR LA FABRICATION DES ESSENCES ET PÉTROLES. Fr. 691,172, May 15, 1929. Liquid fuels comprising light hydrocarbon mixts. are prepd. by distg. carbonaceous materials at low temp., purifying and enriching the product with H in the presence of a catalyst, and further hydrogenating the gaseous products of this process. The distillate is again distd. to give light and medium oils, the latter being cracked to give further light oils, the whole of these light oils being vaporized and the vapors returned to the main gas stream.

Motor fuels. JEAN H DE LIGNAC. Fr. 36,884, Feb. 5, 1929. Addn to 679,101 (*C. A.* **24,** 3632). About 20% by vol. of water is added to crude benzene, and the mixt is distd. The benzene is sepd. from the water which retains the impurities.

Treatment of carbonaceous materials. WILLARD C. ASBURY (to The Standard Oil Development Co.). Can. 307,956, Jan. 20, 1931. Carbonaceous material, solid at normal temp., is converted to hydrocarbon oils by grinding and making it into a fluent mass with hydrocarbon oil, subjecting the mass to treatment with a gas rich in H under conditions for hydrogenation, allowing the mass to settle, withdrawing a suspension of solid material in oil and withdrawing oil substantially free of solid material.

Distillates from carbonaceous materials. ROBERT P RUSSELL (to The Standard Oil Development Co.). Can. 307,957, Jan. 20, 1931. Finely divided, solid carbonaceous material suspended in heavy hydrocarbon oil is maintained at an elevated temp. under high pressure in contact with a gas rich in free H, a part of the suspension is withdrawn, and the pressure on the part withdrawn is reduced, whereby a substantial part of the hydrocarbon liquid is vaporized. The vapor is separately condensed.

Oven for the low-temperature distillation of finely granular fuels. METALLGES A.-G. Ger. 512,220, Aug. 17, 1928.

Apparatus for low-temperature carbonization of bituminous material. I. G. FAR-

BENIND. A.-G. Brit. 334,443, Nov. 6, 1929. In app. of the general character described in Brit. 306,723 (*C. A.* **23**, 5313), in which the material is passed through a bundle of tubes in which it is internally heated, each tube is made to taper from the inlet end to the discharge end.

Coal agglomerates. PAOUL GHEZZI. Fr. 689,796, Feb. 12, 1930. Coal is agglomerated with sulfite cellulose liquor to which slaked fat lime or black fused cement is added.

Grading sieve for large and small coal. PAUL DURST and PETER COLLAS. Ger. 510,796, Sept. 21, 1928.

Washing and classifying device for coal and ores. CLÉMENT CLOUWEZ. Ger. 512,317, Mar. 26, 1925.

Sand separator for coal dust. ZEITZER EISENGIESSEREI UND MASCHINENBAU A.-G. Ger. 510,702, July 17, 1928. Addn. to 507,771 (*C. A.* **25**, 799).

Separating mixtures of coal and oil. I. G. FARBENIND A.-G. Fr. 689,274, Feb. 3, 1930. Oils are sepd. from mixts. of oil and coal, particularly residues from hydrogenation of coal, tars, etc., by filtering them in a fluid state at a high temp. through a layer of filtering material or screen, and eliminating the rest of the oil by distn., extn. or emulsification. The distn. is preferably carried out on the filter in such a way that the vapors pass through the filter.

Dehydrating coal, etc. I. G. FARBENIND. A.-G. Fr. 36,611, Mar. 28, 1929. Addn. to 669,519 (*C. A.* **24**, 1961). The process of the prior case in which water is eliminated from carbonaceous material by distn. in the presence of solvents, is applied to the drying of coal, peat, etc., which are to be treated with H under pressure for conversion to valuable products.

Apparatus for carbonizing coal. AMERICAN ENGINEERING CO. Fr. 688,739, Jan. 23, 1930. The coal is heated and distd. to a state of semi-coke. The semi-coke is burnt in a suitably adapted furnace and the combustion gases are used for drying, pre-heating and distg. the coal.

Apparatus for carbonizing coal, schists, etc., at low temperature and for the treatment of ores. JOHN E. HACKFORD. Fr. 690,502, Feb. 24, 1930.

Hydrogenation of coal. ALFRED MENTZEL. Fr. 689,386, Feb. 4, 1930. Coal is hydrogenated for the production of liquid hydrocarbons in layers of not more than 5 mm. thickness and in contact with catalysts by hydrogenating gases. The coal may be caused to travel over a surface which may itself form the catalyst.

Hydrogenating coal and similar materials. A. MENTZEL. Brit. 334,389, Oct. 12, 1928. Coal or the like, in granular form, is subjected, in thin layers not exceeding 5 mm. in thickness, to the action of hydrogenating gases in the presence of catalysts, and preferably so that the gas stream employed effects loosening and movement of the granular particles under treatment. Various details of procedure are described.

Hydrogenation processes. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Fr. 691,303, Mar. 6, 1930. Valuable products such as oils, etc., are obtained by heating coal, lignite, tar, mineral oils and their derivs., cellulose, wood, etc., under pressure with H in the presence of a catalyst composed of a mixt. of 2 or more metals or metallic compds., *e. g.*, metal oxides or hydrates. Thus a mixt. of oxides of Fe and Al contg. water or not may be used.

Briquetting fine coal or semi-coke. GUSTAV HILGER. Ger. 510,807, June 10, 1928. Addn. to 437,528. Details of the app. are given.

Apparatus for determining the melting point of materials such as coal ash. GERRIT A. DEGRAAF (to Eimer & Amend). U. S. 1,789,098, Jan. 13. An app. is arranged for electrically heating a specimen while carried on a support in a controlled atm. and while under observation through a pyrometer and magnifier, both of which are focussed on the specimen.

Montan wax. I. G. FARBENIND. A.-G. (Wilhelm Pungs and Michael Jahrstorfer, inventors). Ger. 510,485, Feb. 18, 1927. Crude or deresinified montan wax is bleached with a regenerated CrO_3 soln. contg. Cr compds. (calcd. as Cr_2O_3) 70–140, free H_2SO_4 200–440 and total H_2SO_4 250–550 g. per l. Cf. *C. A.* **25**, 800.

Olefins. I. G. FARBENIND. A.-G. Fr. 36,812, Mar. 12, 1929. Addn. to 643,413. A gas rich in olefins is obtained by introducing coal into the median zone of a furnace heated to an appropriate temp. and allowing the gaseous products to escape at the top of the furnace, while the coal in its descent is freed from all volatile constituents.

Plant for treating adsorption oil containing benzene and dilute aqueous ammonia. G. V. KOPELEVICH. Russ. 47,970, May 25, 1929. Constructional details.

Gas. HUMPHREYS & GLASGOW, LTD. Fr. 690,533, Feb. 25, 1930. A gas suitable for domestic or industrial use is made by passing blue water gas over an appropriately

heated catalyst to transform an appreciable part of the H and CO in the gas into CH_4, CO_2 and steam, passing more water gas with steam over a heated catalyst to transform an appreciable part of its CO into H and CO_2, adding the second gaseous product to the first and sepg. CO_2 and steam.

Purification of gas. Soc. Belge d'electro-synthèse "Sobelsyn" (Soc. anon.). Fr. 689,440, Feb. 5, 1930. Ammoniacal waters from the distn. of coal, etc., are treated with $FeSO_4$, filtered and used for removing NH_3 and S from distn. gases. The wash waters may be electrolyzed in the anodic compartment of an electrolytic bath, the diaphragm of which is composed of a layer of crude natural phosphate deposited on the cathode for the production of a *fertilizer*.

Removing sulfur compounds from gases. I. G. Farbenind. A.-G. Brit. 334,526, March 2, 1929. S-bearing gases such as coal gas, coke-oven gas or producer gas are purified, with recovery of sulfate and S, by at least partially converting the H_2S into SO_2 by catalytic oxidation, and bringing the hot gases produced into contact with a liquid contg. thiosulfates, decompg. them with formation of sulfates and S. Various details and modifications of procedure are described. Cf. *C. A.* **25**, 400.

Combustible gas. Humphreys & Glasgow, Ltd. Fr. 689,969, Feb. 14, 1930. A light combustible gas is made by the following operations: air is blown through an ignited mass of fuel thereby producing gases, Fe_2O_3 is reduced and metallic Fe is heated by contact with these gases, H is produced by passing steam in contact with the Fe which becomes oxidized, water gas is produced by injecting steam through the fuel and the H is mixed with the water gas. An app. is described.

Combustible gas. Humphreys & Glasgow, Ltd. Fr. 690,356, Feb. 21, 1930. A gas suitable for domestic or industrial purposes is made by removing part of the CO from water gas and transforming the rest of the CO and the whole or part of the H into CH_4, using the removed part of the CO for the production of H and adding the H thus produced to the gas contg. CH_4. Or part of the CO is removed from coal gas and used for the production of H which is added to the coal gas or to water gas contg. CH_4.

Synthetic products from industrial gases. I. G. Farbenind. A.-G. Fr. 690,091, Feb. 17, 1930. In the manuf. of synthetic products such as alcs., aldehydes, acids or NH_3 from industrial gases contg. CO, excess CO in the gas not required for the synthesis is removed by using it for the prepn. of Fe carbonyl.

Operating industrial gas burners. Askania-Werke A.-G. vorm. Centralwerkstatt Dessau und Carl Bamberg-Friedenau. Ger. 510,207, Aug. 6, 1927. The air and the gas supplied to large gas burners for Cowper app., etc., are given, before they are mixed, a velocity substantially above the ignition velocity of the mixt.

Coal-gas purification. Gas Light & Coke Co., H. Hollings, S. Pexton and W. K. Hutchison. Brit. 334,619, June 11, 1929. NH_3 is recovered from gas by scrubbing it with weak ammoniacal liquor previously formed by cooling the gas and contg addnl. CO_2. An arrangement of app. and various details and modifications of procedure are described.

Dry purifier for coal gas, etc. Thyssen'sche Gas- und Wasserwerke G. m. b. H. and Andreas Borchardt. Ger. 510,127, Dec. 8, 1928.

The utilization of spent lyes from the purification of liquid hydrocarbons extracted from coal gas. Heinrich Schmidt. Ger. 510,487, Nov. 25, 1928. The NaOH lyes are uniformly mixed with the water used to wash out NH_3 from the gas, the mixing being effected when the water has dissolved a certain amt. of NH_3.

Washing flue gases. London Power Co., Ltd., and S. L. Pearce. Brit. 334,660, July 16, 1929. Various details of app. are described, comprising atomizers, baffle-board scrubbers and towers. After washing with an alk. liquor, the gas may be passed through a moisture eliminator, and in one of the treating chambers the gas may be brought into contact with a ferruginous or other suitable catalyst for oxidizing the SO_2 fumes present. Ozone or hot air may be supplied to the gas at the base of a chimney.

Device for purifying flue gases. August Hildenbrand. Ger. 510,602, April 7, 1929.

Apparatus for treating furnace or residual gases. London Power Co., Ltd., and Standen L. Pearce. Fr. 689,269, Feb. 3, 1930.

Water gas. Dampfkesselfabrik vorm. Arthur Rodberg A.-G. Fr. 690,126, Feb. 17, 1930. Means is described for recovering the heat lost in the manuf. of water gas

Water gas. N.-V. Silica en Owenbouw Mij. Fr. 689,854, Feb. 13, 1930. Water gas is made simultaneously with the cooling of incandescent coke by passing steam or water through the coke and leading the resulting mixt. to a chamber contg. a reducing agent such as small coke kept at a temp. sufficient to reduce CO_2 to CO.

Carbureted water-gas apparatus. Wm. J. McClurg. U. S. 1,788,400, Jan. 13. Various details of construction are described.

Oil and water gas. Humphreys & Glasgow, Ltd. Fr. 690,302, Feb. 20, 1930. A combustible mixt. of oil gas and water gas is made by blowing air into an ignited mass of fuel in a generator and causing the combustion of the gaseous products of this blowing in a heat-storing receiver communicating with the generator. A fluid hydrocarbon is at the same time introduced into the generator and a further quantity of fluid hydrocarbon into the receiver. The hydrocarbon is caused to pass in 2 currents, one through the generator and the mass of fuel where C is deposited, and the other through the receiver. The resulting oil gases are evacuated from the generator and the receiver and steam is injected into the mass of fuel to insure combustion of the excess C deposited therein and form water gas which may be carbureted with a hydrocarbon in the receiver and mixed with the oil gases.

Mixed oil gas and water gas. H. G. Terzian (to Humphreys & Glasgow, Ltd.). Brit. 334,485, July 11, 1929. Various details of app. and procedure are described of a process of the type in which oil gas is passed through an ignited fuel bed and the C deposited from this step is used in water-gas production. Cf. *C. A.* **25**, 194.

Oil-gas generator. F. J. West, E. West and West's Gas Improvement Co., Ltd. Brit. 334,346, Aug. 1, 1929.

Gas producer. Humphreys & Glasgow, Ltd. Fr. 690,089, Feb. 17, 1930.

Gas producers. I. G. Farbenind. A.-G. Fr. 36,660, Mar. 27, 1929. Addn. to 631,948. The gasifying agents are heated in the shaft of the producer above the charge of coal by the heat from the gases produced.

Gas producers. I. G. Farbenind. A.-G. Fr. 36,817, Mar. 27, 1929. Addn. to 631,948. Means for introducing the gasifying agents is given.

Gas producers. I. G. Farbenind. A.-G. Fr. 36,858, May 2, 1929. Addn. to 669,789 (*C. A.* **24**, 1962).

Gas generator for moist fuel. Jules U. Marguet. Ger. 510,601, June 28, 1929. An app. is described for the distn. of wood, etc., in which provision is made for condensing and removing the water.

Automatic valve for gas lines. David L. Brown (two-fifths to George Acuff). U. S. 1,788,368, Jan. 13. Various structural details are described of a valve which shuts off flow in pipe lines in case of breakage.

Electrically-controlled pressure-regulating system suitable for gas-supply systems. Jacob C. Groble (to Groble Gas Regulating Co.). U. S. 1,788,429, Jan. 13. Structural features.

Separating gaseous mixtures by liquefaction. Soc. l'air liquide (Soc. anon. pour l'étude et l'exploitation des procédés Georges Claude). Ger. 510,418, June 12, 1925. In the manuf. of H by partial liquefaction of coke-oven gases, etc., the removal of CO and CH_4 is completed by expanding the H, then introducing liquid N and allowing it to evap., and circulating the cold gas around the tubes in which the final condensation is effected under pressure. The method may be applied to other gas mixts., a suitable liquefied gas being substituted for the N. Cf. *C. A.* **24**, 902, 5469.

Treating tar. V. E. Rakovskii and A. A. Vinogradov. Russ. 25,150, July 5, 1928. Tars obtained from low-temp. and high-temp. carbonization of peat, brown coal, etc., are steam-distd. to remove light fractions. The residue is dissolved in gasoline and the bottoms left over are treated with a 10–40% H_2SO_4. The method is characterized by cooling the gasoline soln. to 8–10° to sep. the crystallizable components. The remaining soln. is treated with a strong alkali, and fractionated with steam or under a vacuum. The paraffin is then sepd. from the higher-boiling fractions by cooling and crystn.

Fractionating tars, oils, etc. Eugen Kárpáti. Fr. 691,360, Dec. 31, 1929. Tars, tar oils, mineral oils, etc., are sepd. into industrially utilizable fractions by dissolving the crude material in aq. solvents such as 55% alc. with pressure obtained by heating. The various fractions are afterward sepd. from the soln. by a gradual lowering of the solvent power of the solvent, in the order of their increasing soly. If the crude material is difficultly sol. the last fraction need not be dissolved and is thus sepd.

Tar distillation. The Barrett Co. Fr. 688,837, Jan. 25, 1930. Tar is heated in a continuous manner in an exteriorly heated distn. app. at a temp. above the b. p. of part of the oily constituents and then brought in direct contact with hot gases from the carbonization or gasification of coal. Fr. 688,838 describes an app. in which the tar is heated in an exteriorly heated distn. app. to a temp. sufficient to ext. by distn. a part of the oils. The vapors of constituents of low b. p. which are difficult to condense when mixed with gases are extd. and condensed separately and the residues are submitted to a

fresh distn. by direct contact with hot gases from the carbonization or gasification of coal.

Distilling tars. COMPAGNIE TECHNIQUE DES PÉTROLES. Fr. 689,294, Dec. 10, 1929. Tars from lignite, coal or bituminous schists are decomposed by non-destructive distn. into 2 fractions, one of which contains pressable paraffin and the other unpressable paraffin, these fractions being freed separately from paraffin.

Coal-tar products. FRANK COOKE. Ger. 510,940, Dec. 25, 1928. Plant is described for the direct production in a coke furnace of road-surface tar and by-products. Crude tar is condensed from the coke-furnace gases in air-cooled tubes and led to a container maintained at 160–190°. Part of the tar is used to trickle over the plant to maintain the temp. and the remainder is washed with steam. The resulting vapor is passed into an NH_3-satd. washer and the tar led to a steam distn. app. after which it is thickened by heating. The light hydrocarbons are sepd. from the vapor and the cresote oil is led back to the tar.

Plastic pitch or artificial bitumen from tar, etc. C. F. BROADHEAD and R. S. ANDREWS. Brit. 334,380, Nov. 29, 1928. Tar is heated with a small proportion of an aldehyde such as formaldehyde, acetaldehyde or furfuraldehyde (about 1–4%) and a catalyst such as NH_3, $(NH_4)_2SO_4$, H_2SO_4 or HCl (suitably at 80–95° for 8–16 hrs.) and subsequently air or other oxidizing gas is passed through or over the material until it has hardened (suitably at 100–200° for 10–30 hrs.). Before this latter treatment, a second catalyst may be added, such as Fe sulfate or Cu sulfate.

Coke. ALFRED POTT. Fr. 689,278, April 26, 1929. A valuable coke in small pieces is made by drying and heating coal in an app. to a temp. which is near, and if possible directly below, the decompn. temp. of the coal, the product thus obtained being afterward introduced into another app. in which it is submitted to a partial carbonization the 2nd app. being exteriorly heated and brought to a sufficiently high temp. before introducing the material.

Coke ovens having vertical chambers. EVENCE COPPÉE & Co. Fr. 36,650, Mar 1, 1929. Addn. to 616,460.

Regenerating coking oven. WILHELM MÜLLER. Ger. 512,219, Oct. 7, 1928 Addn. to 489,840 (*C. A.* **24**, 2279).

Method and plant for discharging coke-oven retorts. INTERNATIONAL HOLDING DE DISTILLATION ET COKEFACTION À BASSE TEMPERATURE ET MINIÈRE (HOLCOBAMI) SOC. ANON. Ger. 510,126, Feb. 19, 1930.

Combined coke-cooler and water-gas producer. C. OTTO & Co. G. M. B. H. Ger. 510,328, Feb. 15, 1929.

Cooling glowing coke. C. OTTO & Co. G. M. B. H. Ger. 510,915, April 17, 1927. An app. is described in which glowing coke is discharged down a chute against a countercurrent of cooling water or steam, with simultaneous production of superheated steam.

Coking or carbonizing. I. G. FARBENIND. A.-G. (Heinz Thienemann, inventor Ger. 510,065, Jan. 14, 1925. Initial materials for use in continuous coking processes are prevented from caking during the process by preliminary compression. The method is particularly applicable to the manuf. of active C in rotary retorts.

Coking lignite. FRITZ SEIDENSCHNUR. Ger. 512,387, Aug. 14, 1925. Dried or briquetted lignite is treated with hot gases in a countercurrent app. under such conditions that the lignite is heated as rapidly as possible to a temp. approaching 400°. The method results in the production of *light oils*, as well as *tar rich in bitumen*, and a good *burning coke*.

Coking lignite. KARL NOWAK. Ger. 510,573, Jan. 12, 1926. Addn to 488,500 (*C. A.* **24**, 2586). The method of Ger. 488,500 is modified by using a bituminous binder, *e. g.*, coal-tar pitch, for the lignite briquets.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

The constituents of petroleum distillates. II. Determination of the aniline point of low-boiling paraffin-naphthene mixtures. A. SCHAARSCHMIDT, H. HOFMEIER AND HANS LEIST. *Z. angew. Chem.* **43**, 954–7(1930).—The *naphthene content* of a mixt. of paraffin and naphthene hydrocarbons can be calcd. from the formula: $N = (A - A_m)/(A - a)$, in which A is the *aniline point* of the component having the higher aniline point,

A_m is the aniline point of the mixt., and a is the aniline point of the other component. The method is more reliable with higher-boiling than with lower-boiling compds. To what extent the errors can be eliminated by detg. the aniline point in a sealed tube is now being investigated. The naphthene content of ternary and quaternary mixts. of naphthenes and paraffins can also be calcd. by combining the hydrocarbons of each class and detg. the aniline points of those combinations before detg. the aniline point of the whole. The method is reliable only for detecting changes in known mixts. It can give only approx. results for unknown mixts. because of the great variation in the aniline points of the naphthenes. EMMA E. CRANDAL

Investigating Sakhalin crude oil. S. S. NAMETKIN AND S. S. NIFONTOVA. *Neftyanoe Khozyaistvo* **19**, 421-2(1930) —A sample of crude oil from the river Chakrui had a sp. gr. of 0.943. E_{50} of 4.38, Pensky-Martens flash 98°, cold test —15°, and excise resins 28%. An Engler distn. yielded 4% below 250°, 13.5% up to 275°, 29% up to 300°, residue 68.0% and loss 3%. This is an asphalt-base crude oil, without any gasoline fraction and with a very small amt. of kerosene. A vacuum distn. of the residue yielded about 20% of lubricating-oil distillate of —5° cold test. The crude oil from Lyangri had a sp. gr of 0.951, E_{50} of 3.6, P.-M. flash 104°, cold test —19° and excise resins 19%. An Engler distn. produced 1% below 250°, 12.5% below 275°, 27.5% below 300°, 70.0% residue and 2.5% loss. A vacuum distn. of the residue yielded about 18% of a lubricating-oil distillate of +3.5° cold test, with a probably small content of paraffin. Both crude oils were weathered, and the samples supplied were insufficient to make a complete investigation. A. A. BOEHTLINGK

The true value of the Alberta asphaltic crude oils. C. C. COULTER. *Petroleum Times* **24**, 3-5(1930).—The Wainwright, Ribstone and Skiff oil fields in Alberta, Canada, yield a crude oil having a lubricating-oil content of about 50%. The anticline extending for 200 mi. in a general north and south direction in eastern Alberta will probably be found to contain important deposits of crude oil, sufficient to reduce materially Canada's dependence upon the United States for many petroleum products. E. E. C.

Distillation of heavy bottom oils by the Pengu-Gurvich-Nersesov method. G. TER-GRIGORYAN. *Azerbaidzhanskoe Neftyanoe Khozyaistvo* **1930**, No. 11, 74–82.—Heavy bottom oils obtained in the distn. of petroleum were passed through an asphalt heat exchanger, leaving it at 180-200°, and were pumped through a pipe still and heated to 400-410°. They were then flashed together with steam admitted through nozzles in the lower part of the evaporator and passed through a layer of Raschig rings through the upper part of the evaporator subdivided into seven chambers, each of which delivered a certain cut. Thirty-two to thirty-five % of the bottom oils was condensed in this column; the vapors and steam were passed through a large vapor line on the top of the column into the top of a second column where an addnl. 5-6% was condensed, together with steam. Permanent gases were removed and an abs. pressure of the order of 100 mm. was maintained in the unit by a vacuum pump connected to the upper part of a barometric condenser, the latter being connected to the second column. From 4 to 7% of oil was recovered in the barometric condenser. The semiasphalt pptd. on the bottom of the evapg. drum was passed through the heat exchanger for preheating the feed and was then worked up for asphalt. Cooling coils placed in the drums were cooled by steam H_2O which was recirculated after being chilled in water coolers. The Nersesov-type pipe still used in the above unit had two combustion chambers and two chambers in which the oil-heating pipes were placed. It also had two chambers for superheating steam. The oil-heating pipes were arranged in two banks in each chamber. The two upper banks were located near the roof of the combustion chamber, which was 2 m. high. They were heated by radiant heat, while the two lower banks were placed between the roofs where they were heated by convection and radiation. The hot combustion gases then passed into the superheater chamber which had also a sep. furnace to superheat the steam (if necessary) to higher temps. than could be obtained by the heat from the oil-heating furnace. The unit had a throughput of 50-75 metric tons of charging stock, and it is claimed that there was practically no decompn. The furnace had an efficiency factor of 0.58. Oils produced in this unit are similar to the American bright stocks except for their higher cold test. A detailed description of the parts of the equipment, a layout of the plant and analyses of intermediate and final products are furnished. A. A. BOEHTLINGK

An examination of shales associated with oil-bearing strata in the United States. E. MCKENZIE TAYLOR. *J. Inst. Petroleum Tech.* **16**, 681-3(1930).—In samples of 19 oil-bearing shales from the U. S., replaceable Na and Ca, and p_H value were detd. All the clays were alk. and in all of them the replaceable Na greatly exceeded the replaceable Ca. This is the condition which would be found if the clays had undergone base exchange with solns. of Na salts and the Na clays had subsequently been hydrolyzed by

contact with fresh water. This has been the invariable inference from all the previous examns. of oil shale. The 19 samples covered the geological range from Ordovician to upper Miocene. EMMA E. CRANDAL

Hydrogenation adapted to the oil refinery. M. W. BOYER. *Chem. Met. Eng.* **37**, 741–5(1930); cf. *C. A.* **24**, 5987.—B. describes the pilot hydrogenation plant at the Standard Oil of Louisiana refinery (Baton Rouge), and gives data on typical hydrogenated distillates. T. H. CHILTON

Industrial uses of fuel oil. I. LUBBOCK. *Petroleum Times* **24**, 671–3, 719–20 (1930).—Oil has peculiar advantages as a fuel for heating glass tanks, china, pottery and brick kilns, and enameling muffles, for drying bricks and tea, for bread, biscuit and cake baking, for tube-welding furnaces, for smelting tin ore, in reverberatory furnaces, and for other ore- and metal-treating operations. Pure Ni castings weighing 860 lb. each, free from porosity, were made by oil heat. This metal required a pouring pt. of 1600°. Losses of Sn, Al, brass, bronzes and gun metals in the combustion gases are low. EMMA E. CRANDAL

Breaking emulsions. N. BALUKHOVSKII. *Neftyanoe Khozyaistvo* **19**, 460–1 (1930).—Heavy Voznesenskii crude oil of 0.900 and higher sp. gr. was dehydrated by passing it through a Cornwall steam boiler in which it was heated to about 100°. The crude oil was continuously passed through this boiler into a settling tank from which it overflowed into a storage tank. The oil so obtained contained less than 0.25% of water. A. A. BOEHTLINGK

Safety in oil-cracking operations. E. M. MATSON. *Petroleum Times* **24**, 755–7, 779–80, 839–40(1930). EMMA E. CRANDAL

Cross cracking units. A. MARGULOV. *Azerbaidzhanskoe Neftyanoe Khozyaistvo* **1930**, No. 11, 107–19.—A Cross unit installed in the Ponca City refinery of the Continental Oil Company was charged with a mixt. consisting of 35–40% of a gas oil of 0.850 sp. gr. and 65–60% of condensate, the capacity of this unit being 2500 bbls. The following yields were obtained: gasoline 27, condensate 57, heavy residue 10 and gas and loss 6%. A detailed description is given of Cross units installed in the Champlin Refinery Co.'s plant in Enid, Okla., the Continental Oil Co. refinery in Ponca City, Okla., and the Barnsdall Oil Co. refinery in Okmulgee, Okla., including layouts, flow sheets, temps., construction details, etc. A. A. BOEHTLINGK

Cracking of Rangoon paraffin in vapor phase. J. W. HEYMANS. *J. Inst. Petroleum Tech.* **16**, 661–77(1930).—Rangoon paraffin in liquid form was introduced at const. rate into an Fe tube filled with glass tubing and heated in an elec. furnace. All products of cracking except the uncondensable gases were collected and analyzed. Time in the reaction tube was calcd. The pressures maintained in the 5 expts. were: 10 (max.), 10 (max.), 10, 30 and 30 mm.; temps., 450°, 600°, 600°, 700° and 700°; cracking periods, 1.7, 1.4, 1.2, 3.8 and 1.54 sec. More cracking occurs at 450° in vapor than in liquid phase as the consequence of the greater activity of the gas mols. and more contact with the tubing and the hot walls. H_2 splits off even at 360°. After cracking at the end of the hydrocarbon chain, cracking proceeds from point to point along the chain, breaking up the mol. by degrees. At 700°, nearly all the nongaseous products of cracking were unsatd. compds. EMMA E. CRANDAL

Removing naphthenic acids. YU. EMMUIL. *Azerbaidzhanskoe Neftyanoe Khozyaistvo* **1930**, No. 11, 90–5.—An app. constructed by E. exts. 85–90% of the naphthenic acids from the oil. It consists of a vertical cylinder, the middle section of which has a steam coil to heat the gas oil and other distillates to 70–75°. The oil enters at the bottom through a perforated pipe and leaves through the top. The caustic soln. is passed from the top countercurrent to the oil and is discharged through the bottom together with the soap. A high efficiency is claimed as well as low consumption of steam and caustic. The naphthenic acid contents of various cuts of Baku petroleum and statistical data are also given. A. A. BOEHTLINGK

Adsorption power of Grozny clays. V. BARANOV. *Neftyanoe Khozyaistvo* **19**, 446–59(1930).—Over 200 samples of Russian and some American clays were used in the expts. Some Russian clays had a higher adsorbing power (under identical conditions) than known American and German brands, both before and after activation. A. A. BOEHTLINGK

The influence of engine conditions on the antiknock rating of motor fuels. R. STANSFIELD AND F. B. THOLE. *Engineering* **130**, 468–70, 512–4(1930); cf. *C. A.* **23**, 2813.—The method of conducting tests is described in detail, with a method for calibrating an engine in the audibility test. The speed used is 750 r. p. m.; fuels likely to pre-ignite can be detected by increasing the speed to 1200. Different engines checked antiknock ratings by using a 12° spark advance, which is slightly overadvanced for max

power. Some abnormal spirits will yield inconsistent results unless a finished inlet system is used, though most fuels cause no trouble if preheated to 120°F. From the results of 24 different engines, it was found that a general comparison is obtained if the rise in the highest useful compression ratio (H. U. C. R.) from a standard reference fuel to that under test is given. A change from cast-Fe to Al pistons caused a rise in the H. U. C. R. by 0.3 for the reference standard fuel (a straight-run spirit). When engines are calibrated in terms of the change in ratio for a given pinking intensity from the pro-knock standard up to the max. C_6H_6 blend which may be used, the results agree within 2%, irrespective of engine or operator. The bouncing pin is suitable only for small cylinders if the design is such that there is no risk of pre-ignition with heavy continuous pinking. The time lag with the bouncing pin is decreased by having a not too clean or too dirty engine. For fuels showing a time lag, duplicate tests should be made. The change of rating of C_7H_{16} blends with rise in the jacket temp. decreases as the amt. of C_7H_{16} decreases. For a blend 73% of C_6H_6 and 27% of C_7H_{16}, there is no detectable difference at 120° and 350°F. Results with ethyl fluid check Bartholomew's detns. There is no evidence that C_6H_6 loses its effect at high temp. For the 73/27 C_6H_6-C_7H_{16} mixt., no change was detected on varying the inlet air temp. from 60° to 120° and 180°F. The throttling effect causes an increasing deviation between the bouncing-pin and the audibility methods as the antiknock value of the sample rises. An alteration of plug-point gap and plug reach causes a very small change and was detected for one fuel only. The humidity is unimportant at 65°F. if H_2O is present as vapor. Above this temp. a correction must be applied. ARTHUR FLEISCHER

Dry distillation of tolu balsam. JUSTIN DUPONT AND JEAN-JACQUES GUERLAIN. *Compt. rend.* **191**, 716–7(1930) —Dry distn. of tolu balsam gives appreciable quantities of monomethyl ethers of pyrocatechol and of its homologs, identical with those that Behal and Choay extd. from the creosote of wood pitch. ALICE W. EPPERSON

Colorimetric method for determining turpentine oil in the atmosphere (KORENMAN) 7. A new buret for the determination of unsaturated and aromatic hydrocarbon oils (FORMÁNEK) 1. Sampling apparatus for petroleum products. P. I. VYAKHIREV. Russ. 33,094, Sept. 25, 1928. Constructional details.

"Sweetening" sour petroleum oil. HUGH H. CANNON and WRIGHT W. GARY (to Cannon-Prutzman Treating Processes, Ltd.). U. S. 1,789,167, Jan. 13. "Sour" oil is treated with an incoherent comminuted solid reagent comprising $Ca(OH)_2$, PbO and S, "sweetened" oil is sepd. from the reagent, and further quantities of "sour" oil are treated with the sepd. reagent and with addnl. S. U. S. 1,789,168 describes a process for "sweetening" sulfurous petroleum oils by converting mercaptans into Pb mercaptides by treatment with a powd. solid reagent contg. PbO and a hydroxide of an alk. earth metal.

Separating constituents of petroleum-water emulsions. FRANZ R. MOSER (to N.-V. de Bataafsche Petroleum Maatschappij). U. S. 1,788,684, Jan. 13. The emulsion is treated with a colloidal material obtained by treating mineral lubricating oil, substantially free from substances likely to resinify, with an excess of strong H_2SO_4, dilg. the sludge with water and sepg. unaltered oil from the aq. liquid contg. the colloidal matter.

Separating petroleum soaps. E. V. STOCK. Russ. 46,666, May 8, 1929. Alkali sludge is first acidified so as to sep. a very small quantity of free naphthenic acids and then is salted out.

Apparatus for heating petroleum oils before distillation. ÉTIENNE J. F. ROUSSEL. Fr. 689,004, Jan. 28, 1930.

Apparatus for distilling petroleum. BETHLEHEM STEEL CO. Fr. 690,266, Jan. 29, 1930.

Pipe still suitable for use in distillation of petroleum oils. GEORGE W. WATTS (to Standard Oil Co. of Ind.). U. S. 1,789,267, Jan. 13.

Fractionating tower suitable for distillation of petroleum oils. THOMAS DEC. TIFFT and WM. MENDIUS (to Sinclair Refining Co.). U. S. 1,789,059, Jan. 13.

Oil-distillation apparatus. RICHARD F. GILDEHAUS, JR. U. S. 1,788,947, Jan. 13. A continuous closed distn. app. for hydrocarbon oils comprises 2 stills, with an outlet for the first still running from a point substantially above its bottom, and a pump adapted to circulate oil in the other still, a pipe being connected with the outlet of the first still so as to permit oil to flow by gravity to an intake for the pump, and a U-bend being provided in the pipe to compensate for pressure differences in the stills. Various details of the installation are described.

Distilling hydrocarbon oils. GENTRY CASH (to Standard Oil Co. of Ind.). U. S. 1,788,982, Jan. 13. Oil is passed in a confined stream through a heating zone such as a pipe coil and thence discharged into an enlarged chamber in which sepn. of vaporized products takes place. Unvaporized oil is removed from this chamber and forced under applied mech. pressure such as that of a pump into a stripping zone where it is subjected to direct contact with steam to remove lighter constituents, and the steam and assocd. vapors are forced into the stream of heated oil at an intermediate point in the heating zone. App. is described. Cf. *C. A.* **25**, 412.

Distilling hydrocarbon oils. PHILIP L. KRAUEL (to Standard Oil Co. of Ind.). U. S. 1,789,004, Jan. 13. A process and app. are described generally similar to those of U. S. 1,788,982 (preceding abstract) except that inert gas such as steam is injected into the unvaporized oil and serves to force it to the stripping zone.

Fractionating hydrocarbon oils. IRA B. FUNK. U. S. 1,789,173, Jan. 13. A mixt. of light and heavy hydrocarbons such as absorption oil and natural gas gasoline is vaporized and mixed with steam, and the mixt. is fractionated to eliminate undesired heavy hydrocarbons; the light desired hydrocarbons are condensed in 2 stages, and a portion of the condensed desired light hydrocarbons is continuously cycled through the vaporous light desired hydrocarbons in the first condensing stage, and condensed steam is sepd. and withdrawn from the reflux liquid in the first condensing stage. An arrangement of app. is described.

Hydrocarbons. I. G. FARBENIND. A.-G. Fr. 37,096, May 2, 1929. Addn. to 643,413 (*C. A.* **23**, 1415). Gaseous olefins, benzines and aromatic hydrocarbons are made by soaking porous material such as pumice stone, slags or coke with tars, mineral oils, residues from the distn. of oils or residues from the hydrogenation under pressure of coal, tars, mineral oils, etc., and passing the soaked material through a chamber heated to a high temp.

Liquid hydrocarbons. I. G. FARBENIND. A.-G. Fr. 691,244, Mar. 6, 1930. Valuable liquid hydrocabons are obtained by submitting the residues from the condensation or refining of hydrocarbons such as mineral oils, tar oils or oils obtained by hydrogenation under pressure, to a hydrogenation under pressure in the absence of catalysts, or in the presence of catalysts not sensitive to S. Examples are given.

Refining hydrocarbons. COMPAGNIE DES MINES DE VICOIGNE, NOEUX & DECOURT. Fr. 691,118, May 8, 1929. Oils obtained by the distn. at high or low temps. of schists, lignites, etc., and petroleum oils (specially those obtained by cracking) are desulfurized and refined by heating them with or without pressure with metallic halides, particularly $TiCl_4$, which transform the unsatd. hydrocarbons and the stable S compds. into satd. hydrocarbons and unstable S compds. easily eliminated by Na plumbite.

Nozzle for injecting hydrocarbons into fused metals or salts, for distillation or cracking. PREUSSISCHE GEWERKSCHAFT RAPHAEL. Ger. 512,427, May 27, 1928.

Cracking hydrocarbons. N. V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 334,241, May 30, 1929. C_4H_{10} and other hydrocarbons are cracked by passing them through molten baths of non-metallic substances such as a fused mixt. of equimol. proportions of $CaCl_2$ and $BaCl_2$, m. about 500°. Butane thus treated at 750° yields a mixt. contg. about 18% each of C_3H_6 and C_2H_4. Various other chlorides may be used for the molten baths, and molten Te also may be employed, serving as a catalyst. An app. with an Al lining may be used.

Cracking hydrocarbon oils. EUGENE C. HERTHEL (to Sinclair Refining Co.). U. S. 1,789,072, Jan. 13. Vapors from pressure cracking are passed through a reflux condenser, at an intermediate point of which they are brought into direct contact with raw oil to be supplied for the pressure distn. There is also introduced into the reflux condenser in direct contact with the vapors passing through it, at a plurality of points spaced further along the path of vapor travel, a light oil that is vaporized substantially completely under the conditions prevailing in the reflux condenser. The oil mixt. including condensate and unvaporized raw oil is returned from the reflux condenser to the pressure distn., so that entrainment in the reflux condensate of light constituents

suitable as components of the desired distillate is reduced. The app. is described. Cf. *C. A.* **25**, 199,808.

Cracking hydrocarbon oils. FRANK C. VANDE WATER (to Petroleum Laboratories, Inc.). U. S. 1,788,933, Jan. 13. A body of oil is subjected to a vaporizing temp., the moving vapors are subjected to a superheating temp. in a restricted elongated space such as a pipe coil and the vapors are then permitted to expand to reduce their velocity while subjected to substantially the same temp. (the entire operation taking place under substantially atm. pressure) An app. is described.

Cracking process. N. V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Fr. 689,551, Feb. 7, 1930. Petroleum oils contg. heavy substances easily coked are cracked by a combination of a cracking process of short period with a cracking process of long period. In this combination the treated oil is first submitted to a short primary cracking and afterward joined with the flow from the long secondary cracking, the heavy easily cokable material being afterward eliminated from the reunited current. The distillate and the gases formed in the 2 cracking phases, being sepd. from the heavy vapors remaining untransformed, are returned to reflux and passed in the secondary process of the long period. An app. is described.

Fractional extraction of mineral oils with nitrobenzene. SEYMOUR W. FERRIS (to Atlantic Refining Co.). U. S. 1,788,569, Jan. 13. A viscous oil contg. paraffinic and naphthenic hydrocarbons is sepd into fractions, relatively more concd. in these different kinds of hydrocarbons, by extg. the oil with $PhNO_2$ which has a greater solvent action on the naphthenic hydrocarbons.

Refining mineral oils. DEUTSCHE GASOLIN A.-G. Fr. 690,068, Feb. 15, 1930. Oil is removed from kaolin which has been used for refining mineral oil, by heating the kaolin with a dild. mineral acid in a closed vessel to a temp. above the b. p. of the dild. acid. The kaolin may first be treated with org. solvents.

Purifying crude mineral oil. KIDD W. HICKEY. U. S. 1,789,233, Jan. 13. A soln. of $NaHCO_3$ and borax is added to the oil, and, separately and simultaneously, HCl is added to produce a violent reaction and effect sepn. of water and assocd. impurities.

Oil for heating. IDELEANU G. M. B. H. Ger. 512,020, Oct. 8, 1927. A heating oil comprises the cracking residues of heavy hydrocarbons, to which the ext obtained from mineral oils by means of liquid SO_2 is added, in order to prevent sepn. of asphaltic and like constituents.

Purifying oils, etc. I. G. FARBENIND. A.-G. Fr. 689,625, Feb. 8, 1930. Finely dispersed impurities of a colloidal nature are sepd. from oils or other liquids by filtration through the finely divided residues contg. coal obtained in the hydrogenation, extn. or cracking of coal, tars, mineral oils, etc.

Gas and liquid separator suitable for use at oil wells. LEO C. DUGGAN. U. S. 1,788,990, Jan. 13. Structural features.

Removing naphthenic acids and their salts from bore-hole waters. S. I. RYABCHENKO. Russ. 54,532, Sept. 12, 1929. The waters are purified by consecutive treatments with H_2SO_4 to destroy naphthenic acids, settling out of naphthenic acids and adsorption of the last acid particles by adsorbents.

Recovering sulfonic acids from cracked residues. M. A. BESTUZHEV and A. N. SAKHANOV. Russ. 29,699, July 3, 1928. Residues obtained in cracking heavy oil are treated with strong H_2SO_4, which should not contain free SO_3, and the sulfonic acids are then extd. from the products of reaction by the usual methods.

Precipitating acid sludge. I. B. BARSAMOV. Russ. 64,820, Feb. 20, 1930. Acid sludge obtained after treatment of heavy lubricating oils with H_2SO_4 is pptd by a treatment with a soln. of caustic obtained after the first neutralization of acid-treated oil. This soln. is, as a rule, 3.5° to 4° Bé., and for the above treatment it should be brought up to 5° Bé.; it also must be freed of floating org. substances.

Sulfonic acids. SUDFELDT & Co. (Milan Gelbke, inventor). Ger. 510,303, Aug. 30, 1923. The acid tars obtained in purifying mineral oils or lignite- or shale-tar oils are treated with alkali, purified (if desired) by distn. *in vacuo* with superheated steam and then treated with a soln. of alkali in an org. solvent, *e. g.*, MeOH or EtOH. The unsulfonated constituents sep., and the clarified soln. is evapd. and acidified. The sulfonic acids so obtained have strong fat- and oil-splitting properties.

Apparatus for a continuous treatment of gasoline and kerosene. I. G. TZURIKOV. Russ. 15,565, Jan. 3, 1927. A treating vessel has a number of vertical mixing chambers and settling chambers arranged above the treating chambers. They are combined into a continuous chain in which parts having identical shapes are placed in terraces. The reagent is mixed with the petroleum product in a vessel which has a perforated inverted

cone supported in its upper part by edges tightened between flanges and which connects with the lower part of the mixing chamber.

Motor fuel. FRANÇOIS M. C. A. LECLÈRE. Fr. 691,348, May 23, 1929. An improved fuel contains, *e. g.*, gasoline 73–74, benzene 25 and an oxygenated combustible such as alc. 1–2% by vol.

Motor fuels. I. G. FARBENIND. A.-G. Fr. 691,101, Mar. 5, 1930. Agents added to fuels to raise their *antiknock properties* are made of a mixt. of Fe carbonyl and aromatic amines or their *N*-alkyl or *N*-aryl derivs. or primary or secondary aliphatic amines contg. up to 3 C atoms in the side chain. Other substances such as alcs., lubricants or dyes may also be added.

Motor fuel. I. G. FARBENIND. A.-G. Brit. 334,181, April 27, 1929. Gasoline or the like is mixed with over 0.2 g. per gal. of Fe carbonyl (suitably about 0.1%) and with an aromatic amine contg. at least 1 alkyl radical, such as 1–15% of toluidine, methyl- or ethyl-aniline or *N*-methylxylidine. Various other substances for increasing the critical compression ratio may also be added, such as ethylene chloride, $CHCl_3$, CCl_4, PhCl, hexachlorobenzene, chloronaphthalene, the corresponding Br and I compds., NH_4 halides and their org. derivs. (as methyl NH_4 chloride), boric acid methyl or ethyl ester, silicic acid ethyl ester, Et_4Si, tricresyl phosphate, Et_4Pb, Zn oleate, Zn isovalerate, Cl propionate, Al palmitate and compds. of acetoacetic ester with Al, Mg or Fe or Cu naphthenate.

Oxidation products from crude paraffin and the like. MARTIN LUTHER and ERNST WILLFROTH (to I. G. Farbenind. A.-G.). U. S. 1,788,799, Jan. 13. Products contg. a large proportion of saponifiable substances are obtained by treating molten crude paraffin or the like with gases contg. O and nitric oxides in the presence of filler bodies such as Raschig rings and of a metal enolate such as Ba acetylacetonate or Mn acetylacetonate (suitably at temps. of 140–150°). Gases obtained by oxidation of NH_3 may be used, and use of other catalysts is mentioned such as CaO or Al_2O_3. Cf. *C. A.* **24**, 3354.

Lubricating composition. FREDERICK W. SULLIVAN, JR. (to Standard Oil Co. of Ind.) U. S. 1,789,026, Jan. 13. A product formed largely of a viscous hydrocarbon oil is given a lower "cold test" than that of the oil alone by adding the Zn or Mg compds. of acidic products derived from the oxidation of paraffin.

Lubricating oils. HENRY M. WELLS and JAMES E. SOUTHCOMBE. Fr. 689,282, July 17, 1929. About 1% of an org. acid such as oleic acid or of an alc. contg. more than 5 C atoms is added to hydrocarbon lubricating oils to increase the viscosity of the film of hydrocarbon in contact with the carrying surface. Cf. *C. A.* **24**, 2595.

Refining lubricating oil containing tarry and asphaltic substances. WALTER S. BAYLIS (to Filtrol Co. of Calif.). U. S. 1,788,653, Jan. 13. The oil is mixed with adsorbent clay and the resulting mixt. is passed in a restricted stream through a heating zone such as a pipe still where it is heated to a temp. sufficient to vaporize lighter fractions of the lubricating oil. The heated mixt. is discharged into a fractionating zone or column at a point substantially above the bottom of the latter so that the oil flows downward toward the bottom of the fractionating zone; lighter fractions are released from the mixt., the released vapors ascend toward the upper portion of the fractionating zone and are subjected to fractional condensation above the point of introduction of the heated mixt., and condensed fractions are separately removed, the mixt. of unvaporized lubricating oil and clay is withdrawn from the lower portion of the fractionating zone, and the clay is sepd. from the unvaporized oil. App. is described. U. S. 1,788,654 relates to refining crude oil of the Pennsylvania type for the production of lubricating stock, by mixing decolorizing clay with the oil and subjecting the material to treatments generally similar to those described in U. S. 1,788,653.

Purification of used lubricating oil of internal-combustion engines. LEE H. CLARK (to Sharples Specialty Co.). U. S. 1,788,911, Jan. 13. The oil is heated and water is passed in heat-exchange relation with the oil in co-directional variation by quantity with the temp. of the oil to produce steam in order to further evapn. of contaminating liquids from the oil. App. is described.

Insulating oils. SOC. ANON. DES PROCÉDÉS R. AUDUBERT (S. A. P. R. A.). Fr. 690,618, May 6, 1929. Fresh insulating oils are improved and used oils are restored by submitting them to a filtration so effective that the tensions at which a spark and an arc are established are noticeably increased and take practically the same value.

Reclaiming asphalt from asphaltic residuum oil. RUSSELL P. CROTHERS. U. S. 1,788,792, Jan. 13. Heated fuel oil is added to and fluxed with a heated mass of petroleum-residuum oil of asphaltic character; free C is permitted to settle out of the fluxed mass; the latter is withdrawn from the settled C and is reheated and cooled with settling

out of more C and high m. p. asphalt; the mass is withdrawn from the substances last settled out and is reduced to the desired consistency.

Emulsions of asphalt, fatty acids, oil, tar, etc. I. G. FARBENIND. A.-G. Brit. 334,426, Oct. 20, 1928. Emulsions prepd. with humic acid, humates or similar synthetic products prepd. by treating coal, lignite or pitchy substances with oxidizing or nitrating agents are stabilized against freezing and thawing by adding a small proportion of a volatile org. liquid such as MeOH, EtOH, acetone, formic acid or "wood vinegar."

Bituminous emulsions. ASPHALT COLD MIX, LTD. Fr. 36,752, Mar. 23, 1929. Addn. to 564,943. Stable bituminous emulsions are made by the use of soft water, pure olein and pure alkali.

Bituminous emulsions. N. V. DE BATAAFSCHE PETROLEUM-MAATSCHAPPIJ. Fr. 690,242, May 22, 1929. The stability of an emulsion of bitumen, soap and water is increased and its time for solidification reduced by adding an emulsion of asphalt, clay and water. Cf. *C. A.* **24**, 5478.

Turpentine. FREDERICK W. KRESSMAN. Fr. 689,731, Feb. 11, 1930. Turpentine contg. "resene" and abietic acid is distd. under high vacuum and at a temp. not above 260°. The distillate is sepd. into several fractions or the vapors are condensed. An app. is described.

Fatty acids. Soc. DES ÉTABLISSEMENTS BARBET. Fr. 36,953, Feb. 21, 1929. Addn. to 649,121 (*C. A.* **23**, 2722). The process of Fr. 649,121 is made applicable to forest charcoal installations. The vapors from the retort pass into a column of $CaCl_2$ which is in the form of a horizontal absorber provided with rotating vertical plates. A part of the AcOH vapor after concn. and cooling is extd. from the app., while a reflux is brought into the soln. of $CaCl_2$ to concentrate it before its entry into the absorber.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Some national aspects of the cellulose problem. FRANCESCO C. PALAZZO. *Atti III congresso naz. chim. pura applicata* **1930**, 210–25.—A review of national resources.

E. M. SYMMES

Characterization of technical celluloses by the iodine number. MAX BERGMANN AND HANS MACHEMER. *Ber.* **63B**, 2304–6(1930).—It had been shown (*C. A.* **24**, 2877) that the hydrolytic and acetolytic degradation products of cellulose reduce cold alk. I soln. The consumption of I is limited selectively to the oxidation of free CHO groups to CO_2H, and the detn. of the I no. (no. of cc. of 0.1 *N* I consumed by 1 g. of substance) affords a simple chem. method of detg. the mol. wt. of more or less homogeneous degradation products. But the I no. also affords a welcome chem. means of characterizing cellulose prepns. of non-defined chem. homogeneity, such as technical celluloses. As such prepns. are insol. in the alk oxidizing fluid, the reaction in the heterogeneous systems is complete only after several hrs. Accordingly, the following technic was adopted: The finely powd., air-dry substance, previously defatted if necessary, was ground for a short time until homogeneous with 200 cc. 0 25 *N* NaOH in a ball mill with hard porcelain balls, 50 cc. 0.1 *N* I was added, and after 4 hrs., without stopping the mill, the excess of I was titrated in the presence of 10 cc. $CHCl_3$ (to dissolve out all the I adsorbed by the cellulose) and 10 cc. of 5 *N* H_2SO_4; at the end, 10 cc. of 2% sol. starch soln. were added. Numerous expts. showed that oxidation beyond 4 hrs. did not increase the amt. of I consumed, and that, in fact, the end value is closely approached after only 1.5 hrs. Duplicate detns. checked within about ±3%. The results obtained with some 30 cellulose prepns. are reported. The I no. of unbleached cotton decreases on bleaching; evidently CHO groups are oxidized in the bleaching. Overmercerized cotton with a high content of alkali-sol. substances and very small tearing strength has no greater I no. than a good technical cellulose suitable for artificial silk; the destruction due to mercerization does not result in an accumulation of free CHO groups. On the other hand, the reducing groups of a Hoesch sulfite cellulose were markedly increased by long treatment with 5 *N* NaOH. Technical celluloses for artificial silk, with an I no. of 1.2, are easily distinguished from many celluloses used for other purposes, which have much higher I nos. Different technical artificial silks show distinct differences in their I nos. Three acetylcelluloses (1, Me_2CO-sol., Eichengrün-Miles, 52.7% AcOH; 2, low viscosity, 54% AcOH; 3, high viscosity, 53.9% AcOH) showed practically the same I nos. (1.06, 1.24, 1.11) in spite of their different viscosities.

Acetolysis of bamboo cellulose. SUTEZO OGURI AND MASAAKI NARA. *J. Soc. Chem Ind., Japan* **33**, Suppl. binding 516–7(1930).—Cellulose prepd. by the Cl method from Madake (*Phyllostachys bambusoides*) and Mosochiku (*P. pubescens*, H. Leh.) gave the same yield of cellobiose octaacetate as standard cotton cellulose prepd. by the method of the Cellulose Comm. of the Am. Chem. Soc. The octaacetates obtained from the bamboo celluloses had the same m.-p. and the same $[\alpha]$ as the octaacetate from the cotton cellulose. A. PAPINEAU-COUTURE

Modern steam technic in the cellulose industry. L. V. LAGE MALM. *Svensk Pappers-Tid.* **33**, 833–46, 871–7(1930).—Modern practice favors radiating boilers or vertical tube boilers, water-cooled combustion chambers and pulverized coal as fuel. WILHELM SEGERBLOM

Acetate silk. ETTORE VIVIANI. *Atti III congresso naz. chim. pura applicata* **1930**, 150–9.—A review. E. M. SYMMES

The microstructure of wood tracheids, from observations on the fibrous material of fossil wood. E. OFFERMANN AND G. RUTZ. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 780–6(1930).—Fibers isolated from the cellulose-rich fragments of lignite, designated as "fossil wood," have been studied microscopically, and the structure as altered by swelling in cuprammonium soln. has been compared with that of wood fibers similarly treated. The fibers appear to consist, like those of wood, of layers of spirally wound fibrils. The characteristic swelling behavior (pearl-bead formation, cf. Hess, *C. A.* **24**, 3357) of wood fibers in cuprammonium is not exhibited, however. Apparently the constricting outer membrane, local rupture of which causes this swelling effect, has been destroyed in the process of lignite formation. In many cases the cellulose fibrils have been entirely freed of primary lamella and hemicelluloses, while still retaining their arrangement in the fiber; the views of Hess on the structure of the fiber are thus confirmed. Tests of the isolated and bleached fossil wood fibers gave ash 0.6, α-cellulose 78.0%, no pentosan and relative viscosity in cuprammonium 44–55. Numerous photomicrographs are shown. RANDALL H. DOUGHTY

The fiber structure of lignite. F. LUFT. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 787–91 (1930).—Purified fibers of "fossil wood" (cf. preceding abstr.) gave the Debye Scherrer diagram of native cellulose. From the fiber diagrams of thin lamellas of the lignite, the fibers appear to consist of alternate flat layers of fibrils arranged at ±20° to the fiber axis. Such a structure could be produced by sidewise pressure on a fiber in which the fibrils were spirally arranged in concentric cylindrical layers with alternating direction of rotation. Similar diagrams were obtained from the spines of *Opuntia papyracantha* (a South American cactus) which, like the fossil wood, can be sepd. into concentric lamellas along natural lines of cleavage. RANDALL H. DOUGHTY

The wood research institute of the Eberswalde Technical High School. C. G. SCHWALBE. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 791–4; *Wochbl. Papierfabr.* **61**, 1521–6 (1930).—Equipment and work are described. R. H. DOUGHTY

Studies on the barking of (pulp) wood, with especial reference to the Thorne barker. HANS G. KLEIN AND EGON KURZHALS. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 645–53, 661–9, 678–81(1930).—Extensive expts. are reported covering in detail the power requirements, personnel, efficiency and losses for hand, knife and Thorne barking of pulpwood. The barking loss varies from 15 to 20%, depending on method, operator and the nature, quality and size of the wood. RANDALL H. DOUGHTY

The influence of scientific investigation on pulp production in the last fifty years. K. G. JONAS. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 741–4; *Wochbl. Papierfabr.* **61**, 1458–63(1930).—General. RANDALL H. DOUGHTY

Central-Asiatic reed (Pragmites communis) as a raw material for pulp. N. L. KARAVAEV AND I. M. KRIVOVYAS. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 654–6(1930).—Analysis of the air-dry stalks gave moisture 8.5, ash 5.6, cellulose 42, and lignin 28%. Pulping for 8–9 hrs. at 6 atm. with 10% NaOH soln. (quantity not stated) gave pulp of fair phys. quality 36, analyzing cellulose 90, pentosans 7 and lignin 1.5%. A bibliography is included. RANDALL H. DOUGHTY

Cornstalks in paper making. JOSEPH ROSSMAN. *Paper Trade J.* **91**, No. 23, 51–4 (1930).—A review of U. S. patents. A. PAPINEAU-COUTURE

Alkaline pulping reactions of the long-leaf pine. HARRY F. LEWIS AND EDWIN R. LAUGHLIN. *Paper Trade J.* **91**, No. 25, 57–60(1930).—Long-leaf pine meal (40- to 60-mesh) was extd. with alc. and C_6H_6 to remove resins and was studied in the same manner and, as nearly as possible, under the same conditions as Bray used to investigate the alk. cooking of spruce wood (*C. A.* **23**, 974), except that the present investigation was extended to include cooks at 200°. The relationships established from the exptl. data checked closely those of Bray for spruce. It is suggested that the rather sudden

increase in the "lignin" content of the pulp, when cooking at 200° is carried beyond 2 hrs., is possibly due to the formation at high temps. of cellulose-lignin condensation products which are stable toward 72% H_2SO_4 and therefore appear as lignin in the analytical method. A. PAPINEAU-COUTURE

White papers from Southern pines. I. Pulping loblolly pine for strong, easy-bleaching sulfate pulp. C. E. CURRAN AND M. W. BRAY. *Paper Trade J.* 92, No. 1, 47–52(1931).—The sulfate process was modified so as to make it adaptable to loblolly pine for the production of an easy-bleaching pulp of good strength. The best results were obtained by cooking about 2.5 hrs. at a max. temp. of 170° with a cooking liquor contg. a relatively high ratio of chemical to wood, provided the concn. of the chemicals was maintained at a low value. The kraft pulp thus produced can be bleached to a fair degree of whiteness in a one-stage treatment with 20 5% of bleaching powder; it can be bleached so well that the resulting pulp, having a strength factor of 0.7 point, may be used in various com. grades of paper. It can also be bleached without loss in strength, to a relatively high degree of whiteness in a 2 stage treatment by a modified method consisting of a chlorination followed by a Ca hypochlorite bleach; the resulting bleached pulp can be used for the production of high-grade, strong white papers **II. A modified bleaching process for easy-bleaching sulfate pulps.** C. E. CURRAN, R. H. DOUGHTY AND M. W. BRAY. *Ibid* 92, No. 2, 45–52.—Work carried out on pulps produced by the modified sulfate process described in the previous paper showed that: (1) Bleaching with hypochlorite alone in one stage caused considerable degradation of the pulp. (2) Bleaching with hypochlorite in 2 stages resulted in decreased bleach consumption but in no improvement in pulp quality. (3) The use of various extn. treatments did not produce any change in the foregoing results. (4) The use of Cl water in place of bleaching powder in the 1st stage of a 2-stage bleaching resulted in a decreased bleach consumption and in marked improvement in pulp quality. (5) Optimum results were obtained when the Cl used in the 1st stage was kept between 45 and 50% of the total bleach requirement, which narrow optimum range is apparently peculiar to the specially cooked pulps used and would be different for other pulps. (6) Addn of small quantities of Na silicate during bleaching of the chlorinated pulps had a beneficial effect on the final color but increased the time of bleaching. A. PAPINEAU-COUTURE

Wood-pulp testing for fine-paper mills. S. R. H. EDGE. *World's Paper Trade Rev.* 94, 1818–22, 1874, 1876, 1966–72, 2148–62; *Paper Mill* 53, No. 52, 16–7, 20–1(1930).—A description is given of the changes made in the wood-pulp testing for the fine-paper mills of the Wiggins Teape and Alex. Pirie groups as a result of the work of the pulp evaluation comm. of the Technical Section of the Papermakers' Assoc. of Gt. Britain. The initial-strength test alone is practically valueless for fine-paper mills; the pulp is therefore subjected to treatment for a definite no. of revolutions (13,500) in a Lampen ball mill and the strength again detd. Though the beaten-strength value thus found is not the same as that obtained in the paper mill, comparison with the initial strength indicates in a general way, though not completely, the behavior of the pulp on beating. During 2 yrs. of application in the mills, it has been particularly successful in finding pulps for special purposes and in preventing the waste which accompanies a mill trial of a pulp really inferior to that normally used for any particular paper. The Lovibond tintometer was found the most satisfactory instrument for measuring the color of the pulp, both unbleached and after bleaching under standard conditions with 10% bleach. The discussion of the members present at the reading of the paper is reported. A. PAPINEAU-COUTURE

Pulping and paper-making properties of selected New Zealand woods. C. E. CURRAN, P. K. BAIRD, E. R. SCHAFER, W. H. MONSSON, G. H. CHIDESTER AND A. R. ENTRICAN. *New Zealand State Forest Service Bull.* No. 6, 100 pp.(1930).—The report presents the results of a study at the U. S. Forest Products Lab. of the following 6 New Zealand grown woods, the 1st 2 being indigenous and the last 4 being introduced softwoods: rimu (*Dacrydium cupressinum*), a softwood; tawa (*Beilschmiedia tawa*), a hardwood; insignis pine (*P. radiata*) (Monterey pine); Corsican pine (*P. laricio*); Austrian pine (*P. austriaca*) and European larch (*Larix europea*). The fiber lengths and diam. of the different species are tabulated, and photomicrographs of typical pulp fibers of the various woods are given. The New Zealand softwoods fibers are similar to those of American softwoods. Tawa, however, has a shorter fiber than American hardwood fibers and has a low ratio of length to greatest cross-sectional dimensions. In chem. compns., the New Zealand pines are similar to the American northern jack pine (*P. banksiana*), and rimu, which is not a true pine, is also similar to jack pine. Insignis pine possesses certain characteristics of both jack pine and spruce. European larch corresponds closely to the western larch (*Larix occidentalis*) of the U. S. Tawa

is similar in chem. compn. to sugar maple (*Acer saccharum*). In general, groundwood pulps from insignis pine were equal to spruce in strength, but inferior in color and cleanliness. Elimination of the pith or core rot in the growing tree by appropriate mycological and sylvicultural control would reduce the dirt count materially. The power requirements for grinding insignis pine are relatively greater than those for spruce. Tawa, being a hardwood, produces a mech. pulp much inferior to spruce in strength but of excellent color and comparatively free from dirt. The indicated power requirements per ton were not excessive, and the possibilities of the fiber as a filler are good; a comparatively sharp stone should be used to minimize the loss of fine material in the white water. Insignis pine can be reduced to a suitable quality of sulfite pulp for use in newsprint without bleaching, the yields and strength quality being comparable with those of white spruce sulfite, although not entirely equiv. to this pulp in all respects. Young, immature timber is preferable to older timber contg. heartwood Immature tawa can be readily pulped by the sulfite process, the nature of the product being detd. by the cooking methods used. By using a $10^1/_2$- or 11-hr. cooking schedule, a satisfactory, easily bleaching pulp for book paper can be produced. Reduction of the total time to about 9 hrs. can give a high yield of news-grade sulfite. Mature tawa can also be pulped by the sulfite process but requires special processing. The cooking conditions for immature insignis pine and tawa are similar, and mixts. of the 2 woods can be pulped without difficulty. Rimu can be readily pulped by the sulfite process and, while the product is too dark for use in newsprint in the unbleached state, it can probably be used in such products as glassine, wrapping paper and specialties. European larch, like the North American larches, is difficult to pulp by the standard sulfite process, and the product is of doubtful value. Tawa is suitable for pulping by the soda process and is adapted to the manuf. of a bleached pulp for book or similar grade paper production. The sulfate process can be readily applied to rimu, or to any of the pines, or European larch, and a pulp produced comparing favorably with the so-called No. 1 kraft pulps on the American market. Of the several species, rimu yielded the most satisfactory pulp from the standpoint of strength. The application of the semi-kraft process to rimu, insignis pine and European larch showed that savings in chemicals and increased yields are possible at some sacrifice of pulp strength and appearance by the use of this method. The expenditure of addnl. power in beating semi-kraft pulps would result in materially increased strength. The application of the semi-chem. process to tawa was only moderately successful in its principal objective of producing newsprint, but the strength developed in these pulps by continued rod-mill treatment indicated possibilities in the way of wrappings, boards and other products. In the semi-com. paper-making tests, mixt. of insignis pine groundwood and insignis pine sulfite furnished papers that were stronger than the av. for American newsprint, but were yellower and dirtier. These papers ran well on a modern newspaper press. Both semi-com. and com. paper mill trials showed that a furnish of 20% insignis pine sulfite with 50% tawa sulfite and 30% tawa groundwood can be converted into satisfactory newsprint, with standard mill equipment, at speeds of 300–450 ft. per min. A certain amt. of beating is necessary to reach the required strength quality in tawa sulfite, and a refining effect, such as rod-mill treatment, is necessary for the elimination of shives. The same pulps can be used also in the production of machine-finished book (rotogravure) and dry-finished wrapping papers. Bleached European larch can be substituted for the insignis-pine sulfite in the above mixed softwood-hardwood furnish in approx. the same amt. to produce a satisfactory news sheet. Bleached rimu also can be substituted for insignis-pine sulfite, but it would probably be necessary to use a greater amt. to give the required strength. Tawa cooked by the semi-chem. process did not produce an entirely satisfactory newsprint but may possibly be used to some extent in a news furnish. A. PAPINEAU-COUTURE

Determining the strength of pulps. K. G. JONAS. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 800–5; *Wochbl. Papier-Fabr.* **61**, 1526–34(1930).—In continuation of earlier work (*C. A.* **24**, 3362) a milling and sheet-forming app. for testing pulp with analytical precision has been developed. The milling app. is constructed to operate by centrifugal force. A complete test beating can be performed in a short time, and duplicate tests check to within 3%. The sheet machine, of rectangular form, is specially designed to secure thorough mixing of the stock and a reproducible draining of stock on the wire. The test sheet, couched on a fiber board, is pressed with a loaded roller, this being considered more reproducible than flat-plate pressure. Sheets, on the basis of the tensile test, are reproducible within 1 or 2%. In a general discussion the importance of taking into account both beating time and freeness in connection with a beating strength test is emphasized. The presence of a max. in the strength-basis wt. curve

is shown, and it is recommended that all test sheets be made of the crit. wt. (90 g./sq. m.).
RANDALL H. DOUGHTY

A new method for the determination of mechanical pulp. AUGUST NOLL AND FRITZ HOLDER. *Papier-Fabr.* **28,** Tech.-Wiss. Teil, 700–2(1930).—Various methods of detg. the mech. pulp content of mech.-chem. pulp mixts. are discussed, and a volumetric method is described, which gives results accurate to ±5%. A 4-g. pulp sample is treated with $KMnO_4$, and the mech. pulp content estd. from the $KMnO_4$ consumption with the aid of a prepd. table for which, as well as for details of the method, the original must be consulted. A correction must naturally be made for ash content if this is very high, and any dye present must be destroyed. The results agree well with those of the microscopic method, and the operation is very much simpler. R. H. DOUGHTY

The Roe-Genberg chlorination number of pulp. F. H. YORSTON. *Research Notes* **2,** 21–2(1929).—Failure to sweep all the air out of the pulp chamber when introducing Cl, unavoidable irregularities in temp. control, variations in the soly. of Cl in the water moistening the pulp due to changes in temp. and pressure, and vol. changes due to evapn. or condensation of water are factors which have less effect on the results than the distribution of the pulp inside the pulp chamber. This last factor dets. the rate of soln. of Cl in the moisture present, and hence in the "blank," and seems to be the factor which limits the accuracy of the method; some definite technic for prepg. the pulp samples should therefore be adopted and adhered to throughout any one investigation. If allowance is made for differences in the blank, the amt. of Cl absorbed by a pulp is independent of the partial pressure of the Cl. The reliability of the method was checked by detg. the chlorination nos. of mixts. of bleached and unbleached sulfite and bleached sulfite and groundwood; the relation between compn. and Cl no. was linear, in agreement with Genberg and Houghton (*C. A.* **23,** 4065). A. P.-C.

Microscopy in process control and the need of courses in microscopy. C. G. SCHWALBE. *Papier-Fabr.* **28,** Tech.-Wiss. Teil, 809–10; *Wochbl. Papier-Fabr.* **61,** 1622–4 (1930).—Microscopic control of pulp beating might develop considerable value if observers were properly trained. RANDALL H. DOUGHTY

Beater room control. A. J. WILDMAN, JR. *Paper Mill* **53,** No. 49, 5, 27–8(1930).—The beating-control system used at the mill of the Becket Paper Co. is based on the fact that, with a given roll pressure, the freeness of the stock drops by equal amts. in equal time intervals; as the av. time of beating in this mill is $2^3/_4$ hrs., a freeness test is made 2 hrs. after furnishing, which gives sufficient time to decide on the disposal of a beaterful that has not been properly beaten. Sizing is controlled by means of p_H detns., which obviates accidental omission of size or alum from the furnish. The operation of the control lab. is briefly described, and the benefits derived from beater control are outlined.
A. PAPINEAU-COUTURE

The beating of wood pulp in laboratory and mill. I. The determination of beaten strength. H. AINSWORTH HARRISON. *World's Paper Trade Rev.* **94,** 1988–94, 2060–6, 2104–10(1930).—A detailed description is given of the method used in the lab. of the Cooke & Nuttall mill for evaluating the beaten strength of pulp. Over 80 pulps (mostly kraft and sulfite) tested by this method showed no variation from mill experience. *Procedure.*—Soak for 4 hrs. 4 24-g. (oven-dry basis) lots of air-dry pulp (moist pulps need not be soaked), dil. to 4 l. with H_2O at 15–20°, disintegrate as described in the 1929 report of the pulp evaluation committee of the Technical Section of the Papermakers' Assocn. of Gt. Britain (*C. A.* **23,** 3087, 5576), conc. each lot through a 200-mesh sieve to 3% consistency (800 cc.), and beat in the large Lampen mill (10-kg. bronze ball) for the no. of revolutions equiv. to periods of 15, 30, 60 and 120 min. if a sulfite pulp, and to 30, 60, 120 and 240 min. if a kraft pulp, with the mill running at 300 r.p.m., no adjustment of the p_H being made; dil. the beaten stock to 2 l., clear from lumps by disintegration for 7500 revolutions and dil. to 10 l. Det. Schopper-Riegler wetness in triplicate on 833 cc. of stock (2.0 g. fiber) dild. to 1 l., no corrections for fiber content and temp. variations being required. Make 6 sheets from each lot of beaten stock, using 500 cc. of dild. stock (1.2 g. fiber) and following the procedure of the pulp evaluation comm.; retain 1 sheet as a sample; condition the other 5 at least 4 hrs. (preferably 12–8 hrs.) at 65% relative humidity; test for bursting, tensile and tearing strength, stretch, basis wt. and apparent sp. gr. as described by the pulp evaluation comm., and air permeability by the Gurley densometer. Each property is plotted against time of beating. In order to have a single value to express the strength properties of pulp, the *strength factor* is calcd. from (bursting factor multiplied by 2) + (breaking length/100) + (tear factor/5), a value being given which, though arbitrary and empirical, represents the 3 kinds of strength in something like their relative importance in H.'s mill. The *pulp value* is the strength factor (corrected to 65% relative humidity) of a pulp at 40° Schopper-

Riegler. The *time value* is the time in min. taken to reach a wetness figure of 30° Schopper-Riegler. The *paper value* is calcd. from the results of the tests carried out on the paper in the same way as the strength factor of the pulp. When an abridged test is required, fairly accurate results may be obtained by carrying out only one beating operation, provided it is for such a period that the max. wetness value met with in mill practice is reached or passed. Single beating tests may be relied on to give results within 4–5% of each other, and by conducting a series of beating operations for different periods the limit of error is probably not more than 2–3%. The *drainage time* (time in sec. required for the standard column of water on the sheet-making machine to disappear) is an important property which gives valuable information regarding the condition of beaten stock; it shows markedly the changes taking place in the character of the pulp at high degrees of wetness, of which the Schopper-Riegler beating tester gives only slight indication; it also differentiates between the rate of drainage of a mech. pulp and of a beaten chem. pulp, both of which may have the same Schopper-Riegler wetness but which would work differently on the paper machine wire. Ordinary changes in temp. of the water entering the sheet machine produce appreciable variations in the bursting strength, which increased with decreasing temp.; this possibly confirms the impression of many paper makers that paper made in winter is stronger than that made in summer. The av. of 200 readings showed that the bursting strength is 1.4% lower when the detn. is carried out with the glazed side of the sheet down. II. *Ibid* **94**, 2241, 2244–50, 2336–40(1930).— Data are submitted to indicate some of the possible applications of the Lampen mill in conjunction with the British standard sheet-making equipment to the solution of phenomena of practical and theoretical interest in paper mill operations. Two kraft pulps made from the same wood, one cooked normally and the other overcooked, had the same rate of increase of wetness on beating, but the latter had a more rapid rate of increase in strength though the max. strength was lower. On aging (6 months) the bursting and tensile strength of both pulp and paper fell off appreciably; the tearing strength was unaltered in the pulp, but somewhat lower in the paper. On beating dry kraft pulp at 100° for 20 hrs., soaking 4 hrs. and beating for 30 min., the bursting and tensile strengths were much reduced and the tear was increased. A comparison of the behavior of moist (55% H_2O) and air-dried pulp showed that: (*a*) the greatest difference in strength between moist pulp and the same pulp when air-dry occurs in the unbeaten state; (*b*) air drying of pulp does not result in an irreversible colloidal change of fiber surface, since by adequate beating air-dried pulp develops equal strength to the same pulp kept moist; (*c*) dry pulp increases in strength much more rapidly than moist pulp during the first few min. of beating, the regain in strength being approx. equiv. to that lost during the drying process; (*d*) moist pulp does not increase in wetness (Schopper-Riegler degrees) more rapidly than dry pulp, provided the latter has been soaked 4 hrs. Results of a preliminary investigation on the blending of pulps showed that, as regards wetness, strength and especially drainage time and air permeability, the values for the blended pulp cannot be calcd. from the values for the components. A study of mill-beaten and mill-refined stock, before and after subjecting to lab. beating, showed that: (*a*) refining contributes about the same wetness effect as lab.-beating, (*b*) lab.-beating decreases stretch considerably more than does refining; (*c*) refining produces appreciable increase in wetness only at the expense of tear; it greatly increases resistance to air penetration. The difference between lab. sheets made from mill-refined stock and the mill paper made from the same stock must be due to the conditions to which the stock is submitted during its passage from the machine chests to the reel end of the paper machine; in one example, the mill paper was 31.4% weaker in burst, 25.3% weaker in tensile, and 20.4% stronger in tear than lab.-made paper of about the same substance no. It would seem that the pulp disintegrater and Lampen mill together may be considered as the lab. equiv. of the mill beater and refiner, but with the following 3 main differences: (1) The lab. method produces a fall in tearing strength at a Schopper-Riegler wetness at which the tearing strength may still be increasing in the mill. (2) It produces a greater reduction of fiber length with consequent decrease in tear; the more or less irregular formation of mill paper may also produce a higher tear than those having the best formation possible on the sheet machine. (3) Even under the most favorable conditions, during mill beating it is not possible to treat all the fibers alike; some fibers escape the action of the roll completely, while others are extensively damaged. The strength of pulp after beating 1 hr. in alc. was but very little more than the unbeaten strength (the actual increase is probably due largely to the imbibition of H_2O with which the fibers came in contact after the beating operation in the formation of the sheet), while the cutting was greater than that after 17 hrs.' beating in water. In an attempt at analyzing

the fundamentals of the strength of paper, H. discusses the 4 factors which he considers as primarily influencing paper formation, hydration and strength: felting, fibrillation, surface cohesion and individual fiber strength. A. PAPINEAU-COUTURE

Effect of beating upon certain chemical and physical properties of pulps. C. E. CURRAN, F. A. SIMMONDS AND H. M. CHANG. *Ind. Eng. Chem.* **23**, 104–8(1930).—The chem. constitution of a stuff beaten 4 to 6 hrs. in an approximately neutral water suspension was found to be the same as that of the unbeaten pulp. A slight oxidation of the cellulosic constituent in the sulfate pulp was indicated, possibly caused by alkali adsorbed from the digestion liquor. An apparent correlation between the hydrolysis number and the corresponding tearing-strength factor was observed. The results of the fiber measurements, in conjunction with the strength tests, indicated that, aside from the surface conditions of the fibers, the max. strength of a paper depends upon an optimum ratio of relatively large to small particles. F. A. SIMMONDS

The grinding and beating process. LUDWIG E. WALTER. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 677–8(1930).—The conception that all the energy put into these processes is transformed into heat, though persistent, is erroneous. A part, though so small as to escape measurement with present methods, goes into the formation of new fiber surfaces. The increase of surface is the object of grinding and beating operations, and any means by which this can be accomplished with less loss of energy as heat will result in increased efficiency of the processes. RANDALL H. DOUGHTY

α- and β-Ligninsulfonic acid. PETER KLASON. *Svensk Pappers-Tid.* **33**, 791–2 (1930); cf. *C. A.* **24**, 3358.—K. takes exception to some of the statements by Hägglund on this topic (cf. *C. A.* **24**, 5152) and refers to some of his own work to support his objections (cf. *C. A.* **22**, 1361, 1680, 2147). WILHELM SEGERBLOM

Advances in burning sulfite waste liquor. J. HAUSEN. *Papier-Fabr.* **28**, Tech.-Wiss Teil, 632–4(1930).—Data are presented showing that 27° Bé. liquor can be burned successfully with coal by spraying. The cost of concg. liquor of less than 9° Bé. is, however, greater than the profit on the steam generation. Concn. of the liquor with waste furnace gases appears promising. RANDALL H. DOUGHTY

Some problems of the German sulfite pulp industry. DEUTSCH. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 778–80(1930).—The general problem of wood supply might be solved by application of the sulfite process to new species better than by attempts to develop new processes. To do this efficiently requires study of heat economy in pulping, of the mechanism of the pulping reactions and of bleaching. The development of some outlet for waste liquors large enough to be economically important is also a very pressing problem. RANDALL H. DOUGHTY

The Albenielsen sulfate pulping process. MARQUARD H. LUND. *Paper Trade J.* 91, No 26, 53–5(1930).—The essential feature of the process resides in a cylindrical evaporator in conjunction with the digester. One evaporator can serve 1 or 2 digesters. The merits of the process are briefly discussed. It is claimed that the process can be adapted to sulfite cooking. A. PAPINEAU-COUTURE

The sedimentation of causticizer mud in the sulfate pulp process. BO. WIESLER. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 559–60(1930).—SiO_2 from straw pulping or from siliceous limestone, and FeS, are mentioned as causes of slow settling of causticized liquor. Heating to as high a temp. as possible speeds the settling. R. H. D.

General analysis of (sulfate) black liquor. FRANCIS J. CIRVES. *Paper Trade J.* 91, No. 19, 55–6(1930).—A scheme of analysis is outlined, comprising the following detns.: partial, total and active alkalies, Na_2CO_3, total and partial I values, Na_2SO_3, $Na_2S_2O_3$, Na_2S, NaOH, total solids, ash, combustible non-volatile org. matter, alky. of ash, NaCl, SiO_2, fats + resins + lignins, oxyacids + saccharides + lactones, fatty acids, resins, alc.-sol. lignin, hot-sol. lignin, insol. lignin and total lignin. An example is given of the results obtained on a sulfate black liquor by the procedure outlined. Most of the procedures are standard, or modified to obtain the most favorable results. A. PAPINEAU-COUTURE

Investigation of sulfate waste liquor. FRANCES J. CIRVES. *Paper Trade J.* **91**, No. 19, 56–8(1930).—Acidification of sulfate black liquor with dil. H_2SO_4 gives a voluminous chocolate-brown ppt. representing about 10% by wt. and 30% by vol. of the liquor, and consisting principally of ligneous matter with some fats and resins. The lignin remaining after removal of the fats and resins can be fractionated as follows: (1) treatment with cold alc. removes lignin I, a brown, amorphous powder, readily sol. in caustic solns. and in NH_4OH, from which it is repptd. by acid with development of a strong humus odor; on 2nd and subsequent repptns. there is a marked vanillin odor; (2) treatment with boiling glacial AcOH dissolves out lignin II, which exhibits great adhesive properties on slight cooling of the soln., has a lustrous reddish brown color,

and behaves much like a gum or resin, as it is sol. in both boiling AcOH and boiling alc.; (3) the residue of lignin III is insol. in strong caustic solns. and in NH_4OH, but readily sol. in very dil. NaOH soln. All 3 forms of lignin are sol. in Me_2CO in the order named. Approx. mol. wt. detns. based on the combining wt. with NaOH calcd. on the basis of both 1 and 2 atoms of Na per mol. of lignin gave for lignin I 862, 431 and for lignin II 536, 268. Lignin III gave a very low value (117) which is possibly due to the fact that its combination with NaOH may be an adsorption phenomenon rather than the formation of Na lignate, since it is insol. in 17.5% NaOH but more sol. on excessive diln. with H_2O, which is conducive to hydration and mol. adsorption. Comparison of the yield and compn. of Mosinee pulp and of the compn. of Mosinee sulfate black liquor and of sulfate and soda black liquors produced by 2 foreign processes (not specified) showed that: (1) about 12% of the original solid content of the wood is lost as volatile compds. in the Mosinee pulping process; (2) Mosinee black liquor has a higher fat and resin content (probably because green wood is used, instead of dry wood in the other 2 processes); (3) the oxyacid and lactone content was 6–8% higher in the Mosinee liquor, but it contained practically no AcOH or formic acid (of which about 9–10% were present in the other liquors, based on the wt. of total solids in the liquor); (4) humic compds. were absent from the Mosinee liquor, whereas they were present in the soda black liquor. The latter fact, together with the practical absence of AcOH and formic acid from the Mosinee liquor, indicates that the process used at the Mosinee mill is milder than the others and produces less decompn. of the incrusting wood substances. A. PAPINEAU-COUTURE

Multi-stage bleaching process. EMIL HEUSER. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 794–800(1930); cf. *C. A.* **24**, 5492. R. H. DOUGHTY

Bleached groundwood pulp. A. O. BRAGG. *Pulp Paper Mag. Can.* **30**, 535–7, 554(1930).—A description of its manuf., properties and applications. A. P.-C.

Bleaching influence on viscosity of soda pulp. J. H. ROSS, C. R. MITCHELL AND F. H. YORSTON. *Paper Trade J.* **91**, No. 20, 53–4(1930).—Results are given of an attempt to utilize the cuprammonium viscosity test (Bialkowsky, *C. A.* **24**, 3366) as a means of fixing the proper set of conditions to be used in arriving at a pulp bleached to a shade desired and estd. by means of optical instruments. The test was found particularly useful in connection with expts. on the influence of H-ion concn. in bleaching exptl. soda pulp. If (as generally believed) the first reaction in ordinary Na or Ca hypochlorite bleaching is an addn. of HOCl to the lignin or coloring matter, the alky of the bleach liquor should increase; the fact that no such increase takes place is attributed to: (1) a balance between 2 phenomena, first, adsorption of alkali by the cellulose, 2nd, addn. of HOCl to the lignin (exptl. evidence is presented in support of this hypothesis); (2) oxidation of incrustants, as opposed to chlorination, in the course of which the alk.-reacting hypochlorites are converted into neutral chlorides; (3) production of acidic compds. during bleaching. Of various procedures studied, the optimum conditions found so far for exptl. bleaching at 2% consistency consisted in a 2-fold chlorination, followed each time by extn. with 0.1 *N* alkali, and followed finally by bleaching at a p_H of 10; so little bleach was required in the final treatment to obtain a good white that the p_H could be kept absolutely fixed by means of the usual *M*/2 borate and phosphate buffers, because the concn. of soda bleach at the low consistency used was small compared with that of the buffer. A. PAPINEAU-COUTURE

Paper-pulp industry on the Pacific Coast. FOLKE-JOHANSSON. *Svensk Papperstid.* **33**, 877–83(1930).—Descriptive and statistical. WILHELM SEGERBLOM

Present problems of paper-pulp production and ways to their solution. ROLAND RUNKEL. *Techn. u. chem. Papier-Zellstoff-Fabr.* **27**, 81–8, 97–110(1930).—One serious problem is that of raw-material supply. Literature on the subject of increased or improved utilization is reviewed, and a *new pulping process* designed to produce a superior yield and class of pulp from inferior wood is described. The process has been tested with spruce, bamboo, pine, oak and beech woods. Detailed data are given for the latter only. Standard beech-wood pulp chips were soaked 4 hrs. in 2% NaOH at 100°, freed from bark, washed and treated for 2 hrs. more at 100° with 10% of NaOH in 3–3.5% soln. The treated material, after rod milling, gave 80% good pulp and 2% screenings (basis original wood). The pulp was treated with excess Cl_2, in 0.4% NaOH at 6% consistence, given a H_2O and dil. NaOH wash, and again chlorinated (no excess) in 0.1% NaOH at 5% consistence. The final product, of good color and strength, was obtained in yields of 50–55%, as against yields of 30 and 40%, resp., by the standard soda and Mitscherlich sulfite processes from the same wood. R. H. DOUGHTY

Cunninghamia lanceolota for paper making. JOHN B. CALKIN. *Paper Trade J.* 91, No. 22, 53–5(1930).—Results are given of grinding tests and soda and sulfate cooking

tests carried out on *Cunninghamia lanceolota* (Lamb) Hook, from China, known locally as "charm." Grinding in a com. 3-pocket grinder gave a groundwood of very low strength, probably because of the condition of the stone used. Cooking with 28.9% NaOH (on the dry wt. of the wood) at a concn. of 66.3 g. per l., for 4.5 hrs., at an av. pressure of 115 lb. per sq. in. and av. temp. of 170°, yielded 39.7% of pulp having a bleach requirement of 26.4, strength ratio 19.53, relative compactness 2.61, tearing ratio 114.62, and comparing very favorably with exptl. spruce soda pulp obtained under approx. similar cooking conditions. The sulfate cooks did not show any increase in strength over the soda cooks except in one instance where there was an increase in the tearing ratio. The wood contains a good proportion of cellulose, and, by taking into account the slightly higher resin content as compared with spruce, it should give results comparable to those obtained from spruce in com. practice. A. P.-C.

Measurement of average fiber length. JOHN B. CALKIN. *Paper Trade J.* **91**, No. 20, 54(1930); cf. *C. A.* **24**, 5486.—A correction. A. PAPINEAU-COUTURE

Deterioration of the Herzberg stain. F. L. MINNEAR AND JAMES R. WITHROW. *Paper Trade J.* **91**, No. 24, 51–5(1930).—The Herzberg stain, when preserved in a tightly fitting ground-glass stoppered, dark bottle, has a "life" of more than 1 yr. The conclusion of former workers that this can be preserved well for only 2 weeks is therefore erroneous. Slides of rag, sulfite and soda fibers stained with the Herzberg stain may be preserved for about 2 months by paraffining the edges to prevent change in moisture and I content of the stained fibers. The rag fibers "bleach" sooner than either the sulfite or soda. Volatilization of free I from the Herzberg stain is probably the most common cause of deterioration of this reagent. By making up a larger stock batch, which is checked and standardized against known fiber compns., then by drawing smaller portions from it for active use, the possession of a satisfactory stain will be assured. A. PAPINEAU-COUTURE

The use of chlorine for slime elimination [in paper mills]. O. T. BIRKENESS. *Paper Trade J.* **91**, No. 20, 51–2(1930).—Elimination of existing slime and prevention of its formation can be efficiently accomplished by appropriate use of free Cl, the quantities and points of introduction varying widely according to the particular mill conditions. The Cl required per ton of paper produced for different grades is roughly as follows: paper board 1–4, book paper 0.5–2, kraft paper 1–3, tissue paper 1–2, roofing felt 2–5 lb. Accurate control of the treatment should be maintained. The benefits of the treatment are indicated. A. PAPINEAU-COUTURE

The Thyle consistency control. H. L. RAMMER. *Paper Trade J.* **91**, No. 21, 51–3 (1930).—A brief description is given of the principle and operation of the Thyle consistency regulator, with a brief discussion of its merits. A. PAPINEAU-COUTURE

The Fresk digester-filling system. OTTO F. KREISSLER. *Paper Trade J.* **91**, No. 26, 56–8(1930).—A discussion of the disadvantages of ordinary gravity filling of digesters and of packing the chips by stamping, and of the advantages of the use of the Fresk filling system by which the chips are uniformly distributed and packed in the digester. A. PAPINEAU-COUTURE

Direct versus indirect steaming. C. H. CHRISTIANSEN. *Paper Mill* **53**, No. 47, 24, 26(1930).—The relative merits and disadvantages of stationary and tumbling digesters using direct steam are compared with stationary digesters using indirect steam with forced circulation. A. PAPINEAU-COUTURE

Control of acidity improves sizing. BENNETT, LTD. *Pulp Paper Mag. Can.* **30**, 724(1930).—The following p_H values, though not applying equally well in all cases, are generally recognized as being standard conditions giving the most satisfactory results: stock before alum and size are added 6.5–7.5, av. 7.0; white water in tray at paper machine 4.5–6.0, av. 5.0. If the stock is acid before addn. of the size, local coagulation of the size will take place with resulting loss in sizing efficiency, irregular sizing and even size spots. If the stock has a high alky. (p_H 7.5 or more) before addn. of the size, it should be tested for Ca salts, which are very detrimental to sizing. A PAPINEAU-COUTURE

Calibration of Canadian standard freeness tester. W. BOYD CAMPBELL AND W. E. ADLINGTON. *Pulp Paper Mag. Can.* **31**, 750–1(1931).—Instructions are given for maintaining the instrument in condition for accurate work. A. PAPINEAU-COUTURE

Testing the Schopper-Riegler freeness tester, with automatic valve, for uniformity of results. KORN. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 683–7; *Wochbl. Papier-Fabr.* **60**, 1336–41(1930).—A new design of this app. arranged to eliminate the personal equation in opening the drain valve is described. Data are presented for 10 tests made by each of 3 individuals on each of 8 pulps. After correction for variations in sample weight

the greatest deviation from the mean in 10 tests was 1°, while the greatest deviation between the av. values found by the 3 operators was 0.5°. RANDALL H. DOUGHTY

An improved Schopper-Riegler freeness-consistency chart. D. S. DAVIS. *Paper Trade J.* **91**, No. 21, 49–50(1930).—It is shown that the nature of Korn's freeness-consistency data (*C. A.* **23**, 5577) permit the construction of straight-line charts for the purpose of correcting freeness to the standard consistency basis. Two such charts are given. A. PAPINEAU-COUTURE

Paper in the electrical industry. W. H. ANDERSON. *Paper Mill* **53**, No. 52, 11–2, 14(1930).—A general description is given of the various uses to which paper is put in the elec. industry and of the properties of the different grades so used. A. P.-C.

Paper-mill slime. DONALD K. PATTILLO. *Paper Mill* **53**, No. 51, 4, 6, 8, 32 (1930).—A review of the development and operative work during the past 3 yrs. on the elimination and prevention of the formation of slime in paper mills. The benefits of properly controlled chlorination are summarized. A. PAPINEAU-COUTURE

Slime in pulp and paper mills with special reference to methods of prevention. CLARA W. FRITZ. *Research Notes* **2**, 9–10(1929).—A study of slime conditions in 4 Canadian pulp and paper mills showed it was present throughout the groundwood, sulfite and paper-mill systems. The bulk of the slime was usually found to be composed of filamentous fungi of the mold type, which formed a matted tangle in which bacteria, yeasts and unicellular animals were frequently found developing. It originates from the raw materials (particularly the water) and the air carrying spores and viable vegetative fragments from pieces of dried slime and pulp in the mill. The fungi tolerate a wide range of temp. variation (3–19°) and a wide H-ion concn. (p_H 4.6–7.6). $CuSO_4$ and NaOH for preventing slime were found practically useless; some satisfactory results were obtained in certain cases with Cl. Treatment of the piping, etc., with NaOH, followed by flushing with clean water, removes the slime. A. P.-C.

Progress of research on paper making from eucalypts in Australia. J. L. SOMERVILLE. *World's Paper Trade Rev.* **94**, 2329–34(1930).—A brief review of the work done on the paper-making properties of Australian eucalypts (see Benjamin and S., *C. A.* **22**, 3776; **23**, 3089). A. PAPINEAU-COUTURE

The durability of paper. JAMES STRACHAN. *Paper Mill* **53**, No. 51, 12–3(1930).—This is a brief discussion, bringing out the difference between chem. deterioration and mech. deterioration. A. PAPINEAU-COUTURE

Bursting-tester standardization. G. F. UNDERHAY. *World's Paper Trade Rev.* **94**, 2268–78(1930); **95**, 24–8(1931).—Results are given of a comparative study of the Mullen and Schopper bursting testers, sources of errors being shown and remedies for these being suggested. The Schopper tester can be easily improved to obtain a practically uniform rate of pressure increase by fitting it with a Dewrance valve of the type used in conjunction with pressure gages, which should be placed as close as possible to the needle valve supplied by the makers. It is shown that a thin red rubber diaphragm is preferable to that supplied with either instrument; by use of the diaphragm supplied with the Schopper tester it was impossible to record with any certainty a burst of less than 10 lb. per sq. in., while with a thin red rubber diaphragm bursts of 5 lb. could be recorded accurately. A. PAPINEAU-COUTURE

Obtaining efficiency by careful selection of recording instruments. W. O. HERBERT. *Paper Ind.* **12**, 1402–3(1930).—A brief discussion of the importance and advantage of continuously recording the SO_2 content of S burner gases in sulfite mills. A. P.-C.

Chromium plating in the paper industry. D. H. BISSELL. *Paper Ind.* **12**, 1390–9 (1930).—An outline is given of some of the many interesting and highly successful applications of Cr plate, particularly on equipment used in paper manuf. A. P.-C.

The Zeiss photometer in the paper mill. GIRO SYLVIO. *Papier* **33**, 963–74 (1930).—A description is given of the instrument and its operation and of its use for measuring the gloss of paper, for the examn. of fillers and for measuring transparency. A. P.-C.

Surface temperatures and water evaporation on the drying part of a paper machine. FR. MÜLLER AND R. TRENSCHEL. *Papier-Fabr.* **28**, Tech.-Wiss. Teil, 812–9, 825–30; *Wochbl. Papierfabr.* **61**, 1534–44(1930).—Detailed data are presented for a newsprint and a greaseproof machine, the thermal efficiencies of which were found to be 66 and 72%, resp. It is pointed out that in detg. the surface temps. of rotating cylinders an unknown error is introduced by frictional heat. RANDALL H. DOUGHTY

Machine for testing the strength and elongation of a single fiber (AOKI, ATSUKI) **25. Cornstalks as an industrial raw material** (SWEENEY, ARNOLD) **13. Arsenic in writing materials** (KAPPELLER) **26. Recovery of AcOH (Fr. pat. 689,733) 10. Hydrogenation**

processes (cellulose, wood, etc.) (Fr. pat. 691,303) **21.** *tert*-Butylnaphthol [as plasticizer for cellulose derivatives] (U. S. pat. 1,788,529) **10.** Producing designs on surfaces composed of cellulose derivatives (Fr. pat. 689,007) **5.**

Cellulose. ALBERT E. NIELSEN. Fr. 689,245, Feb. 1, 1930. An app. is described for making cellulose from wood, etc., by the indirect application of steam and circulation of the cooking liquid outside the oven.

Cellulose. ERNST SCHMIDT. Fr. 689,291, Nov. 30, 1929. Cellulose is obtained from wood, etc., particularly woods which are not easily dissolved by the ordinary process, by adding to the sulfite lye metals such as Fe, Ag, Cu, Al, Zn, Sn, Pb, Co, Ni, Cr, Mn or their salts or oxides.

α-Cellulose. LAURI I. L. DURCHMAN. Can. 397,799, Jan. 20, 1931. α-Cellulose is produced by cooking wood chips with black and white sulfate liquor with the addn. of Na_2SO_3 in the proportion of 0.8–1.0% based on the air-dry wt. of the wood chips, boiling the resultant pulp under atm. pressure with a mixt. contg. NaOH and NaCl, bleaching, treating the bleached pulp at room temp. for 3–6 hrs. with a 5–12% soln. of NaOH, recovering the NaOH, washing and treating with oxalic acid to neutralize the residual alkali and to facilitate extn. of other residual and coloring impurities. Cf. *C. A.* **25,** 204.

High-grade α-cellulose. LAURI I. L. DURCHMAN. Can. 307,798, Jan. 20, 1931 Incrusting substances of wood pulp are converted into water-sol compds. by treating the pulp for 4–6 hrs. at 20 to 60 lb. pressure with a soln. contg. 2–5% NaOH and 1–3% Na_2SO_3, bleaching, treating the bleached pulp at room temp. for 3–5 hrs. with white liquor to effect removal of incrusting substances for obtaining a high-grade α-cellulose, treating the pulp with oxalic acid to ppt. the Ca compds. and to dissolve the Fe compds and washing the pulp to remove the Fe and Ca compds.

Straw cellulose. V. P. TELEZHKIN. Russ. 43,202, Mar. 21, 1929. Straw cut into small pieces is treated at 50° with a soln. of compds. obtained by a sulfonation of fusel oils together with naphthalene. The boiling is then carried out in rotating containers and in caustic.

Saccharification of cellulose. SOC. ANON. DES DISTILLERIES DES DEUX-SÈVRES. Fr. 691,350, May 14, 1929. Cellulose in the form of waste wood, etc., is saccharified by converting it into cellulose formates by treatment with HCOOH and hydrolyzing the formates obtained, this hydrolysis being completed by boiling in aq. soln. in the presence of a mineral acid with or without pressure. Cf. *C. A.* **24,** 3112.

Cellulosic materials. HENRY DREYFUS. Fr. 36,935, May 18, 1929. Addn. to 675,354 (*C. A.* **24,** 2880) Cellulosic materials are made more apt to react in view of esterification in 2 steps by treating the materials with one or more org. acids applied alone or mixed with inert diluents and then treating them with one or more org. acid anhydrides and (or) one or more org. acids. A condensation agent may be added during the 2nd step and is neutralized before the end of the step.

Decomposing cellulosic substances. OSKAR A. MULLER. Fr. 689,624, Feb. 8, 1930. Substances contg. lignin and cellulose are decomposed by chlorination in the moist state. The chlorolignin is liberated by treatment with an org. solvent contg. a mineral acid and miscible with water. The cellulose is isolated from the elements sol. in the org. solvent, after which the chlorolignin is sepd. from the ext. obtained, the solvent is removed by distn., the tanning substances are isolated by extn. and the aq. residue is submitted to a fermentation.

Method and plant for dewatering packed cellulose, etc., with a number of presses. J. M. VOITH MASCHINENFABRIK. Ger. 512,379, May 16, 1925.

Cellulose products. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 690,215, Feb. 19, 1930. Benzylcellulose is modified so that it gives clear solns., and the viscosity of its solns. is diminished by treating it with $C_6H_5CH_2Cl$ or other aralkyl halide and with water and steam at ordinary or increased pressure. Further, a reaction mass obtained by the action of $C_6H_5CH_2Cl$ on ripened alkali-cellulose, the esterification taking place in a single phase without isolation of the intermediate products, is purified until it contains 3–25% of $C_6H_5CH_2Cl$ or other aralkyl halide, the latter being transformed into aralkylalc. The processes give *lacquers* which dry with a polished surface.

Cellulose films. LA CELLOPHANE. Fr. 689,072, Jan. 29, 1930. Cellulose films which are more or less opaque and more or less mat are made by producing or incorporating in the film or in the starting material, either a finely divided inert solid or a liquid capable of forming a stable emulsion with the viscose or an insol. compd. when treated with appropriate reagents.

Cellulose derivatives. CAMILLE DREYFUS. Fr. 689,134, Jan. 30, 1930. Cellulose

esters such as the acetate are fractionated by a fractional pptn. of their solns. Thus, water or other nonsolvent may be added to a soln. of cellulose acetate in a mixt. of C_6H_6 and EtOH or MeOH, or the soln. may be fractionated by cooling.

Cellulose derivatives. HENRY DREYFUS. Fr. 36,814, Mar. 23, 1929. Addn. to 671,921 (*C. A.* **24**, 2290). Mixed derivs. of cellulose are made by treating cellulose materials so as to replace a part of the OH groups by alkacyl groups and another part by alkoxyalkacyl groups, *e. g.*, by means of Ac_2O and methoxy acetic anhydride. Metallic chlorides or H_2SO_4 may be used as catalysts. The products have their solubilities changed by treating them in soln. or suspension with org. or inorg. acids, acid salts, salts having an acid reaction or aromatic amines or their salts.

Cellulose derivatives. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 689,557, Feb. 7, 1930. New cellulose derivs. are prepd. by the action of halides of cyanohydric acid on cellulose rendered active. An alkali cellulose prepd. by treating cellulose with alc. solns. of KOH may be used. A treatment with CS_2 may take place before or during the treatment with the halide, and the treatment may take place in the presence of org. bases, or the reaction products are submitted to the action of water, bases or alcs. Cf. *C. A.* **25**, 812.

Compositions containing cellulose derivatives. I. G. FARBENIND. A.-G. Ger. 512,321, July 25, 1925. Aliphatic esters of maleic and fumaric acids are used as solvents or softening agents for cellulose derivs., alone or with other solvents, diluents, etc. Examples are given.

Cellulose acetate. COURTAULDS, LTD. Ger. 512,225, April 6, 1927. See Brit. 269,012 (*C. A.* **22**, 1473).

Cellulose acetate. ALEXANDER WACKER GES. FÜR ELEKTROCHEM. IND. G. M. B. H. (Wolfgang Gruber, inventor). Ger. 510,425, Jan. 10, 1926. Cellulose acetate insol. in acetone is converted into the acetone-sol. form by treatment at a temp. below 30° with chloroacids contg. water of crystn. and derived from bivalent metals of the first or second periodic group. Suitable acids are $HZnCl_2$ $2H_2O$ and $3HgCl_2.4HCl.14H_2O$. Other acids or neutral salts may be added with the chloro acids. Examples are given.

Cellulose acetate. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 689,200, Jan. 31, 1930. Cellulose acetate is prepd. by submitting cellulosic material to a preliminary treatment, *e. g.*, to the action of AcOH, and distg. the mixt. in the presence of a liquid which forms an azeotropic mixt. with water, such as ethylene chloride, to remove the water from the mixt. and afterward continuing the esterification of the cellulosic material.

Composition cellulose acetate films, etc., for tipping cigarets. C. MÜNCH. Brit. 334,271, April 4, 1929. A non-transparent composite film comprises a very thin layer in which the color or pigment, if any, such as bronze powder, is in such limited proportion as not to destroy the waterproof character of the film, and another very thin layer contg. sufficient finely divided pigment to render the layer non-waterproof and to give it a mat surface. Various details of manuf. are described.

Cellulose esters. SOC. DES USINES CHIM. RHÔNE-POULENC. Fr. 689,244, Feb. 1, 1930. Sol. cellulose esters of carboxylic acids contg. at least 8 atoms of C in the mol. are made by treating cellulose or its near transformation products with the anhydrides of the acids in question in the presence of a catalyst composed of sulfo derivs. of aliphatic hydrocarbons such as methanesulfonic acid and in the presence or not of diluents. Cf. *C. A.* **24**, 2290, 5495.

Cellulose esters. SOC. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 690,115, Feb. 17, 1930. Mixed cellulose esters are prepd. by digesting an aryl ester of cellulose, such as the acetate, with an aliphatic or aromatic mono or dibasic acid contg. an OH group in the α-position, such as lactic, tartaric, racemic, glycolic, glyceric or malic acid. Cf. *C. A.* **25**, 813.

Cellulose esters. SOC. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 690,458, Feb. 22, 1930. Mixed cellulose esters are made by digesting an acyl ester of cellulose, such as cellulose acetate with an acid contg. a keto group in the α- or γ-position, such as pyruvic, α-ketobutyric, α-ketovaleric, α-ketocaproic or levulinic acid. Cf. *C. A.* **25**, 813.

Cellulose ester compositions. SOC. DES USINES CHIM. RHÔNE-POULENC. Fr. 691,337, May 21, 1929. Films, etc., are made of cellulose acetate to which tri(*m*-hydroxyphenyl) phosphate is added as a plastifying and fireproofing agent.

Cellulose ester films. SOC. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 689,574, Feb. 7, 1930. Films of cellulose esters which do not shrink are prepd. by submitting the film to a drawing while in a swollen state and drying it while drawing. An app. is described.

Mottled plastic products from cellulose ester compositions. DANIEL D. PAYNE (to du Pont Viscoloid Co.). U. S. 1,789,081, Jan. 13. Various details are described of assembling and subdividing bundles of units of differently colored material.

Cellulose ester and ether products. SOC. POUR LA FABRICATION DE LA SOIE RHODIASETA. Ger. 512,160, Feb. 17, 1925. Artificial filaments and films are prepd. by dissolving a cellulose ester or ether and an albuminous material in an aq. soln. of one or more derivs. of thiocyanic or isothiocyanic acid and coagulating the soln. in an aq. bath which may contain a neutral salt, *e. g.*, Na_2SO_4. Before the soln. is spun, it may be allowed to ripen and then made alk. by addn. of NH_3 or an org. base. The method is particularly useful with cellulose formate.

Cellulose ether-esters. I. G. FARBENIND. A.-G. (Ernst Teupel, inventor). Ger. 510,424, Jan. 21, 1928. An alkyl cellulose contg. not more than 1.5 alkyl groups is acylated in the presence of a small quantity of a catalyst so as to yield a product in which a total of 2–2.5 OH groups of the cellulose mol. ($C_6H_{10}O_5$) are substituted. The amt. of catalyst does not exceed 0.5% when H_2SO_4 is used. The products are useful for making films, lacquers, etc. Examples are given. Cf *C. A.* 25, 104.

Cellulose ether products. I. G. FARBENIND. A.-G. (Kurt Sponsel and Gerhard Balle, inventors). Ger. 509,304, Aug. 13, 1925. Films, filaments, etc., are prepd. from water-sol. alkyl ethers of cellulose by extruding their aq. solns. into hot water.

Cellulose ether solutions. I. G. FARBENIND. A.-G. (Hans Persiel, inventor). Ger. 509,067, Mar. 18, 1927. Solns. contg. a water-sol. cellulose ether and a tanning agent are prepd. with an aq. org. solvent. Thus, an aq. soln. of methylcellulose may be mixed with an alc. soln. of tannin, or methylcellulose may be dissolved in a soln. of tannin in aq. propanol. The solns. may contain albumins, resins, etc., and may be used for making coatings, filaments, etc. Cf. *C. A.* 25, 592

Cellulose ether solutions and plastics. GERHARD STEIMMIG (to I. G. Farbenind. A.-G.). U. S. 1,788,781, Jan. 13. A cellulose ether such as ethylcellulose is used with a monoaryl ether of ethylene glycol such as the monocresyl ether and with other solvents, etc.

Nitrocellulose. VICTOR PLANCHON. Fr. 36,714, Jan. 18, 1929. Addn. to 643,454 (*C. A.* 23, 1504). The process of the prior case is extended to sheets of all cellulosic material similar to wood pulp.

Nitrocelluloses. VICTOR PLANCHON. Fr. 691,138, May 8, 1929. Nitrocelluloses are made supersol. in the usual solvents by submitting them to the action of a strongly alk. substance, such as NH_3, washing, decolorizing and drying

Nitrocellulose. MILTON O. SCHUR and BENJAMIN G. HOOS (to The Brown Co.). Can. 307,372, Jan. 6, 1931. Cellulose fiber is treated with an aq dispersion of nitrocellulose, is preferably dried, and is then nitrated.

Producing designs on celluloid. PAUL M. S. SCHLOCHOFF. Ger. 510,177, Aug. 7, 1929. A glass sheet is dull-etched over its whole surface by means of HF or a sand blast, and the dulled surface is then etched again in the desired design so that different etching tones are perceptible. The celluloid, etc., sheet is then moistened with a solvent and pressed on to the glass by means of a roller.

Pyroxylin compositions. HAMILTON BRADSHAW (to Canadian Industries, Ltd.). Can. 307,396, Jan. 6, 1931. A cellulose ester compn. contains tetrahydrofurfuryl alc., a resin, a solvent softener, and ester of butyl alc., an alc. and a hydrocarbon oil. The compns. are suitable for use as brushing lacquers or enamels.

Artificial masses. I. G. FARBENIND. A.-G. Fr. 689,170, Jan. 31, 1930. Dry masses which, by the addn. of solvents, form mastics, dressings, insulators, cements, foundation paints, etc., are made from cellulose derivs. and binding agents such as resins or oils with or without fillers. Examples are given of the use of nitrocellulose and ethylcellulose.

Viscose. LOUIS C. P. JARDIN. Fr. 36,888, Feb. 9, 1929. Addn. to 641,866 (*C. A.* 23, 1268). An app. is described for obtaining alkali cellulose in the compressed and the noncompressed state for the manuf. of viscose. Cf. *C. A.* 24, 1980.

Viscose. STECKBORN KUNSTSEIDE A.-G. Swiss 140,972, Nov. 16, 1928. Mat fibers, films, etc., are produced from viscose contg. finely divided insol. particles. The particles are introduced by adding org. substances which are sol. in the viscose at first (*e. g.*, esters, leuco compds., etc.) but which are pptd. by the action of substances such as alkali or O in the viscose.

Apparatus for withdrawing gases evolved from viscose spinning baths. CARL HAMEL A.-G. Ger. 512,320, Mar. 20, 1928.

Device for spinning viscose solution. KALLE & CO. A.-G. (Julius Voss, inventor).

Ger. 510,946, Oct. 14, 1928. The drawing-out device is arranged to be set at a variable distance from the nozzle.

Artificial silk. BRITISH CELANESE, LTD., W. I. TAYLOR and R. P. ROBERTS. Brit. 334,195, March 28, 1929. Products of relatively reduced luster are obtained directly by the dry spinning method by adjusting the temp. of the spinning soln. so that it may be about 10–20° below that of the evaporative medium and below the minimum temp. required to produce highly lustrous products. The process is applicable to solns. of various cellulose esters and ethers, and numerous details and modifications of procedure are given. Brit. 334,198 relates to a similar process in which water or other diluent of higher b. p. than the solvent is added to the spinning soln. Cf. *C. A.* **24**, 5169.

Artificial silk. ALEXANDER WACKER GES. FÜR ELEKTROCHEMISCHE IND. G. M. B. H. Fr. 688,989, Jan. 28, 1930. Fine threads of artificial silk are made in the dry spinning process, by charging the thread before it is completely solidified with a swelling agent and afterward submitting it to a known drawing process.

Artificial silk. I. G. FARBENIND. A.-G. Fr. 689,121, Jan. 30, 1930. In making artificial silk by the wet method the threads from the spinning nozzles are caused to pass over a heated roller, etc., before reaching the winding cylinder. The roller may be sprinkled to prevent crystn. thereon of salts from the coagulating bath.

Artificial silk. NOVASETA A.-G. ARBON. Swiss 141,268, Oct. 8, 1928. A pptg. bath for artificial silk consists of meteoric water to which a small quantity of alkali hydroxide and hydrosulfite has been added to render the gases harmless.

Artificial silk. HENRY DREYFUS. Fr. 36,751, Mar. 23, 1929. Addn. to 531,816. Filaments or threads of artificial silk are made by extruding downward solns. of cellulose derivs. in the form of filaments received into a spinning chamber and passing for 3–6 m. or more through an evaporative medium and winding the filaments outside the chamber.

Artificial silk, etc. HENRY DREYFUS. Fr. 689,135, Jan. 30, 1930. Solvents used in the manuf. of artificial threads or filaments are recovered by heating the thread etc., and submitting them to a vacuum. A small quantity of air or other gas may be brought into contact with the threads during the treatment. Cf. *C. A.* **24**, 3360.

Artificial silk and similar products. BRITISH CELANESE, LTD., W. I. TAYLOR, R. P. ROBERTS and L. W. GREGORY. Brit. 334,563, March 28, 1929. Opaque, relatively insol. metallic compds. are formed in filaments, threads, etc., formed at least in part of cellulose acetate or other cellulose esters or ethers by spinning their solns., by the interaction of reagents, one of which is introduced into the spinning soln. while the other is applied to the materials during or after their formation. Numerous details and examples are given, among which is the production of $BaSO_4$, Pb sulfate or Ba phosphate, use of dyes with fixing agents comprising metal salts, etc.

Artificial threads. LÉON LILIENFELD. Fr. 37,021, June 10, 1929. Addn. to 666,178 (*C. A.* **24**, 1509). The extensibility of threads produced from viscose is increased by treating the dry, wet or damp threads with a caustic alkali soln. contg. 2–5% of alkali hydroxide (calculated as NaOH).

Artificial threads, etc. HENRY DREYFUS. Fr. 688,625, Jan. 21, 1930. Filaments, threads, etc., are made from solns. of cellulose acetate or other org. derivs. of cellulose in which a proportion of a wetting agent such as Turkey-red oil has been incorporated or the wetting agent is contained in the spinning bath.

Artificial threads, bands, etc. GLANZSTOFF COURTAULDS, G. M. B. H. Fr. 689,377, Feb. 3, 1930. Spinning solns. capable of being drawn out for the production of threads, bands, etc., are made by adding to viscose, sulfonated fatty oils such as Turkey-red oil, or their derivs., 0.3–2%. Before or after the addn. of sulfonated oils, insol. oil may be added to the viscose.

Artificial threads, ribbons, etc. HENRY DREYFUS. Fr. 690,432, Feb. 22, 1930. In making threads, ribbons, etc., by extruding solns. of cellulose esters or ethers into an evapg. agent, a relatively low luster is obtained by keeping the spinning soln. at about 10–20° below the min. required for the manuf. of products of normal luster.

An apparatus for washing cakes of artificial silk from the spinning pots. I. G. FARBENIND. A.-G. Fr. 688,806, Jan. 24, 1930.

Artificial silk spinning device. CARL HAMEL SPINN- & ZWIRNEREIMASCHINEN A.-G. Swiss 140,970, April 27, 1929.

Spinning nozzles for artificial silk. CAMILLE DREYFUS. Fr. 691,297, Mar. 6, 1930.

Spinning pot for artificial silk. WILHELM NIESSEN. Ger. 512,265, Dec. 9, 1928.

Spinning tubes for artificial silk. VEREINIGTE GLANZSTOFF-FABRIKEN A.-G. Fr. 690,214, Feb. 19, 1930.

Multiple draw plate for artificial silk manufacture. HENRI COLOMB. U. S. 1,788,660, Jan. 13.

Apparatus for artificial silk-thread manufacture. WM. H. FURNESS (to Cellocilk Co.). U. S. 1,788,484, Jan. 13. Structural features.

Treating wood, etc. KARL G. BERGSTRÖM and ARTHUR F. ZENNSTRÖM. Fr. 689,560, Feb. 7, 1930. Wood or other vegetable products are treated to obtain cellulose, with recovery of by-products, by exhaustion with a feeble alkali lye at ordinary temp. to recover AcOH, HCOOH and other acids. With a resinous wood a further treatment with heated stronger lye is given. The lignin obtained is used for the production of a pure C.

Sulfite lyes. PIERRE A. BARBOU (Pierre Weill, inventor). Fr. 36,977, Mar. 16, 1929. Addn. to 628,775. In the recovery of SO_2 and Na_2O from sulfite lyes the treatment with lime is followed by a treatment with CO_2 to transform the NaOH into Na_2CO_3 which will react to form $CaCO_3$ and $NaHSO_3$.

Organic materials from sulfite lyes. SOC. BARBOU ET CIE (Pierre Weill, inventor). Fr. 36,975, Mar. 15, 1929. Addn. to 642,270. In recovering org. materials contained in lyes from the treatment of vegetable materials with Na_2SO_3, $NaHSO_4$ is used instead of H_2SO_4 in the process of the prior case.

Cellulose pulp from lignocellulose material. ROBERT B. WOLF, RAYMOND P. HILL and RAYMOND S. HATCH. U. S. 1,788,555, Jan. 13. Material such as wood is treated with a non-aq. liquid contg. SO_2, *e. g.*, anhyd. liquid SO_2.

Bleaching paper pulp. WILHELM HIRSCHKIND (to the Great Western Electro-Chemical Co.). Can. 307,440, Jan. 6, 1931. Wood pulp is treated with $Na_2S_2O_4$ in the presence of moisture as a final bleaching step prior to the making of paper.

Apparatus for washing and pressing paper-making pulp. OTTO MANTIUS. U. S. 1,788,840, Jan. 13. Structural features.

Clarifying device for the waste waters of the cellulose and paper industry. FRITZ ARLDTER. Ger. 512,323, Feb. 29, 1924.

Paper. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 691,394, Feb. 27, 1930. Satd. higher fatty acids in the form of a salt having an I no. below 40, and preferably below 5, are added to paper pulp as sizing agents. Suitable acids are palmitic and stearic acids. Cf. *C. A.* **25**, 416.

Paper. I. G. FARBENIND. A.-G. (Kuno Franz and Carl Dankert, inventors). Ger. 510,855, July 2, 1929. Paper, etc., is treated on the side to be subsequently glazed, with a soln. of starch to which alkylcellulose has been added.

Paper and paper board. LEVIS M. BOOTH. U. S. 1,788,790, Jan. 13. In the manuf. of paper or paper board, a chlorinated material such as chlorinated lime is added to the stock and the inorg. residue is allowed to remain in the product.

Paper-making apparatus. PAPETERIES NAVARRE. Brit. 334,766, Oct. 31, 1928. Structural features.

Cylinder-mold screen for paper-making apparatus. JOHN S. LITTLE (to Western Elec. Co.). U. S. 1,788,531, Jan. 13. In applying celluloid strips to a cylinder mold screen, the strips are moistened with a solvent and joined with the screen by pressure.

Suction roll for paper machine. WM. H. MILLSPAUGH. Ger. 510,163, Jan. 31, 1929. This corresponds to Brit. 308,679 (*C. A.* **24**, 501).

Centrifugal separator for paper materials, cellulose, etc. PAUL ERKENS. Ger. 510,980, April 27, 1927.

Centrifugal sifting drum for paper, cellulose, etc., manufacture. SEIDL & MAYER and FIRMA FRITZ KIENZLE. Ger. 512,461, May 14, 1927.

Moistening device for traveling materials, such as paper. GUSTAV SCHLICK. Ger. 510,274, June 2, 1929.

Moistening device for traveling materials, such as paper. GUSTAV SCHLICK. Ger. 511,699, Mar. 30, 1930. Addn. to 510,274 (preceding abstr.).

Sizing paper. YA. G. KHINCHIN and B. YA. KUKIS. Russ. 38,274, Jan. 7, 1929. An aq. soln. of NaOH or Na_2CO_3 (0.5–1% of the wt. of the fiber) is added to the pulp simultaneously with, or before, the incorporation of a soln. of rosin glue.

Device for pulverizing waste paper. JAGENBERG-WERKE A.-G. Ger. 510,979, Aug. 17, 1928.

Removing printer's ink, etc., from paper. N. A. KUZIN. Russ. 52,792, Aug. 12, 1929. The paper is placed in a bath with a weak aq. soln. of NaCl which is then electrolyzed.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Consumption of explosives in November, 1930. W. W. ADAMS AND L. S. GERRY. Bur. Mines, *Rept. of Investigations* 3075, 9 pp.(1931).—Domestic sales of explosives manufd. in the U. S. in Nov. were 9,147,500 lb. of black blasting powder, 4,279,000 lb. of permissible explosives and 21,258,000 lb. of high explosives other than permissibles.

ALDEN H. EMERY

Stabilization of smokeless powder. ERMENEGILDO ACCOSSATO. *Rivista chim. sci ind.* 1, 273–9, 307–12(1930).—A review.

E. M. SYMMES

Black powder. K. A. HOFMANN. *Sitzb. preuss. Akad. Wiss.* 1930, No. 25 7, 432–6.—It has been shown previously (*C. A.* 24, 966) that the usual content of S in black powder influences its effectiveness considerably and that the velocity of combustion is favored autocatalytically. The reaction $2KNO_3 + S = K_2SO_4 + 2NO$ makes more readily available the combined O. In the second, or reduction, process, K_2SO_4 affords with excess C a further gas development, $4K_2SO_4 + 7C = 2K_2CO_3 + 2K_2S + 5CO_2$, and with excess S still more, $4K_2CO_3 + 7S = K_2SO_4 + 3K_2S_2 + 4CO_2$. A part of the S is regenerated, and re-enters the reaction. S-free powders burn more slowly, but involve the reactions $CO_2 + 2KNO_3 = K_2CO_3 + 2NO + 1.5\,O_2$ and $CO + 2KNO_3 = K_2CO_3 + 2NO + O_2$. Powder contg. S ignites at 290–300°, S-free powder at 320°, and S-KNO_3 mixts. at 430–70°. Exact thermal analyses show that S and black powder charcoal contg. gases produce, at 150°, H_2S and other sulfides, which attack vigorously KNO_3 at 285–90°, forming K_2SO_4. This rise in temp. melts KNO_3 and only molten KNO_3 can react with molten S and charcoal. S-free powder produces more CO. A powder contg. KNO_3 75 and red charcoal 25 gives a corrected gas vol. of 273 cc. contg. CO_2 8.3, CO 18.9, H_2 5.5, while a powder contg. KNO_3 71, S 11.2, red charcoal 17.8 gives 240 cc. of gas contg CO_2 23.5, CO 5.8, H_2 0.0, H_2S 3.5. The presence of S avoids formation of poisonous KCN dust.

E. M. SYMMES

The reconstruction of H_2SO_4 and HNO_3 mixtures (ALBERTO) 18.

Explosives. PAUL R. DE WILDE. Fr. 689,265, Feb. 3, 1930. See Swiss 130,658 (*C. A.* 24, 4397).

Smokeless powder. SERENO G. NORTON (to Hercules Powder Co.). U. S 1,788,438, Jan. 13. An abietate such as ethyl, phenyl or benzyl abietate (suitably in the proportion of about 5–10% of the total weight of the powder) is used with nitrocellulose and nitroglycerin, for improving the safety of manuf. and lessening burning temp and muzzle flash, etc.

Storing explosive gases. L'OXYHYDRIQUE INTERNATIONALE. Fr. 689,399, Feb. 4, 1930. Gases such as C_2H_2 dissolved in a solvent such as acetone are stored in the presence of a porous mass composed of large grains having a max. diam. of 1.5 mm. and small grains having a min. diam. of 0.5 mm, the ratio between the extreme dimensions having a max. of 2.

Indicator for explosive gas mixtures. I. F. MUKHARTOV. Russ. 51,129, July 13, 1929. An elec. testing device is specified.

Percussion bomb for rifles or bomb-firing appliances. RAIMONDO BOSSONE. U.S 1,788,856, Jan. 13. Structural features.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

A new group of anthraquinone vat colors containing the CONH linkage. R. N. LULEK. *Ind. Eng. Chem.* 23, 96–8(1931).—Dyes were prepd. by substituting anthronecarboxylic acid chloride derivs. in the NH_2 group of aminoanthraquinones. 1,9-Anthraisothiazole-2-carboxylic acid chloride was condensed with various substituted aminoanthraquinones. In general, this group brightens the shade similarly to the benzoyl group, and gives greater tinctorial value than the latter. The colors are cold-dyeing. Substitution of both NH_2 groups in diaminoanthraquinones gives dyes inferior in strength and other properties. The anthraisoselenazole-2-carbonyl group gives about the same tinctorial value as the corresponding thiazole compds., but deepens the shade,

having a stronger auxochromic effect. The anthraisothiophene-2-carbonyl group deepens the color more than the corresponding thiazole group, but decreases the tinctorial value. The deeper color is attributed to the fact that the C=C linkage in the thiophene ring is a stronger chromophore than the C=N in the thiazole ring. In all these products, Cl in the 6 position has greater tinctorial value than α-Cl, and —CONH in the β position gives greater tinctorial value and deeper shades than in 4 or 5.

I. H. ODELL

Technological factors of dyestuff production in Italy. Anthraquinone derivatives. VITTORIO MOLINARI. *Atti III congresso naz. chim. pura applicata* 1930, 499–508.—The attempt is made to produce vat dye in Italy. Difficulties encountered in the prepn. of anthraquinone derivs. of the indanthrene series are mentioned. However, it is believed that they can be overcome in time. E. GEBAUER-FUELNEGG

Perylene dyes. E. VECCHIONI AND G. MATSCHER. *Atti III congresso naz. chim. pura applicata* 1930, 569–72.—The experiences with the synthesis of perylene and its derivs. are reported. 3,10-Perylenequinone is obtained by direct oxidation of the perylene with chromic acid. The halogen derivs. are prepd. by bromination and chlorination in nitrobenzene suspension. The dyes obtained are extremely fast. The transformation of perylene in 3,9-benzoylperylene is as easy as the ring closure to isoviolanthrone. The latter and its halogen derivs. are of unusual quality and purity and compare favorably with the resp. indanthrene prepns. When nitroisoviolanthrone is oxidized with hypochlorite on the fiber a valuable gray or, in higher concns., Indanthrene Black B. is obtained. The yields are very satisfactory. Higher chlorinated products are easily prepd. and of interest as fast blacks for wool. Work on the perylene nitriles and carboxylic acids will be reported later. E. GEBAUER-FUELNEGG

New procedure for the preparation of chromium acetate. O. METZGER, M. GRANDJEAN AND M. ZURCHER. *Bull. Soc. Ind. Mulhouse* 96, 632–4(1930) (Sealed communication of 1913).—$Cr(OAc)_3$ *for mordanting* may be prepd. by dissolving 1 mol. of $Na_2Cr_2O_7$ and 1 mol. NaOAc in 5 mols. of 30% HOAc, then adding slowly 3 mols. $NaHSO_3$. The violet form of $Cr(OAc)_3$ is pptd. at the end of the reaction, while some remains in soln as the green form. If only 3 mols. HOAc are used, the product is $Cr(OAc)_3$.

I. O. ODELL

Dyeing **and finishing celanese fabrics.** HERBERT PLATT. *Proc. Am. Assoc. Textile Chem. Colorists* 1930, 15–21; *Am. Dyestuff Reptr.* 19, 19–25; *Dyer, Calico Printer* 63, 225–9, 231(1930). A. K. JOHNSON

Theory **of the dyeing of cellulose acetate silk.** E. CLAYTON. *J. Soc. Dyers Colorists* 46, 367–8(1930).—Certain data are grouped to advance a theory that cellulose silk is dyed by forming a solid soln. of the dye in the fiber through intimate contact produced in a highly dispersed bath. ROBERT HOUGHTON

The **importance of azo-dye-sulfites in connection with bleached and dyed wool.** A. J. HALL. *Am. Dyestuff Reptr.* 19, 725–8, 753–4(1930).—An account is given of some new and interesting developments regarding the reducing activity of Na bisulfite

MILTON HARRIS

The dyeing **of rayon mixture fabrics.** E. ROBERTSON. *Rayon Record* 4, 1149–51 (1930). A. K. JOHNSON

Construction **of celanese fabrics as related to dyeing and finishing methods.** HARRY PRICE. *Proc. Am. Assoc. Textile Chem. Colorists* 1931, 17–21; *Am Dyestuff Reptr.* 20, 19–23(1931).—If natural luster of fiber is to be preserved, temps. in wet processing should not exceed 180°F. The use of strong alkalies should be avoided. Satins, twills, taffetas and failes are dyed in the jig. Flat or warp knit fabrics are dyed on reels. Voiles and ninons may be dyed in open tanks. Celanese velvets may be dyed in the Star dyeing machine. Yarn may be either dyed by hand with the two stick method or in the standard dyeing machine. MILTON HARRIS

Dyeing **silk hosiery.** NOEL D. WHITE. *Am. Dyestuff Reptr.* 19, 741–4(1930).—In boiling off hosiery properly, about 20% of soap based on the amt. of silk is necessary. The goods should be washed in a hot water bath at 160°F. for 15 min. and then given a second rinse at 120°F. After boil-off and wash, the dyestuff is applied and the required amt. of Glauber salt entered. When the desired color is obtained, the goods are washed and finished. MILTON HARRIS

Factors involved in single bath, degumming and dyeing of silk hosiery. L. J. MCGINTY AND F. L. LA QUE. *Proc. Am. Assoc. Textile Chem. Colorists* 1931, 6–13; *Am Dyestuff Reptr.* 20, 8–15(1931).—No reduction will take place in the absence of sericin. Reduction may be prevented or controlled by aerating the soln. The use of degumming solns. having a p_H lower than the crit. value of 9.4 would eliminate the reduction of the dye. Since no reduction occurs at temps. below 203°F., it would

seem advisable to conduct the dyeing operations at as low a temp. as possible. MILTON HARRIS

Utility of the Hussong dyeing machine. J. HARRY THOMPSON. *Am. Dyestuff Reptr.* **19**, 746–7(1930).—This machine is used for dyeing raw stocks of cotton, wool, worsted, jute, hemp and flax yarns, also for ribbon and hosiery. MILTON HARRIS

The treatment of water for bleaching and dyeing. C. D. BLACKWELDER. *Am. Dyestuff Reptr.* **20**, 29–31(1931); cf. *C. A.* **25**, 597.—A discussion of difficulties encountered in bleaching and dyeing operations when unsuitable water is used. M. H.

Determination of the action of light upon dyes. PAUL KRAIS. *Am. Dyestuff Reptr.* **20**, 31(1931).—See *C. A.* **24**, 5162. MILTON HARRIS

Some notes on peroxide bleaching. H. G. SMOLENS. *Proc. Am. Assoc. Textile Chem. Colorists* **1931**, 2–4; *Am. Dyestuff Reptr.* **20**, 4–6(1931); cf. *C. A.* **24**, 5505.—Wool stock should be well scoured before bleaching. Wool piece goods are usually fulled after scouring, then washed, peroxide bleached by being run on an overhead reel through a bleaching soln. in a tub. Silk is bleached mostly in the form of piece goods, may be bleached on jigs, by immersion in stationary liquors in tubs, by padding and shelling and in continuous machines. Cotton stock is lightly peroxide bleached, usually in pressure machines as a prepn. for dyeing with vat colors. Cotton yarns are peroxide bleached in skeins, warps or packages. Cotton knit goods are handled in a manner similar to that of the yarns. The best bleaching of cotton piece goods is to prep. as for chemic bleach. MILTON HARRIS

The examination of selected combed tops with observations on continental measurements. C. G. WINSON. *J. Textile Inst.* **21**, 524–45T(1930).—The purpose of this study was to prep. a basis for an international scale of standards for combed tops with reference to the attribute of fineness. A complete range of tops collected by the Bradford Chamber of Commerce, the British Wool Federation and the U. S. A. Government were examd. and the mean cross-sectional area of the fiber was taken as the measurement of fineness. Measurements were also carried out on the British tops in which the results were expressed in terms of the wt. per unit length (10 m.) at 18¼% regain Fair agreement between the 2 methods was obtained except for the lowest qualities for which the latter method was found to be inadequate. RUBY K. WORNER

Staple fiber: Its production and use. M. HALAMA. *Rayon Record* **4**, 1183–9 (1930). - A description is given of the essential features for viscose staple fiber differing from making of ordinary long-filament viscose rayon, and modifications to give staple fiber of dull luster and fine filaments. A. K. JOHNSON

The production of staple fiber yarns: Spinning on the cotton system. H. SPIBEY *Rayon Record* **4**, 1191–5(1930).—The phys. characteristics of staple fiber and cotton are compared. Necessary modifications to cotton machinery are considered and various spinning processes are described. A. K. JOHNSON

Machine for testing the strength and elongation of a single fiber. TAMOTSU AOKI AND KATSUMOTO ATSUKI. *J. Soc. Chem. Ind. Japan* **33**, Suppl. binding, 383–5(1930). A testing machine for the measurement of the tensile strength and elongation of a single textile or paper fiber was designed and constructed so as to record the behavior of the fiber stretched by an increasing tension, photographically, in a manner giving a stress-strain curve. The position of the clamps holding the fiber was recorded on a film placed on a revolving drum as tension was applied to the fiber. The load may be calcd from the calibration curve of the spring used to stretch the fiber. From the photograph the load and elongation may be obtained for any point up to the breakdown. A. S. S.

Porosity: A primary property in textiles. I. The milling of wool fabrics. J. SCHOFIELD *J. Soc. Dyers Colourists* **46**, 368–72(1930).—The process of milling or felting in wool fabrics is essentially a diminution in the porosity. The limiting value is detd. by the min. of porosity along with the loss by surface attrition. The general properties of the fabric vary exponentially with the time of milling. **II. The thickness of cloths.** *Ibid* 372–5.—The detn. of cloth thickness is described. M. H.

The elastic properties of yarns, with special reference to tire cords. H. P. GURNEY AND E. H. DAVIS. *J. Textile Inst.* **21**, 463–80T(1930).—The nature of the elasticity of tire cord, its origin, its technical interest to tire designers and possible methods of measuring its value are considered; also the degree to which different possible measures of elasticity are intercorrelated. RUBY K. WORNER

The foundations of yarn-strength and yarn-extension. III. The clinging power of cotton. HARIRAO NAVKAL AND A. J. TURNER. *J. Textile Inst.* **21**, 511–23T(1930); cf. *Ibid* **19**, 286–314T; also *C. A.* **23**, 1753.—Adderley's method for detg. clinging power was modified so that 10 cotton fibers instead of 1 were pulled between pads made from parallelized fibers of the same cotton and subjected to a known pressure.

The force required to pull the 10 fibers through the pads under a known pressure is called the clinging power. According to the modified method, a greater force is required and can be measured more accurately. The results obtained with it are much more consistent than those with the previous method. Tests were carried out on some standard Indian cottons. RUBY K. WORNER

The moisture relations of cotton. VII. A study of hysteresis. ALEXANDER R. URQUHART AND NORMAN ECKERSALL. *J. Textile Inst.* **21**, 499–510T(1930); cf. *C. A.* **21**, 2069; **23**, 5380.—It is shown that the absorption and desorption curves for cotton form the boundaries of an equil. area, any point on which is capable of representing the amt. of water present in cotton under appropriate conditions of humidity and prehistory. Consequently in textile testing, fixing the temp. and relative humidity at const. values may not be sufficient to ensure comparable conditions, and addnl. precautions may be necessary if there are large differences of prehistory. The description curve above 80% relative humidity is indefinite in that above this value the amt. of H_2O retained is greater the greater the original excess above the satn. value. A definite curve can, however, be obtained when H_2O is removed from cotton contg. at least 40% H_2O. Cotton taken direct from the boll, or while still wet after kier-boiling or mercerizing, has an exceptionally high adsorptive capacity. Suggestions regarding the practical application of this property in technical processes are given. Data are given on the adsorption and desorption of H_2O by Sakel cotton, raw and soda-boiled at 25°; and by raw Webber and Acala cottons, and by soda-boiled and mercerized Sakel cotton at 20°. RUBY K. WORNER

Crimp in wool as a periodic function of time. MABEL H. NORRIS AND P. J. J. VAN RENSBURG. *J. Textile Inst.* **21**, 481–98T(1930).—In samples of Merino wool of widely different qualities and from various sources and in 2 samples of New Zealand Romney wool, the no. of crimps per fiber, in each lock, was found to be entirely independent of the fiber length, and to remain approx. const. for fibers of all lengths, except the very shortest. Conclusion: Crimp formation is a periodic function of time and is independent of the rate of growth of the fiber. RUBY K. WORNER

Some experiments in the soaking of silk. HARVEY A. NEVILLE AND THEODORE H. MARSHALL. *Ind. Eng. Chem.* **23**, 58–62(1931).—By means of dilatometers, measurements were made of the hydration or adsorption of water by silk during the process of soaking in oil-in-water emulsions to soften the fiber. In pure water there is first a contraction due to hydration, followed by an expansion attributed to bacterial action. Hydration decreases with increasing p_H and increasing temp., but the time required to reach equil. is greater at lower temp. In general, those conditions causing max. hydration cause min. increase in weight of silk because of adsorption of oil, as detd. by the boil-off method. The hydration in dye solns. is greater than that in pure water. In emulsions made with soap, the proportion of soap affects the degree of dispersion, stability, and action of the emulsion, as shown by photomicrographs. Increasing concn. of soap causes a decrease in hydration but an increase in the gain of weight. Emulsions of sulfonated oil give lower values of hydration and gain in weight than do soap emulsions. The use of triethanolamine as oleate alone or in combination with sulfonated oil results in improved dispersion and penetrating qualities, so that the desired gain in weight can be obtained in less time and with a lower concn. of oil.
I. H. ODELL

Strained viscose threads. Observations on previous tests and a new improved test. A. J. HALL. *Rayon Record* **4**, 1347–9(1930); cf. *C. A.* **25**, 203.—Strained viscose rayon and oxycellulose reduce $Fe_2(SO_4)_3$ to, and absorb, $FeSO_4$. $FeSO_4$ produces blue with Na ferricyanide. Glycerol allows addn. of caustic soda without pptn. The reagent has the following compn. in 100 cc. total vol.: 20% $Fe_2(SO_4)_3$ 5 cc.; glycerol 10 cc.; 10% NaOH 0–40 cc. Mix glycerol and $Fe_2(SO_4)_3$ and warm to 50° for a few min. Add the caustic hot (any ppt. redissolves); it can be safely heated on a boiling water bath ½ hr., in testing. In use have the reagent hot, immerse the material to be tested for a few min., rinse well in water, immerse for several min. in a dil. soln. of K ferricyanide acidified with HCl or H_2SO_4. Blue color slowly develops in steamed viscose or with oxycellulose. A. K. JOHNSON

Recent developments in the finishing of rayon materials. A. J. HALL. *Textile Colorist* **52**, 809–13(1930); cf. *C. A.* **25**, 821.—A review of the recent developments in finishing rayon materials which affect the softness, creasability and luster of these materials. RUBY K. WORNER

The prevention of stains in knitwear. S. R. TROTMAN. *Textile Mercury* **83**, 487 (1930).—A brief discussion is given of stains due to residual fiber impurities, soap, metals, oil, molds, bacteria and chemicals. A. K. JOHNSON

Dyes. CHEMISCHE FABRIK VORM SANDOZ. Fr. 686,738, Dec. 16, 1929. Polysulfonic acids of 1-amino-4-arylaminoanthraquinone which contain 2 SO_3H groups distributed on the 2 benzene rings of the anthraquinone complex are prepd. by heating, in aq. soln., halogen derivs. of anthraquinone sulfonated in the 5-, 6-, 7-, or 8-position with a sulfite in the presence or absence of PhOH. Examples are given. The products dye animal fiber in an acid bath.

Dyes. I. G. FARBENIND. A.-G. (Walter Bruck, inventor). Ger. 512,235, June 15, 1928. See Brit. 322,209 (*C. A.* **24**, 2891).

Dyes. I. G. FARBENIND. A.-G. (Erwin Hoffa and Fritz Müller, inventors) Ger. 510,479, Dec. 14, 1926. Orange to scarlet dyes are prepd. by coupling cyanaryl diazo compds. with the customary components, in substance or on the fiber. Numerous examples are given. Cf. *C. A.* **24**, 3651.

Dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD., E. H. RODD and F. L. SHARP. Brit. 334,689, Aug. 19, 1929. Triarylmethane dyes are made by condensing a diaryl dialkyldiaminodiphenylbenzohydroldisulfonic acid with *m*-2-xylidine and oxidizing (suitably with $Na_2Cr_2O_7$) in a single operation.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 334,706, Nov. 29, 1928. Equimol. proportions of a cyclic NH_4 salt contg. a reactive methyl group in α-position or the methylene base thereof and a compd. of the general formula $H—C\langle^{X}_{NH}$, in which X represents a univalent substituent such as NH_2, Cl, O-alkyl or O-acidyl, or a salt thereof, are condensed together to form an intermediate which, by further condensation with an equimol. proportion of the same or a different cyclic NH_4 salt having a reactive α-methyl group or the methylene base thereof, gives a polymethine dye. The cyclic NH_4 salts or their methylene bases may be condensed with imino ethers, imino esters, amidines and imino halides. Several examples are given.

Soluble dyes. THE TWITCHELL PROCESS CO. Fr. 690,505, Feb. 24, 1930. Dyes and intermediate products are made sol. by means of "mahogany" sulfonates, particularly true "mahogany" sulfonates. The method is very suitable for dyeing cellulose acetate.

Dyes and lakes. I. G. FARBENIND. A.-G. Brit. 334,754, Oct. 12, 1929. Monoazo dyes and lakes are made by coupling diazotized aminohydroquinone dialkyl ethers or their derivs. with 1-benzoylamino-8-naphthol-4,6-disulfonic acid or its derivs. substituted in the benzene nucleus, and, if desired, converting the products into lakes with alk. earth metal salts. The products dye wool fast violet and the lakes may be used for lithographic printing and in nitrocellulose lacquers. Examples are given.

Dye preparations. I. G. FARBENIND. A.-G. Fr. 689,488, Feb. 5, 1930. Dry prepns. suitable for the manuf. of dyes are prepd. by grinding alk. pastes of alkali salts of nitrosamines with neutral salts capable of absorbing water and dry components of azo dyes in the form of their free OH compds. or their alkali salts, capable of being coupled and having a substantive character but contg. no SO_3H or COOH groups. Examples are given.

Dye preparations. I. G. FARBENIND. A.-G. Fr. 690,393, Feb. 21, 1930. Stable prepns. sol. in water or alkalies, suitable for dyeing or printing, consist of dry mixts. of diazoamino compds. with naphthols, naphtholates or like coupling components.

The dyes are made by dissolving the mixt. in water or alkali when required. A long list of components and of the shades obtained is given.

Azo dyes. ERNST FELLMER (to General Aniline Works). U. S. 1,784,343, Dec. 9. Dyes dyeing silk reddish blue to black shades of good fastness to water and which can be discharged to a pure white with hyposulfite are obtained by combining the diazo compds. of *p*-diamines, *e. g.*, *p*-phenylenediamines, which are substituted in one of the two amino groups by an acyl radical, *e. g.*, formyl, acetyl, oxalyl, etc., and in the benzene or naphthalene nucleus, by, *e. g.*, halogen, alkyl and alkoxy groups with azo dye components, splitting off the acyl radical by saponification, diazotizing the resulting compd. and combining it with a hydroxynaphthalenesulfonic acid. The new dyes have most probably the general formula: RN:NX(Y)N:NR′, where X represents the residue of a *p*-diamine of the benzene or naphthalene series having not more than ten C atoms in nuclear linkage, Y represents a halogen, alkyl or alkoxy substituent, and R and R′ represent hydroxynaphthalenesulfonic acid azo-dye coupling components, the hydroxy groups of which stand in *o*-position to the azo groups. An example is given in which there are used as components 5-amino-4-chloro-2-oxyalylaminoanisole, 2 naphthol-6-sulfonic acid and 1-hydroxynaphthalene-5-sulfonic acid.

Azo dyes. RICHARD STÜSSER (to General Aniline Works). U. S. 1,785,845, Dec. 23. Azo dyes of the general formula 3,4-(HOOC)(RN:N)C_6H_3XC_6H_3(N:NR)(COOH)-4,3, where R represents the residue of any coupling component contg. in *o*-position to the azo group a substituent of the group comprising amino, arylamino, acylamino, hydroxyl and the desmotropic keto group; and X represents one of the groups azoxy and azo, may be obtained by subjecting 2 mol. proportions of dyes having the general formula 2,5-(RN:N)(NO_2)C_6H_3COOH, where R represents any coupling component contg. an auxochrome group, to careful reduction with alk. reduction means, *e. g.*, reduction by grape sugar and alk. agents, particularly NaOH soln. In this way there are obtained at first the azoxy compds. and then, by enhancing the reducing action, the corresponding azo compds. The azo compds. generally possess a deeper coloration than the corresponding azoxy compds. and the reduction process can be controlled by watching the coloration of the reaction mixt. In many cases, however, the reduction process cannot be controlled exactly and the reaction products in these cases represent mixts. of the azoxy compds. and the corresponding azo compds. The new dis- and poly-azo dyes obtained are generally sol. in water with a yellowish to bluish black coloration, sol. in concd. H_2SO_4 with a yellowish to bluish coloration, and dye cotton orange to blue to black shades which may be rendered fast to washing and to light by after treatment with heavy metal salts such as, *e. g.*, salts of Cu, Cr and Co. Several examples with details of procedure are given.

Azo dyes. JOHANN HUISMANN, HUGO SCHWEITZER and RICHARD STÜSSER (to General Aniline Works). U. S. 1,788,299, Jan. 6. Dyes producing good yellow dyeings on wool and forming yellow lakes of good properties, and which in general have the formula $CH_3COCH(N:NR)CONHR'$, where R represents an aromatic nucleus which is substituted by a nitro group in *o*-position to the azo group and which may be further substituted by any substituent with the exception of a sulfo group and R′ represents an aromatic nucleus which is substituted by a sulfo group and which may be further substituted, can be prepd., *e. g.*, by coupling a diazotized *o*-nitroarylamine with an acetoacetarylide and treating the azo dye thus obtained with a sulfonating agent in the usual manner, *e. g.*, sulfuric acid monohydrate or chlorosulfonic acid in an inorg. or org. solvent such as sulfuric acid monohydrate or chlorobenzene, thus converting the same into derivs. which are sulfonated in the aryl nucleus of the coupling components or alternatively by coupling a diazotized arylamine with an acetoacetarylide compd. which is substituted in the aryl residue by a sulfonic acid group. Several examples with details of procedure are given. U. S. 1,788,300 relates to production of dyes of the same general type and character, as, *e. g.*, by reacting with one mol. of 4-chloro-2-nitrobenzene-1-azoacetoacetic acid chloride dye upon one mol. of 2-anisidine-4-sulfonic acid, dissolved in pyridine at a temp. of about 30°.

Azo dyes. DANIEL ZINNER (to Newport Chemical Corp.). U. S. 1,789,279, Jan. 13. Dyes generally dyeing orange shades are formed by coupling tetrazotized 4,4′-diamino-2,2′-dimethyldiphenylmethane with one coupling component such as 1-(2′,5′-dichloro-4′-sulfo-)-phenyl-3-methyl-5-pyrazolone or 1-phenyl-3-methyl-5-pyrazolone and with a second coupling component such as 1-naphthol-4-sulfonic acid, β-naphthol, α-naphthol, 2-naphthol-6,8-(or 3,6-)disulfonic acid, 2-naphthol-6-sulfonic acid, 2-naphthol-7-sulfonic acid, 1-naphthol-5-sulfonic acid, 2-amino-5-naphthol-7-sulfonic acid, 2-benzoylamino-5-naphthol-7-sulfonic acid, 2-amino-8-naphthol-6-sulfonic acid or 1-naphthol-4-sulfonic acid.

Azo dyes. HENRY DREYFUS. Fr. 688,623, Jan. 21, 1930. New azo dyes are prepd. by coupling a diazo compd. of an *ar*-tetrahydronaphthylamine with a suitable coupling component, or coupling diazo compds. with an *ar*-tetrahydro-α-(or β)-naphthylamine or derivs. thereof. The dyes may be used as aq. dispersions for dyeing cellulose acetate. Examples are given. Fr. 688,624 describes the prepn. of new dyes by condensing an *ar*-tetrahydro-α(or β)-naphthylamine or a deriv. with an aromatic nitrated compd. contg. one or more labile halogen atoms. The compds. are *N*-nitroaryl-*ar*-tetrahydro-α(or β)-naphthylamines. Examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 691,216, Mar. 5, 1930. Cellulose esters or ethers are dyed by treating them with arylamides of 2,3-hydroxynaphthoic acid in an alk. bath contg. org. solvents, miscible with water, which constitute solvents or swelling agents for the esters or ethers and which are at the same time capable of dissolving the arylamides and their alkali salts (the solvent being added to the bath in amt. sufficient to swell but not dissolve the cellulose material) and developing by means of diazo compds. of aromatic bases. Examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 689,631, Feb. 8, 1930. Azo dyes insol. in water are prepd. by coupling 2,3-hydroxynaphthoylarylamines with diazo compds. of aromatic bases of the formula NH_2-R^1 . . . . . R^2-NHaryl, in which R^1 . . . . . R^2-represents a polynuclear or aromatic condensed system, the arylamino group being free from groups which render the products sol. in water, *e. g.*, SO_3H or COOH groups, and in which one of the N atoms is attached to R^1 and the other to R^2, and treating the dyes with a reducing or sapong. agent.

Azo dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 690,642, Feb. 25, 1930. See Brit. 329,056 (*C. A.* **24**, 5507). Fr. 690,643. See Brit. 329,961 (*C. A.* **24**, 6029).

Azo dyes. SOC. ANON. POUR L'IND. CHIM À BÂLE. Fr. 689,111, Jan. 30, 1930. New diazo dyes are prepd. by the union of the appropriate diazo compds. with the ethers of 1-amino-2-naphthol and their 6- or 7-sulfonic derivs., diazotization of the monoazo dyes thus obtained and coupling with the SO_3H derivs. of 2,5- or 2,8-aminonaphthols and their *N*-substitution products, in so far as they do not contain an external NH_2 group and, if necessary, sapon. of the products thus obtained. Thus, aniline 2-sulfonic acid is diazotized and coupled with 1-amino-2-methoxynaphthalene-6-sulfonic acid. The product is diazotized and coupled with 2-phenylamino-5-hydroxynaphthalene-7-sulfonic acid, giving a product which dyes artificial silk a bright blue. Other examples and a table of components which may be used and the shades obtained are given.

Azo dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 140,600 to 140,606, May 10, 1928. Addns. to 138,024 (*C. A.* **25**, 822). An azo dye contg. metal is prepd. by treating the chromed dye obtained from nitrated 1-diazo 2-hydroxynaphthalene-4-sulfonic acid, β-naphthol and $(HCOO)_3Cr$, with a Ni salt in the warm and in the presence of AcONa. Examples are given. The dye colors wool and silk black. The Ni may be replaced by Mn, Cu, Na or NH_4 and Cu

Soluble azo dyes. I. G. FARBENIND. A.-G. Brit. 334,529, May 1, 1929. Compns. for dyeing and printing material with azo dyes sol. in water or alkali are made by incorporating, in the dry state, a water-sol. diazoamino compd. prepd as described in Brit. 320,324 (*C. A.* **24**, 2612) or Brit. 324,041 (*C. A.* **24**, 3382) with a coupling component for producing azo dyes free from sulfonic and carboxylic groups such as a 2,3-hydroxynaphthoic acid arylide. Numerous examples are given.

Azo dyes and intermediates. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 690,311, Feb. 20, 1930. Monoazo and disazo dyes are prepd. by combining diazotized oxamic acid derivs. of 4,4'-diaminodiphenylmono- or tri-sulfide with coupling components. In the case of disazo dyes one mol. proportion of the diazo component may be replaced by one mol. proportion of another diazo component. The oxalyl group may be removed by hydrolysis and the resulting aminoazo, aminodisazo or diaminodisazo compds. may be diazotized or tetrazotized and coupled with components to obtain disazo, trisazo or tetrakisazo dyes. The oxamic acid derivs. are obtained by boiling the diamino compds. with an aq. soln of oxalic acid. Several examples are given.

Diazo dyes. I. G. FARBENIND. A.-G. Fr. 689,419, Feb. 4, 1930. Diazo dyes insol. in water are prepd. by combining in substance or on a support, particularly vegetable fiber, tetrazo compds. of diamino bases which are obtained by condensing aromatic amines contg. no SO_3H or COOH groups with ketones, with azo components which contain no solubilizing groups such as SO_3H or COOH. Thus, the product obtained by condensing 2 mols. of $PhNH_2$ with 1 mol. of acetone is tetrazotized and the product poured into an alk. soln. of β-naphthol, giving a yellowish red powder. Other examples and a table of components with the colors obtained are given.

Blue trisazo dyes. HENRY JORDAN (to E. I. du Pont de Nemours & Co.). U. S. 1,788,797, Jan. 13. Blue trisazo dyes for cotton, of good fastness to light, are formed by diazotizing a 1-amino-8-naphtholdisulfonic acid (such as the 3,6-disulfonic acid) having only one sulfo group in each nucleus, coupling the diazo compd. to α-naphthylamine or other amino compd. having a free *p*-position and not contg. a free OH, sulfo or second amino group, diazotizing the amino-azo compd., coupling it to 2-amino-5-naphthol-7-sulfonic acid, diazotizing the disazo dye and coupling it with a coupling component of the naphthalene series having at least one OH group such as 1,8-aminonaphthol-3,6-disulfonic acid. Cf. *C. A.* **24**, 2304.

Disazo dyes. ALFRED GRESSLY (to General Aniline Works). U. S. 1,787,676, Jan. 6. Dyes are obtained by combining an arylamide of 2,3-hydroxynaphthoic acid wherein the aryl may be substituted, with a diazotized aminoazo compd. of the general formula,

$$\left[R_1—N{=}N—R_2\right]\begin{matrix}—NH_2\\—SO_3H,\\—X\end{matrix}$$

where R_1 and R_2 are aryl residues which may be substituted by univalent groups and X is a sulfonic or a carboxylic acid group. The new dyes correspond to the general formula:

$$1,2,3=\left(\left[R_1—N—N—R_2\right]\begin{matrix}—N{=}N—\\—SO_3H\\—X\end{matrix}\right)(OH)(CONHR)C_{10}H_5,$$ where R, R_1, R_2 and X have the aforesaid meaning. They dye wool blue to bluish black shades of a good fastness to washing, hot-pressing and light. The dyeings may be after-chromed if the dyes applied contain the well-known groups suitable for this after-treatment. Among the starting materials which may be used are: 1-aminonaphthalene-4-sulfonic acid, 1-aminonaphthalene-7-sulfonic acid and 2-hydroxynaphthalene-3-carboxylic anilide; 1-aminonaphthalene-3,6-disulfonic acid, α-naphthylamine and 2-hydroxynaphthalene-3-carboxanilide; and *p*-aminosalicylic acid, 1-aminonaphthalene-7-sulfonic acid and 2-hydroxynaphthalene-3-carboxanilide.

Disazo and polyazo dyes. WINFRID HENTRICH, MAX HARDTMANN, RUDOLF KNOCHE and JOSEF HILGER (to General Aniline Works). U. S. 1,788,295, Jan. 6. Dyes of various colors are prepd. by reacting upon a heterocyclic compd. contg. 2 successively replaceable halogen atoms with 1 mol. proportion of an aminoazo compd. and one mol. proportion of an amino compd., the radical of which is capable of coupling with diazo compds. after condensation, and reacting upon these condensation products with a diazo compd. Among the starting materials which may be used are: 5-chlorouracilic acid chloride, trichloropurine, trichloropyrimidine, methyldichloropyrimidine, phenyldichloropyrimidine, dichlorobenzopyridazine, dichloroacetylguanamide, 2,4-dichloroquinazoline, 2-phenyl-(3′-carbonic acid chloride)-4-chloroquinazoline, 2,4,7-trichloroquinazoline, 2,4-dichloro-5,7-dibromoquinazoline, 1-phenyl-(4′-carboxylic acid chloride) 4-chlorophthalazine, 2-chloroquinoxaline-3-carboxylic acid chloride, 2,3-dichloroquinoxaline-6-carboxylic acid chloride, 2,4-dichlorocopazoline, 2,4-dichloro-10-monazine-1,3 diazine (cf. *Ber.* **34**, 1341 (1901)) and 2,4-dichloro-1,3-diazine-5,8 diazine. There may be employed for the introduction of aminoazo residues: the monoacylarylenediamines, phenylenediamine, the 3- or 4-nitroarylamines and the 3- or 4 arylenediaminesulfonic acids. The following are examples of amino compds., the radical of which is capable of coupling with a diazo compd after the condensation: amino hydroxy compds of the naphthalene series, such as aminonaphtholsulfonic acids, naphthalenediamines, such as 1,8-naphthalenediamine-4-sulfonic acid and substitution products thereof, and also aminoarylpyrazolones with an unoccupied 4-position in the pyrazolone ring. Numerous details with examples of procedure are given.

Vat dyes. I. G. FARBENIND. A.-G. Brit. 334,240, May 30, 1929. Vat dyes producing violet to blue shades on cotton are prepd. by condensing *Bz*-3,5-dichloro-4-chloranthraquinone-2,1(*N*)-acridone with amides of aromatic carboxylic or sulfonic acid and the products may be saponified if desired. Several examples with details of procedure are given.

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Koberle, inventors). Ger. 510,481, Dec. 9, 1928. Addn. to 457,493. Dyes contg. halogen are prepd. by treating *allo-ms*-naphthodianthrone or its derivs. with one or more halogens or halogenating agents while suspended or dissolved in an inorg. liquid, *e. g.*, H_2O, H_2SO_4 or oleum. When products contg. only one of the halogens are to be made, the solvent or diluent may be dispensed with. Catalysts may be present. The products may be

identical with those described in Ger. 468,988 (*C. A.* **23**, 3352) and 470,948 (*C. A.* **23**, 2042), but new products are also obtainable. Examples are given.

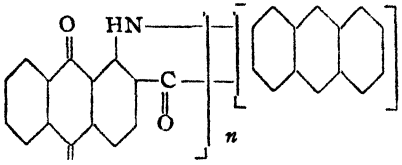
Vat dyes. I. G. FARBENIND. A.-G. (Rudolf M. Heidenreich, inventor). Ger. 510,482, Mar. 11, 1928. New products useful as vat dyes or intermediates are prepd. by converting amino- or halo-anthranthrones into the corresponding nitriles by the Sandmeyer reaction or by heating with CuCN. Examples are given describing the prepn. of *2,7-dicyanoanthanthrone* and a *monocyanoanthanthrone.*

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 510,600, July 8, 1929. Addn. to 499,169 (*C. A.* **24**, 4168). The method of Ger. 499,169 is carried out at a temp. above 50°. The products have a greater ratio of Br to Cl than those of the prior patent, and give different blue to violet shades on vegetable fibers. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 688,560, Jan. 20, 1930. Vat dyes contg. S are obtained by treating 2,5-diarylamino-3-mercapto-1,4-benzoquinones by oxidizing agents. Thus, 2,5-dianilino-3-mercapto-1,4-benzoquinone (by treating 3,6-dianilino-2-chloro-1,4-benzoquinone with Na_2S in an aq. alc. soln. and pptg. the product by dil. HCl) is boiled in $PhNO_2$. The product which seps. on cooling dyes wool in intense brown shades, and is 3-anilinophenothiazine. Other examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 689,172, Jan. 31, 1930. Blue vat dyes of great fastness are prepd. by mixing with *N*-dihydro-1,2,2′,1′-anthraquinoneazine or its substitution products such as its monochloro deriv., the dyes capable of being prepd. by treating *N*-dihydro-1,2,2′,1′-anthraquinoneazine, the Blue Indanthrene RS of commerce, with sulfonating agents having a controlled action, preferably in the presence of H_3BO_3 or according to the methods of the 4th and 5th patents of addn. to Fr. 670,562.

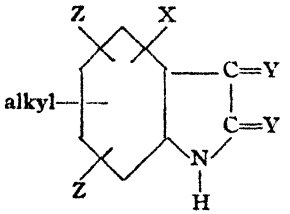
Vat dyes. I. G. FARBENIND. A.-G. Fr. 36,631, Oct. 29, 1928. Addn. to 651,152 (*C. A.* **23**, 3351). Vat dyes are prepd. by condensing N compds. of the dibenzanthrone or isodibenzanthrone series, which have at least one atom of substitutable H fixed to the N, with mono- or poly-nuclear heterocyclic compds., contg. fixed to the heterocyclic rings one or more neg. substituents, or with their derivs. or their homologs so that the neg. residues are in part or wholly replaced by the dibenzanthrone or isodibenzanthrone group. The products if they still contain neg. substituents may be condensed with other appropriate compds. Examples are given of the condensation of aminodibenzanthrone with cyanuric bromide and with 2,4,6-trichloro-1,3,5-triazine and of amino-isodibenzanthrone with 2,4-dichloroquinazoline.



Vat dyes. I. G. FARBENIND. A.-G. Fr. 36,782, Nov. 13, 1928. Addn. to 651,152 (*C. A.* **23**, 3351). Vat dyes are prepd. by treating, in the presence of solvents or diluents, nitro compds. of the dibenzanthrone or isodibenzanthrone series with a reducing agent insufficient to reduce all the NO_2 groups to NH_2 and condensing the mixts. which result from the reduction, preferably in the presence of solvents or diluents of high b. p., and if necessary with the addn. of catalysts or acid-fixing agents or both. The reduction may be carried out so that less than half the NO_2 groups are reduced, and one or more N compds. having at least one replaceable H fixed to the N are caused to react with the reduction mixt. during or after its condensation. Or, more than half the NO_2 groups are reduced and one or more aromatic compds. contg. one or more neg. substituents are caused to react on the reduction mixt. during or after its condensation. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 36,908, May 8, 1929, Addn. to 650,501 (*C. A.* **23**, 3353). The condensation products from halogenated anthanthrones and aminoanthraquinones and still contg. free NH_2 groups in the mol. are treated with acylating agents, or halogenated anthanthrones are condensed with aminoanthraquinones which contain acylamino groups as well as a free NH_2 group in the mol. The products have greater affinity for vegetable fiber and better dyeing qualities than the nonacyl compds. of the prior case. Examples are given.

Vat dyes and intermediates. I. G. FARBENIND. A.-G. Fr. 687,798, Jan. 7, 1930. Vat dyes or dye intermediates are obtained by heating to a high temp. 2-amino-3-cyanoanthraquinone or its derivs. or substitution products in indifferent solvents, preferably in the presence of Cu or Cu compds. Examples are given of the treatment of 2-amino-3-cyanoanthraquinone and its bromo deriv., prepd. by brominating 2-amino-3-cyanoanthraquinone in $PhNO_2$. Vat dyes are obtained in each case.

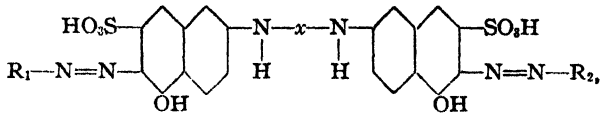


Brown vat dyes of the anthraquinone series. WERNER ZERWECK (to General Aniline Works). U. S. 1,785,801, Dec. 23. Brown dyes of good fastness to light are obtained by condensing amines of the anthracene series with 1-chloroanthraquinone-2-carboxylic acid. The process may be carried out by prepg. first the corresponding

anthryl-1-aminoanthraquinone-2-carboxylic acid and transforming it into the corresponding acridone, while splitting off water, or by transforming the anthryl-1-aminoanthraquinone-2-carboxylic acid into the chloride and converting the latter into the acridone, while splitting off HCl. But it is preferable to produce the acridone in a single operation by condensing aminoanthracenes with 1-chloroanthraquinone-2-carboxylic acid. The new dyes thus obtained correspond probably to the general formula

where *n* means the number 1 or 2 and the anthracene as well as the anthraquinone nuclei may contain further substituents. Several examples with details of procedure are given.

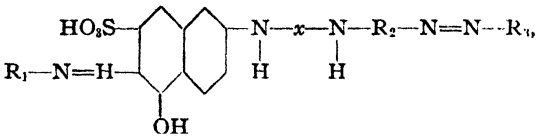
Indigoid vat dyes from dihaloalkylisatins. CARL KRAUSS (to General Aniline Works). U. S. 1,784,452, Dec. 9. Dyes of the general formula



where Z represents Cl or Br, X represents H or alkyl, one Y represents O, the other Y stands for the residue of a cyclic ketomethylene compd., are dark-colored powders, sol. in concd. H_2SO_4 with characteristic coloration and form with hyposulfite solns. usually yellow colored vats from which cotton is dyed fast shades ranging from a bright red to deep navy-blue shades. They may be prepd., for instance, by condensing dihaloalkylisatin or a dihaloalkylisatin compd., in which the α-C atom is substituted by a reactive substituent with a cyclic ketomethylene compd. Suitable reactive substituents are, for instance, halogen atoms, particularly Cl, S, arylamino groups, alkoxy groups, etc. Compds. of this type may be exemplified by 5-bromo-6-chloro-7-methylisatin α-chloride and 5,7-dichloro-6-methylisatin-α-anilide, and the cyclic ketomethylene compds comprise such aromatic compds. as contain a desmotropic oxy group as, for instance, 1-naphthol, 4-chloro-1-naphthol, anthrol, which supposedly react in their tautomeric ketomethylene forms, ketothionaphthenes, ketonaphthothiophenes, indoxyls, naphthindoxyls, etc.; 3-ketothionaphthene-2-carboxylic acids react in a similar manner, CO_2 being split off during the reaction and such carboxylic acids are, for purposes involved, considered equiv. to the ketothionaphthenes themselves.

Trimethylthionaphthene vat dyes. ERWIN HOFFA and HANS HEYNA (to General Aniline Works). U. S. 1,782,724, Nov. 25. 4,6,7,4',6',7'-Hexamethylthionindigo has good fastness to light, besides the other good tinctorial properties, and can be obtained by subjecting the 3,5,6-trimethylbenzenethioglycolic acid or a substitution product thereof contg. in 2-position the carboxy, carbonyl or cyano group to condensation according to one of the usual methods and oxidizing the hydroxythionaphthene thus produced so as to form the desired dye. Also the products, obtainable by condensing the new hydroxythionaphthene according to the usual methods, exhibit fastness properties similar to those of the dye obtainable by oxidizing the said hydroxythionaphthene. Details of preparation are given.

Leuco esters of vat dyes. I. G. FARBENIND. A.-G. Fr. 688,748, Jan. 23, 1930. Leuco esters of vat dyes are prepd. by treating the leuco derivs. with halides of sulfobenzoic acids, $HO_3CC_6H_4SO_2X$ (X = halogen). An example is given of the treatment of leucothioindigo with the chloride of sulfobenzoic acid in pyridine.



Dyes containing metals. HANS GUBLER, GUILLAUME DE MONTMOLLIN and JOSEPH SPIELER (to Soc. Chem. Ind. in Basle). U. S. 1,783,083, Nov. 25. Dyes producing orange, red, Bordeaux and brown shades fast to light on cotton, and on re-

generated cellulose products, comprise metals such as Cu, Cr or Mn in combination with azo dyes of the general formula

where x stands for an org. residue contg. C at least one atom, the —NH— groups being linked to such C atoms of said residue which are united by a double bond with a N, O or S atom, and where R_1 is the residue of a benzene nucleus characterized by the presence of a COOR group (R=H or alkyl) standing in *o*-position to the —N:N— group, and R_2 is the residue of a benzene nucleus characterized by the presence of a COOR or OR group (R=H or alkyl) standing in *o*-position to the —N=N— group Numerous examples and details of manuf. are given.

Dyes containing metals. Hans Gubler (to Soc. Chem. Ind. in Basle). U. S. 1,783,084, Nov. 25. Complex metal compds. such as those of Cu, Co, Ni, Al, V, Cr, Ti, Mn, Fe, Mo, Ce and U with azo dyes of the general formula

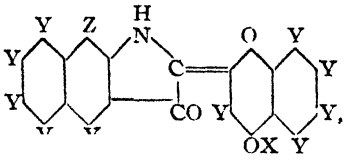
where x stands for an org residue contg. at least one C atom, the —NH— groups being linked to such C atoms of said residue which are united by a double bond with a N, O or S atom, and where R_1 is the residue of a benzene nucleus characterized by the presence of a COOR group (R=H or alkyl) standing in *o*-position to the —N=N— group, R_2 is an aryl nucleus, and R_3 an aryl nucleus which carries a carboxyl group and a OH group standing in *o*-position to each other, yield on the vegetable fiber, as well as on artificial fibers of the group of the regenerated cellulose, such as viscose or cuprammonium silk tints, particularly orange to brown, red, Bordeaux and brown, which are of good fastness to light. Various examples with details of procedure are given

Sulfur dyes. I. G. Farbenind. A.-G. (Friedrich Muth, inventor). Ger. 510,483, Sept. 16, 1927. See Brit. 297,123 (*C. A.* **23**, 2578).

Sulfur dyes. I. G. Farbenind. A.-G. (Erwin Kramer, Bernhard Bollweg and Ludwig Zeh, inventors). Ger. 510,484, Sept. 1, 1927. Red-brown dyes are prepd by heating β-binaphthol at 60–100° with halides of S, with or without S. Indifferent solvents may be present. Examples are given. Cf. *C. A.* **24**, 1989, 3654.

Sulfur dyes. I. G. Farbenind. A.-G. Fr. 36,984, May 28, 1929. Addn. to 653,785 (*C. A.* **23**, 3816). S dyes are prepd. by treating at higher temps. dinaphthylene dioxide with S halides with or without diluents. Examples are given using S_2Cl_2 in which temps. of 250–80° are used.

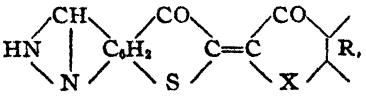
Green sulfur dyes. N. A. Zaitzev. Russ. 21,830, Dec. 16, 1927. Green sulfur dyes are prepd by fusing polysulfides, in the presence of Cu, with leucoindophenols from *p*-aminophenol and 1-arylnaphthylamine-8-sulfonic acids. The mixture, obtained after the reduction of indophenol by Na_2S in the leuco compd., to which a Cu salt has been added, is treated with NaCl and AcOH to ppt. the complex Cu indophenol compd. The ppt. so obtained is fused with Na polysulfide by the usual methods after the soln. has been sepd.



Sulfo derivatives of 1-aminonaphthalene-8-carboxylic acid. Richard Herz and Fritz Schulte (to General Aniline Works). U. S. 1,780,077, Oct. 28. By reacting under mild conditions (as with milk of lime at 200–250°) with an alk. agent upon a nuclear substitution product of 8-cyanonaphthalene-1-sulfonic acid contg. a further sulfonic group in the nucleus in a β-position (such as the Na salt of 8-cyanonaphthalene-1,6-disulfonic acid) there are produced compds. such as 8-amino-3-sulfo-1-naphthoic acid (I) or its 1,8-cyclic anhydride (II). I when dry is a colorless powder sol. in dil. soda soln., diazotizable and capable of combining with diazo compds; in the form of its anhydride it is a yellowish powder neither diazotizable nor capable of combining with diazo compds. These compds. may be used as *dye intermediates* and in the manuf. of *pharmaceutical compds.*

Sulfonated water-soluble dyes of the diaminobiphenyl series. Karl Thiess and Bernhard Deicke (to General Aniline Works). U. S. 1,780,048, Oct. 28. Diaminobi-

phenyls of the formula, $NH_2C_6H_4C_6H_4NH_2$, wherein the H atoms of the phenyl groups may be substituted or not, such as benzidine, dichlorobenzidine, diphenyline (2,4'-diaminobiphenyl), can be condensed in both amino groups with a compd. of the general formula, $(NO_2)(Hlg)R\text{-aryl-}SO_2OX$, wherein Hlg stands for an exchangeable halogen atom, R for a nitro group or H and X for H or a metal, and the yellow to brownish red condensation products thus obtained are sol. in water and dye animal fiber greenish yellow to brownish red tints. They are more homogeneous and faster to light and give purer shades than the similar dyes prepd. as described in German pat. 22,268 by sulfurizing the corresponding nitroamines. The condensation can be effected in water in an open vessel at a temp. of about 100° or in an autoclave at a temp. up to about 200° with the addn. of an acid-binding agent such as Na_2CO_3, NaOAc or the like and gives a very good to quant. yield. In some cases the reaction can be accelerated by the addn. of org. solvents as, for instance, alc., there may also be added a catalyst such as Cu powder. Numerous examples are given, one of which relates to the condensation of *o*-anisidine with 2 mol. proportions of K 1-chloro-2-nitrobenzene-4-sulfonate in the presence of water and Na_2CO_3 for 12 hrs. at a temp. of 120-30°.



Acid wool dyes. GEORG KRÄNZLEIN, FRITZ ROEMER and ERICH KRONHOLZ (to General Aniline Works). U. S. 1,780,976, Nov. 11. Dyes of good leveling power are obtained by causing a 1-amino-4-haloanthraquinone-2-sulfonic acid to react with *m*-aminomethylacetanilide or other suitable base of the general formula, $m\text{-}NH_2C_6H_4NXY$ wherein X stands for an alkyl or aralkyl group and Y stands for an aliphatic acyl residue, in the presence of Cu or a Cu compd. while heating. The new dyes correspond to the general formula: $1\text{-}NH_2\text{-}2\text{-}MO_3S\text{-}4\text{-}(m\text{-}XYNC_6H_4NH)C_6H(CO)_2C_6H_4$, wherein X stands for an alkyl or aralkyl group, Y for an aliphatic acyl residue and M for a metal or for H. They are generally of blue color. Cf. *C. A.* **24**, 2307, 2895.

Indigoid dyes. WILHELM BAUER, WILHELM NEELMEIER and THEODOR NOCKEN (to General Aniline Works). U. S. 1,782,706, Nov. 25. Indigoid dyes of the general formula:

where X stands for an alkyl residue, Y for H or any other substituent and Z represents a halogen atom, may be prepd. by causing a reactive α-deriv. of a 2,3-naphthisatin substituted in the 1-position by halogen to be acted upon by a monoalkyl ether of the 1,4 dihydroxynaphthalene or a deriv. thereof, which is not substituted in the *o*-position to the hydroxyl group. They are generally dark bluish green cryst. powders, sol. with difficulty in cold concd. H_2SO_4 mostly with a green coloration, dyeing the textile fiber from a reddish brown vat in fast green shades. Examples are given.

Indigoid dyes. I. G. FARBENIND. A.-G. Fr. 687,061, Dec. 20, 1929. New dyes of the indigoid series giving bluish gray to olive shades are prepd. by transforming a 6-aminoindazole or its substitution product into the corresponding *o*-mercaptan, treating this with $ClCH_2COOH$ to form the corresponding thioglycolic acid, then transforming this in the usual manner into a hydroxythionaphthene compd., and treating the hydroxypyrazolethionaphthene thus obtained with an oxidizing agent or condensing it with a compd. capable of forming indigoid dyes. The compds. probably correspond to the general formula

in which the CH group is para with respect to the CO group, the benzene and pyrazole rings may have substituents, R is an aromatic residue and X represents NH or S.

Indigoid dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 689,230, Feb. 1, 1930. New dyes are prepd. by condensing 4,5-dichloro-7-methyl-3-thionaphthenone, if necessary after its transformation into the corresponding thionaphthenequinonic derivs. (*e. g.*, by condensation with *p*-nitrosodimethylaniline), with the components usually employed for the prepn. of indigoid dyes. The fastness of the dyes may be improved by halogenation. The 4,5-dichloro-7-methyl-3-thionaphthenone may be conveniently

prepd. by treating chlorotoluidine (CH_3,NH_2,Cl = 1,2,4) with Ac_2O, chlorinating and sapong. to get 4,5-dichloro-*o*-toluidine, which, by diazotization, action of K xanthogenate, sapon. and condensation with $ClCH_2COOH$ is transformed to 3,4-dichloro-6-methyl-1-phenylthioglycolic acid. The latter is transformed to the thionaphthenone by the usual methods. Examples are given.

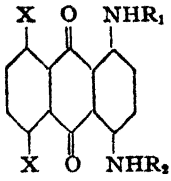
Triarylmethane dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 689,109, Jan. 30, 1930. Lakes of basic triarylmethane dyes and acid dyes of this series contg. basic groups are prepd. by treating the leuco compd. of such a dye with a soln. contg. a complex inorg. acid and an oxidizing agent. Several examples are given.

Mordant dyes. DURAND & HUGUENIN S. A. Fr. 690,539, Feb. 25, 1930. Mordant dyes are prepd. by submitting to an oxidation, preferably with $Ca(OCl)_2$, amino monoazo or amino polyazo dyes corresponding to the general formulas: $R'.N:N.R^n.NH_2$, $R'.N:N.R^2.N:N.R^3. \ldots N:N.R^n.NH_2$, in which R' is an aromatic ring contg. the necessary constituents for a mordant dye, *e. g.*, COOH and OH in the *o*-position, R^2, R^3, etc., signify intermediate rings joined by azo groups and which may contain substituents preferably SO_3H or COOH, and R^n is a terminal ring which can contain besides the NH_2 in *p*-position to the azo group, other substituents, preferably SO_3H or COOH. Examples are given.

Mordant dyes. I. G. FARBENIND. A.-G. (Werner Lange, inventor). Ger. 510,480, Feb. 12, 1927. Mordant dyes are prepd. by coupling 1 mol. of resorcinol or its nuclear substitution products with 2 mols. of a diazo compd. or compds. from one or more 4-amino-1-hydroxyaryl carboxylic acids. Examples are given. The products give brown shades when chrome-printed.

Mordants for dyes. CHEMISCHE FABRIK VORM. SANDOZ. Fr. 689,807, Feb. 12, 1930. See Brit. 325,388 (*C. A.* **24**, 4169).

Making basic dyes fast to light. I. G. FARBENIND. A.-G. Fr. 36,864, May 3, 1929. Addn. to 639,469 (*C. A.* **23**, 716). A dye of rhodamine B extra on a mordant of Sb and tannin is treated for ½ hr. at 50–60° with a soln. of 0.1–0.2 g. of the reduction compd. of Mo, W and P referred to in the prior case in 100 cc. of water and dried without rinsing, to increase its fastness to light.



***o*-Aminoaryl mercaptans.** RICHARD HERZ and MAX SCHUBERT (to General Aniline Works). U. S. 1,784,441, Dec. 9. 1-Methyl-2-amino-5-chlorobenzene 3-mercaptan, and, in general, *o*-aminoaryl mercaptans (intermediates for making thioindigo dyes) of the general formula 1,2-$(NH_2)(SH)$-aryl-Y-4, wherein Y means that the 4-position is either substituted or blocked are made by treating *o*-aminoaryl thiocyanates of the general formula 1,4-(NH_2)-Y-aryl-SCN-2, wherein Y has the aforesaid significance, obtainable, *e. g.*, by causing an inorg. thiocyanate and a halogen to act on a primary aromatic amine having the *p*-position to the amino group blocked in the presence of a solvent of a neutral character, with alk. saponifying agents, under exclusion of air, preferably in the presence of a reducing agent. Advantageously alk. agents having simultaneously a reducing effect as, for instance, an aq. or alc. soln. of alkali sulfides or polysulfides may be used. Several examples are given.

Halogenated anthraquinoneacridone. I. G. FARBENIND. A.-G. Fr. 688,789, Jan. 24, 1930. A halogenated anthraquinoneacridone is obtained by sepg. from the intermediate product produced by the action of Cl on 1-anilido-2-methylanthraquinone or on 1-*o*-toluidoanthraquinone in org. solvents, the component more sol. in the org. solvents, and eliminating Cl or HCl from this component, preferably in the presence of reducing agents or at a high temp. or both. Thus, Cl is passed into a soln. of 1-anilido-2-methylanthraquinone in $C_6H_3Cl_3$ at 170–180°, and the reaction mixt. allowed to cool and filtered. The filtrate is allowed to stand a few days and the product which separates is boiled with *o*-dichlorobenzene and phenol. HCl is evolved and the product dyes *cotton* in bluish red shades.

***o*-Aminoaryl mercaptans.** RICHARD HERZ and MAX SCHUBERT (to General Aniline Works). U. S. 1,788,297, Jan. 6. Products suitable for use as intermediates in the manuf. of dyes of the indigo series are obtained by treating at a temp. exceeding 100° a 1-aminoarylene thiazole compd. wherein arylene means a substituted residue of the benzene series or a residue of the naphthalene or anthracene series substituted or not and wherein the benzene nucleus adjacent to the thiazole ring in the 4-position to the azole N atom is either substituted or blocked with a concd. caustic alkali soln. The production of 1-ethoxy-4-amino-3-thionaphthol (which may be pptd. as its Zn salt) is described and from this compd. by condensation with chloroacetic acid there may be obtained 1-ethoxy-4-aminonaphthalene-3-thioglycolic acid, the anhydride of which m. 227–8°. 1-Methyl-2-amino-5-chlorobenzene-3-mercaptan yields 1-methyl-2-amino-5-chlorobenzene-3-thioglycolic acid. 1-Amino-4-ethoxybenzene-2-mercaptan yields 1

amino-4-ethoxybenzene-2-thioglycolic acid. Details are given of the production of these compds. Cf. *C. A.* **24**, 2470, 3248.

Anthraquinone derivatives. Soc. pour l'ind. chim. à Bâle. Fr. 687,299, Dec. 27, 1929. New derivs. are prepd. from products of the general formula

in which one X signifies a nitro group and the other X an NHR_1 group, R_1 signifies H or an alkyl group, R_2 an aromatic or hydroaromatic group, by transforming the NO_2 group into NHR_3, in which R_3 signifies H, an alkyl, aralkyl or hydroaromatic group. The products may be sulfonated, alkylated or acylated as desired. The products dye acyl- or alkyl-celluloses or Zapon lakes in fast shades of blue to greenish blue. Several examples are given.

Diazoamino compounds. I. G. Farbenind. A.-G. (Eugen Glietenberg, Wilhelm Neelmeier and Josef Haller, inventors). Ger. 510,441, May 1, 1928. Water-sol. diazoamino compds. *useful in dyeing and printing* are prepd. by the action of aromatic diazo compds. on sulfonated or carboxylated compds. of the formula $NHR_1(R_2)$, where R_1 is the residue of an aliphatic or hydroaromatic carboxylic acid or of an aralkylsulfonic or carboxylic acid, and R_2 is the same as R_1 or an alkyl, aralkyl or hydroaromatic residue, or the residue of an alkyl sulfurous acid. An acid-binding agent is included in the reaction mixt. Thus, the diazo compd. from 2-amino-4-chlorotoluene may react with sarcosine. Other examples are given also.

Quinoline derivatives. I. G. Farbenind. A.-G. (Werner Müller and Wilhelm Schnurer, inventors). Ger. 510,431, Mar. 13, 1929. Nitroquinoline derivs. *useful as azo dye components* are prepd. by treating 2,4-dihydroxyquinoline or *N*-substituted 1,2-dihydro-4-hydroxy-2-ketoquinolines in H_2SO_4 with HNO_3. Examples are given.

Carbazolesulfonic acid derivatives. I. G. Farbenind. A.-G. Fr. 688,603, Jan. 27, 1930. Intermediate products for dyes are prepd. by diazotizing aminocarbazolesulfonic acids or their derivs. and replacing the diazo group by anions such as OH, Cl, Br, I, CN, SCN, SH, AsO_3H_2. Examples and lists of compds. which may be prepd. are given.

Aromatic methyleneamino compounds. Myrtil Kahn, Wilhelm Schepss and Edwin Zinn (to General Aniline Works). U. S. 1,781,982, Nov. 18. *Dye intermediates* are obtained by the interaction of a halomethyl deriv. of a hydroxy compd. of the aromatic series such as chloromethyl-*o*-cresotic acid with an aromatic amine such as 2-amino-8-naphthol-6-sulfonic acid, at room temp. Several examples are given of the production of different products which, in general, are whitish powders sol. in dil. alkalies, producing azo dyes with diazo compds. and having most probably the following general formula: 4,3,5-(HO)XYC$_6$H$_2$CH$_2$NRR′, wherein R stands for a benzene or naphthalene radical contg. at least one of the groups —OH and —SO_3H, R′ stands for H, alkyl or aryl, X means H or a substituent and Y means H or the carboxy group.

Carbazoleindophenol compounds (dye intermediates). Fritz Ballauf, Friedrich Muth and Albert Schmelzer (to General Aniline Works). U. S. 1,781,966, Nov. 4. By causing primary and sec. aliphatic amines to react, in the presence of condensing agents, with carbazolecarboxylic acids, carbazolecarboxylic acid alkylamides (mono- or dialkyl) are obtained and these condense easily with nitrosophenols. The different carbazolecarboxylic acids can be used, the carbazole-1- and the carbazole-2-carboxylic acids being the most easily available. Details are given of the production of 6-(*p*-*hydroxyanilino*)-*N,N-dimethyl-2-carbazolecarboxamide* which is a reddish blue powder, sol. in concd. H_2SO_4 with a reddish blue color; it is readily reduced to the corresponding leuco compd. when treated in alk. soln. with Na_2S or NaSH.

Dyes and intermediates. I. G. Farbenind. A.-G. Brit. 334,565, April 6, 1929. 5,8-Dihalo-1,2-benzanthraquinones are converted into dyes or dye intermediates by at least partially replacing the halogen atoms by the same radicals of the general formula X—R, in which X represents —NR′— (R′ being H or an org. residue), —S— and R represents H or an org. residue; *e. g.*, 5,8-dichloro-1,2-benzanthraquinone (which may be prepd. as described in Brit. 332,192 (*C. A.* **25**, 215)) is condensed with *N*-methyl-*p*-toluenesulfamide, *p*-toluenesulfamide, *p*-toluidine, *p*-thiocresol, aminoanthraquinone

or phenol, producing dyes of various colors suitable for use on cellulose acetate rayon, and yielding wool dyes by sulfonation.

Dyes and intermediates. I. G. FARBENIND. A.-G. Fr. 689,968, Feb. 14, 1930. Compds. which are either dyes or intermediates for dyes are prepd. by treating with nitrating agents the derivs. of 1,1'-dianthracyl, in which the 2 $C_{14}H_{10}$ radicals are joined to one another by at least one ring of 6 members in such a way that one is the mirror image of the other and replacing, if necessary, the NO_2 groups in the products by other groups. The NO_2 groups may be reduced to NH_2 groups, the H atoms of which may be replaced by any groups or the NH_2 groups themselves may be replaced. The nitration may be carried out in the presence of solvents or diluents such as $PhNO_2$, or HNO_3 alone or mixed with H_2SO_4 may be used. A large no. of examples of the nitration of *meso*-benzo-, *allo-meso*-naphtho-, and *meso*-anthra-dianthrone and their derivs., and the conversion of the products to other derivs. is given.

Dyes and intermediates. SCOTTISH DYES, LTD. Fr. 689,583, Feb. 7, 1930. See Brit. 333,506 and 333,507 (*C. A.* **25**, 604).

Dyes and intermediates. I. G. FARBENIND. A.-G. (Fritz Mayer and Karl Zahn, inventors). Ger. 512,237, Sept. 8, 1927. See Brit. 296,761 (*C. A.* **23**, 2579).

Dyes and intermediates of the anthracene series. I. G. FARBENIND. A.-G. (Arthur Wolfram and Emil Hausdörfer, inventors) Ger. 512,229, Dec. 31, 1927. See Brit. 303,375 (*C. A.* **23**, 4579).

Dye intermediates. I. G. FARBENIND. A.-G. (Erich Fischer, inventor). Ger. 506,441, Oct. 19, 1926. Compds. of the formula 1-X-2(or 4)-Y-3,5-$(NO_2)_2C_6H_2$, in which X is $—SO_2N(R)$aryl or —CON(R)aryl (R being an alkyl or an aralkyl group) and Y is a halogen, are prepd. by the action of sec. aromatic amines on the corresponding compds., in which X is SO_2(halogen) or CO(halogen). Examples are given describing the prepn. of *4-Cl-3,5-*$(NO_2)_2C_6H_2SO_2NPhMe$, m. 161°, and *4-Cl-3,5-*$(NO_2)_2C_6H_2CONPhMe$, m. 150°.

Dye intermediates. I. G. FARBENIND. A. G. (Max A. Kunz and Karl Kobetz, inventors). Ger. 508,396, Oct. 14, 1927. Halo-*ms*-naphthodianthrones are prepd. by treating *ms*-naphthodianthrone or its derivs. with a halogen or a halogenating agent in the presence or absence of catalysts and preferably in the presence of a solvent or diluent. Like products may be prepd. by treating halo-*ms*-benzodianthrones with acid condensing agents, *e. g.*, $AlCl_3$, or with oxidizing agents in acid soln. Examples are given.

Dye intermediates. H. A. E. DRESCHER, J. THOMAS and SCOTTISH DYES, LTD. Brit. 334,166, Feb. 21, 1929. 1-Amino 2-chloro- and 2-amino-3-chloro anthraquinone are obtained by treating the urea of 3'-amino-4'-chloro-2 benzoylbenzoic acid with H_2SO_4 under ring-closing conditions, and sepg. the mixt. of products by diln.

Coloring agents. I. G. FARBENIND. A. G. Fr. 689,050, Jan. 29, 1930. Soln. of dyes in org. solvents contg. rubber or its transformation products or condensation products of butadiene hydrocarbons are used for coloring wood, glass, artificial substances, films, artificial silk, etc.

Dyeing fibers. ECLIPSE TEXTILE DEVICES, INC. Ger. 510,801, Jan. 8, 1929. App. is described for locally dyeing textile fibers which can absorb liquids.

Dyeing fibers with azo dyes. I. G. FARBENIND. A.-G. Fr. 36,748, Mar. 22, 1929. Addn. to 670,216 (*C. A.* **24**, 1988). Azo dyes are obtained on fiber by printing on the article in the usual manner the condensation products of diazo, tetrazo or diazotized aminoazo compds. with secondary bases, along with suitable coupling component and developing by treating with acid agents. Examples are given.

Dyeing vegetable fibers. CHEMISCHE FABRIK, VORM. SANDOZ. Fr. 690,280, Feb. 10, 1930. The dyeing properties of cotton or other vegetable fibers are altered by boiling the undyed fibers with aq. alk. lyes to which may be added OH derivs. of the aromatic or alicyclic series, and afterward treating them with solns. of aromatic carboxylic or sulfonic chlorides or halides of P in indifferent liquids not miscible with water.

Dyeing animal fibers with ester salts of leuco vat dyes. DURAND ET HUGUENIN SOC. ANON. Brit. 334,508, May 27, 1929. In dyeing animal fibers with ester salts of leuco vat dyes as described in Brit. 218,649 (*C. A.* **19**, 579), emulsifying agents are added which remain sol. and efficacious in an acid medium such as "Sapamines" or sulfonic acids of fatty acids such as those described in Brit. 288,612 (*C. A.* **23**, 605). The emulsifying agents are preferably added to the acid oxidizing baths used for development, and dyeings are obtained which are very fast to rubbing. Examples are given.

Dyeing textiles. HENRY DREYFUS. Fr. 36,696, April 22, 1929. See Brit. 316,529 (*C. A.* **24**, 1991).

Dyeing textiles. BRITISH CELANESE, LTD., and G. H. ELLIS. Brit. 334,518,

April 29, 1929. In producing discharge effects, textile materials are impregnated with a substance of acid reaction prior to the application of a discharging agent for a coloring matter or coloring matter component, and discharge is effected in the presence of the acid substance, which may be oxalic, tartaric, citric, salicylic, benzoic or naphthoic acid, a benzenesulfonic acid or sulfonic acid of phenol, naphthalene or naphthols or an acid salt such as $Al_2(SO_4)_3$ or $ZnSO_4$. The process is applicable to cotton, silk, regenerated cellulose and cellulose esters and ethers or mixts. of these materials. Numerous details and examples are given.

Dyeing and finishing textiles, etc. HERMANN HELTEWIG. Ger. 510,802, Oct. 12, 1928. The treated pieces of fabric are carried through rollers over the dyeing or finishing vats and the squeezed-out liquor is removed and replaced by fresh liquor.

Dyeing cellulose esters or ethers. HENRY DREYFUS. Fr. 688,755, Jan. 23, 1930. Cellulose acetate or other esters or ethers of cellulose are dyed by oxidizing on the material an aromatic amine in the presence of an amt. of mineral acid chemically equiv. to this amine and in the presence of a supplementary substance of acid reaction such as a mineral or org. acid or acid salt or salt having an acid reaction. In an example, $PhNH_2$ in the presence of HCl and AcOH is oxidized with a chlorate to give a deep black. Other examples are given.

Dyeing cellulose esters and ethers. I. G FARBENIND. A.-G. (Erich Fischer and Carl Erich Muller, inventors). Ger. 505,885, Oct. 19, 1926. A brown color is produced by using a dye free from free SO_3H groups, formed by the condensation of *p*-aminodiphenylamine or its homologs or substitution products, with dinitrohaloaryl groups of the general formula 2,4,6-X C_6H_2Y, where Y is a halogen and at least 2 of the X groups are NO_2 groups and the third is an optionally substituted group, the completed dye contg. at least 1 COOH group. In an example, the dye 2-(*p*-$PhNHC_6H_4$-NH)-3,5-$(NO_2)_2C_6H_2COONa$ dyes acetate silk a yellow brown. Many other examples are given.

Black dyeing of cellulose esters and ethers with disazo dyes. ERIC A. SPRIGHT (to Imperial Chemical Industries Ltd.). U. S. 1,780,320, Nov. 4. Full black shades are obtained on "acetate silk" or like materials by direct dyeing with secondary disazo dyes of the general formula:

where one X represents H and the other X represents H or a sulfonic group, R represents the coupled residue derived from diazotized amines of the glass comprising aniline and the homologs and halogenated derivs. of the same, and Y represents an OH or NH_2 group. Dyes of this type may be made by diazotizing aniline or equiv. amine, for instance, toluidine, xylidine, chloroaniline, chlorotoluidine, etc., and coupling with 1-naphthylamine or the 6- or 7-sulfonic deriv. thereof. The aminoazo compd. thus formed is diazotized and coupled with 1,5-naphthylenediamine or 1,5-aminonaphthol to form the disazo dye. Various details and examples are given.

Coloring cellulose esters and ethers. MAX J. THEUMANN (to E. I. du Pont de Nemours & Co.). U. S. 1,789,122, Jan. 13. A lake is formed *in situ* in a soln. of the cellulose deriv. and the colored cellulose deriv. is then isolated (suitably by pptn. with water).

Coloring cellulose esters and ethers. MAX J. THEUMANN (to E. I. du Pont de Nemours & Co.). U. S. 1,789,121, Jan. 13. A soln. of cellulose acetate or other cellulose deriv. to be colored is treated with substances such as $FeCl_3$ and $K_4FeC_6N_6$ which are capable of reacting together to form an inorg. coloring material, and the mass is treated with a liquid (suitably with water in the treatment of an acetone soln. of cellulose acetate) miscible with the solvent but in which the cellulose deriv. and coloring material are insol., so that pptn. of a colored product is effected.

Dyeing regenerated cellulose materials. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 689,799, Feb. 12, 1930. See Brit. 328,706 (*C. A.* **24**, 5510).

Dyeing regenerated cellulose materials. RAINALD BRIGHTMAN (to Imperial Chemical Industries Ltd.). U. S. 1,789,134, Jan. 13. Disazo dyes, some of which are now obtained by tetrazotizing 1,5-diaminonaphthalene and coupling with one mol. of a phenol or naphthol or a carboxylic or sulfonic deriv. thereof or an aminonaphtholsulfonic acid and one mol. of another coupling component, other than 2-amino-5-naphthol-7-sulfonic acid or a deriv. thereof, are applied to the dyeing of a regenerated cellu-

lose rayon, for instance, viscose rayon in even shades. For the production of the best results there must be present in the dye mol. at least one sulfonic acid group for each naphthalene nucleus combined as a coupling component. Several examples are given of dyes giving various violet, blue, brown and maroon shades, and details of the dyeing process are given.

Dyeing knitted and woven fabrics. CHARLES CALLEBAUT and JULIEN DE BLICQUY. U. S. 1,788,980, Jan. 13. The articles are immersed in a pool of dyeing liquor and air is alternately introduced into the body of liquor at opposite sides of the pool so as to produce successive rotation of the body of liquor and articles immersed in it in opposite directions. App. is described.

Dyeing and printing. DURAND & HUGUENIN S. A. Ger. 512,438, April 27, 1928. See Brit. 310,478 (*C. A.* **24**, 732).

Dyeing or printing textiles. DURAND & HUGUENIN S. A. Fr. 36,764, April 22, 1929. Addn. to 571,264. Textiles are dyed or printed by oxidizing, in acid medium esters of leuco derivs. of vat dyes with Cu salts, such as the sulfate, as oxidizing agent Examples are given.

Dyeing and printing cellulose esters and ethers. BRITISH CELANESE, LTD., and G. H. ELLIS. Brit. 334,543, April 29, 1929. The chlorates used as discharging agent in the process described in Brit. 312,655 (*C. A.* **24**, 973) are replaced wholly or in part by chromates, and colored discharges may also be obtained by incorporating resistant insol. or difficulty sol. coloring matters of the nitrodiarylamine, aminoanthraquinone or acidylaminoanthraquinone series in the oxidizing discharge pastes, which may contain chlorates, chromates or oxidizing agents such as those specified in Brit. 315,005 (*C. A.* **24**, 1522). Numerous details and examples are given.

Printing textiles. SOC. PAULE A. LEONARD. Fr. 688,858, Jan. 25, 1930. In printing by the method of "discharge colors," salts called reserves, such as the Na salt of *m*-nitrobenzenesulfonic acid, which neutralize the action of the discharge agent are applied to certain parts of the previously colored cloth.

Printing wool. I. G. FARBENIND. A.-G. Fr. 689,346, Feb. 3, 1930. Colors which may be discharged are obtained on wool by printing with monoazo dyes obtained by coupling 4-nitro-1-aminobenzene-2-sulfonic acid with sulfonic acids of 2-aminonaphthalene or their *N*-alkyl derivs. An example is given.

Printing woolen fabrics with ester salts of leuco vat dyes. I. G. FARBENIND. A.-G. Brit. 334,419, Oct. 11, 1928. In a process such as is described in Brit. 298,648 (*C. A.* **23**, 3111), reducing agents are added to the printing pastes, for obtaining colored discharges. Examples are given

Vat assistant for use in dyeing. JEAN G. KERN and CHARLES J. SALA (to E. I. du Pont de Nemours & Co.). U. S. 1,782,122, Nov. 18. Either the dye paste or the dye bath is mixed with substituted aliphatic amines contg. hydroxyl groups in the aliphatic radicals, which are very strongly basic and possess a high degree of solubilizing power. The general formula for substances of this class is $R_1R_2NC_nH_{2n}OH$, R_1 and R_2 representing either an alkyl group $C_nH_{(2n+1)}$, H, or a hydroxyalkyl group $C_nH_{2n}OH$. Also any one of these substituents may be replaced by a compd. contg. the group $C_nH_{2n-1}(OH)_2$.

Dyeing apparatus. ARCHIBALD J. HALL. U. S. 1,789,040, Jan. 13. Structural details are described of a closed vat app provided with pipe connections for air or gas supply and proportioned flow to waste a part of the air or gas.

Apparatus for dyeing hanks. GIOVANNI RAMELLA-LEVIS. Ger. 510,082, Aug. 31, 1926.

Variable-speed apparatus for dyeing yarn hanks. G. S. LORD. Brit. 334,[illegible], March 26, 1929. Structural features.

Apparatus for dyeing artificial silk or other materials in skeins. E. BLASCHKE. Brit. 334,382, Aug 9, 1929. Structural features.

Machine for bleaching, dyeing, etc., yarn in loose or spooled form. F. G. SCHLUMACHER and JOHANN J. MÜLLER. Swiss 140,679. June 12, 1929. Details are given.

System of tanks and dipping apparatus for dyeing, washing or other treatments of materials by immersion in liquids. M. DASSONVILLE. Brit. 334,730, March 9, 1929. Structural features.

Dye-bath table. I. G. FARBENIND. A.-G. Fr. 688,960, Jan. 27, 1930. A table for reading directly in a rapid manner the amt. of dyes and chem. products necessary for the prepn. of dye baths is described; it consists of a flat rectangular box in which a plate slides.

Mill for pulverizing dyes, etc. ALFRED E. G. MACCALLUM. Ger. 510,526, Jan 17, 1929.

Treating textiles. ACETA G. M. B. H. Fr. 689,984, Feb. 14, 1930. The elec. charge on textile fibers made of cellulose esters or ethers is reduced during their prepn. or manuf. by impregnating the fibers with a mixt. of oils or fats to which org. bases sol. in the oil such as dibutylamine or triethanolamine are added.

Treating textiles. CAMILLE DREYFUS. Fr. 690,406, Feb. 21, 1930. The properties of textiles, particularly those composed of, or contg. cellulose derivs. such as cellulose acetate, are improved by treating them with a dispersion of rubber latex and preferably by an inorg. or org. pigment or other substance which is practically insol. in water. Examples are given of the use of rubber latex and rubber latex with graphite or ZnO.

Treating textiles. CAMILLE DREYFUS. Fr. 36,860, May 2, 1929. Addn. to 636,608 (*C. A.* **23**, 719). Cloth is given the appearance of lace, gauze or other perforated effects by submitting cloth contg. threads composed of filaments derived from cellulose acetate or other org. derivs. of cellulose and threads composed of vegetable fibers such as cotton or linen, to a carbonization wholly or in parts. The cloth may also contain animal fiber such as natural silk or wool, and designs may be produced by the application of different mixts.

Bleaching textile fibers. I. G. FARBENIND. A.-G. Fr. 690,220, Feb. 19, 1930. Textile fibers are bleached by alternate treatments with H_2O_2 and Cl (acid) with intermediate washings with NaOH lye.

Sizes for textiles. AGATHE WOLFF. Ger. 510,084, Mar. 24, 1928. Highly viscous sizes or finishes for textiles are prepd. by treating starch with malt exts. having a strong liquefying action but little or no saccharifying action. Suitable exts. are those obtained at a higher temp. than usual (up to 70°)

Apparatus for treating textiles, particularly linen, with ozone. OSCAR HOFFMANN. Fr. 689,377, Feb. 4, 1930.

Finishing fabrics. HEBERLEIN & CO., A.-G. Brit. 334,756, Oct. 12, 1928. Fabrics formed, at least in part, of vegetable fibers are pressed at a temp. above 100° and subsequently treated with one or more swelling baths (suitably H_2SO_4, H_3PO_4, HNO_3, alkali lye, ammoniacal Cu oxide or $ZnCl_2$ soln.) to give the material a linen-like appearance.

Washing and fulling fabrics as a finishing operation in their manufacture. EMIL MUSSDORF. U. S. 1,788,777, Jan. 13. The fabrics are passed between the washing and fulling rollers in the direction of the weft of the fabric.

Treating vegetable fibers. THE TWITCHELL PROCESS CO. Fr. 690,434, Feb. 22, 1930. The natural impurities contained in vegetable fibers are eliminated by heating the fibers in an aq. soln. contg. true "mahogany" sulfonates.

Maceration of flax, etc. E. N. FITZNER and N. N. ZUIRIN. Russ. 15,593, Dec 17, 1927. An enzyme for the maceration of flax, etc., is obtained by treating hemp stalks with water for 2-3 hrs. at 60-70°.

A bacterial method of maceration and cottonization of flax, hemp, etc. E. N. FITZNER and N. N. ZUIRIN. Russ. 36,464, Dec. 4, 1928. The maceration is carried out in the usual way with a maceration liquid prepd. from the stalks of *Urtica dioica* or of *Urtica urens*.

Charging silk. RENÉ CLAVEL. Fr. 37,045, June 14, 1929. See Brit. 332,778 (*C. A.* **25**, 422).

Working up waste silk. I. G. FARBENIND. A.-G. (Ernst Rossner, inventor). Ger. 510,480, Nov. 15, 1928. Waste silk is dissolved in H_3PO_4 to form a relatively stable soln. which is coagulated by means of a salt soln. and spun into filaments, hairs, bands, etc. Thus, silk waste 1 may be dissolved in 85% H_3PO_4 10 parts and the soln., after allowing it to stand, may be spun into a satd. soln. of NaCl contg. 5-10% of $HCONH_2$.

Viscose silk. I. G. FARBENIND. A.-G. Fr. 689,712, Feb. 11, 1930. The quality of viscose silk and its aptitude for dyeing are improved by treating the freshly prepd. viscose silk still in the wet state by an aq. soln. of ammoniacal-CuO free from caustic alkali under such conditions that it only dissolves a small percentage of the dry wt. of the viscose.

Artificial silk. RENÉ CLAVEL. Fr. 36,920, May 13, 1929. Addn. to 629,042. Textiles of, or contg., artificial silk are charged by treating with a metallic salt such as $SnCl_4$, drying and introducing them directly without washing into a bath of fixing acid such as a soln. of NaH_2PO_4 to which may be added acids or acid salts as well as protective colloids. Instead of NaH_2PO_4, a soln. of Na_2HPO_4 made acid by the addn. of acids or acid salts may be used.

Artificial threads, films, etc. HENRY DREYFUS. Fr. 689,800, Feb. 12, 1930. Filaments, threads, textiles, etc., of diminished luster, of, or contg., cellulosic esters or

ethers are made by forming in the material a non-colloidal metallic compd. by the reaction of a pptg. agent on a sol. metallic compd. The cellulosic material is preferably in a swollen state. Examples are given of the pptn. in the material of $BaSO_4$.

Films or ribbons of cellulose derivatives. F. Loozen. Brit. 334,525, Jan. 12, 1929. Films or ribbons of great length, such as those formed of viscose or cellulose acetate, are cut into the form of threads, fibers or wadding suitable for spinning or other working. App. and various mech details are described.

Pile fabrics. Albert W. Drobile. U. S. 1,788,989, Jan. 13. A pile fabric has loops of the pile contg. animal fiber united to the backing fabric by a solidified pliable compn. resulting from the coagulation *in situ* on the backing of an aq. dispersion of rubber permeating the interstices of the fabric.

Artificial wool. Frédéric G. Maillard. Fr. 689,891, April 18, 1929. Vegetable fibers are given the appearance of wool by steeping in a bath contg. alkali carbonate at 60° and then treating with Na sulforicinate with the addn. of an alkali carbonate. The product is then bleached and dressed.

Mothproofing wool, etc. I. G. Farbenind. A.-G. Fr. 686,721, Dec. 16, 1929 See Brit. 324,962 (*C. A.* **24**, 3912).

Fabric for covering aircraft. Isadore M. Jacobsohn and Starr Truscott. U. S 1,788,394, Jan. 13. A flexible fabric impermeable to gases comprises a rubberized base fabric and a film of plasticized reverted cellulose or "cellulose rubber." Cf. *C. A.* **24**, 2617.

Apparatus for drying and finishing tubular textile fabrics by treatment with hot air. Emile B. Bates. U. S. 1,789,093, Jan. 13. Structural features.

Reconditioning dry-cleaning solvents. R. R. Stolley Corp. Brit. 334,208, May 27, 1929. The dry-cleaning solvent is prepd for re-use by passing it upwardly through a caustic alkali soln. and "Darco" activated charcoal, potash or other cleansers and then through water and $CaCl_2$. App. is described. Cf. *C. A.* **24**, 2900.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Studies in the plasticity of paints. F. H. Rhodes and W. J. Jebens. *J. Phys. Chem.* **35**, 383–404(1930).—Water, Na oleate and Ca oleate increase the yield value and decrease the mobility of paints prepd. from nearly neutral linseed oil. The same changes are observed when water is added to the above paints in the presence of either soap Fatty acids increase the consistency of a ZnO paint, while small quantities of water counteract the effects of the fatty acids. Fatty acids have little effect upon white lead paints. $ZnSO_4$ does not change the flow characteristics of ZnO paints. Heating at 150° for 1 hr. reduces the consistency of a ZnO paint made from acid linseed oil.

S. Bradford Stone

Chalking (of paints). III. Is chalking to be considered as desirable or not? Richard Kempf. *Farben-Ztg.* **36**, 553–5(1930); cf. *C. A.* **25**, 422.—The desirability of chalking depends both upon the purpose of the paint (whether gloss or mat effect is desired) and upon whether chalking or cracking be the lesser evil (if it is assumed that one or the other takes place). It is undesirable for any surface with which people come into phys. contact. It is desirable when high reflection factors are wanted, *e. g.*, on oil tanks, tunnels, sign posts, etc.

G. G. Sward

Field tests on quick-drying house paints. H. A. Gardner and L. P. Hart. *Am. Paint & Varnish Mfrs.' Assoc.*, Circ. No. **374**, 32–52(1931).—A preliminary report is made on exposure tests on a no. of quick-drying house paints conducted at Gainesville, Fla. The vehicles included bodied tung-linseed oil mixts., glycerol phthalate compns., other synthetic resins and nitrocellulose lacquers. Formulation, spreading rates and comments on brushing properties are given.

G. G. Sward

Measurement of abrasion resistance. I. Paints, varnishes and lacquers. A. E. Schuh and E. W. Kern. *Ind. Eng. Chem., Anal Ed.* **3**, 72–6(1931).—A method of measuring the abrasion resistance of materials in the form of thin films is described While designed primarily for the study of paints, lacquers and varnishes, it should be useful also for a large no. of other materials, *e. g.*, the wearing quality of electrodeposits The principle of the method is a modification of Gardner's falling-sand method. Essentially it consists in the following: Carborundum powder of uniform particle size is admitted at a const. rate to a directed stream of air under const. pressure and humidity and the resulting Carborundum-air blast allowed through a nozzle to impinge upon a film

of the test material mounted at a fixed angle. The wt. of Carborundum required to wear through a unit thickness of material is taken as the abrasion resistance of the material. The present method has made possible measurements of high precision when uniform and accurately measured films are observed. D. THUESEN

Comparison of some light sources for accelerated weathering tests. G. G. SWARD AND L. P. HART. *Am. Paint & Varnish Mfrs.' Assoc.* Circ. No. 375, 53–8(1931).—The outdoor weathering of a no. of different coating materials was compared with that produced by accelerating devices using (1) a pair of 13-amp. enclosed carbon arcs, (2) a 50-amp. flaming C arc using "Sunshine" carbons, (3) a 50-amp. flaming C arc using therapeutic "C" carbons and (4) a low-pressure Hg-in-quartz arc. The accelerated cycle consisted of continuous light and a water spray twice each hour. Typical outdoor failures were obtained with (1) and (2), the latter being 2 to 3 times faster than the former. Failure by chalking predominated with 3 and 4 even in materials which failed by checking out of doors. A combination of arcs to produce both checking and chalking is suggested. The operating costs are approx. (1) 22 cents; (2) and (3) 21 cents; and (4) 8.5 to 13 cents per hr. These do not include capital investment or time of operator. G. G. SWARD

A dressing plant for "Bideford Black." H. M MORGANS. *Bull. Inst. Mining Met* 315, 7–8, 9–22(1930); cf. *C. A.* 25, 423.—Discussion. ALDEN H. EMERY

Arsenic in writing materials. G. G. KAPPELLER. *Z. Untersuch. Lebensm.* 60, 213–5(1930).—Of 14 samples of violet C paper, 5 contained As. Three of German origin contained 0.95–3.8 g. per 100 g., or 16.1–59.6 mg. per sheet, while 2 American papers contained 0.9–3.0 g. of As per 100 g., or 19.8–45.4 mg. per sheet. Two English violet typewriter ribbons contained 0.5–1.1 g. of As per 100 g. or 5.8–15.4 mg. per m. Four violet pencils and 2 aniline ink-powders were free from As. The possibility of contamination through use of oxides of As in the manuf. of fuchsin, methyl violet, Prussian blue, etc., is discussed. C. R. FELLERS

The possibilities of inorganic paint vehicles. NÖEL HEATON. *J. Oil & Colour Chem. Assoc.* 13, 330–40(1930).—Org. paint vehicles possess more or less satisfactory durability on most types of surfaces except plaster. Fresco is limited to a certain type of plaster and must be applied within a few hrs. of the plaster. Stereochromy is likewise limited to a certain plaster, is tedious and costly Si esters offer promise in that they may be applied on any type of plaster and at any time. The chief disadvantages are poor storageability and poor working properties. G. G. SWARD

Drying oils. XIV. Rate of oxidation of linseed oil at 160°. J. S. LONG AND H. D. CHATAWAY. *Ind. Eng. Chem.* 23, 53–7(1931); cf. *C. A.* 24, 4173.—Samples of raw linseed oil (I), linseed oil acids and synthetic esters of oleic and linolenic acids were blown with O in a closed app. supplied with an electromagnetic circulating pump. The H_2O and CO_2 evolved during oxidation were absorbed in H_2SO_4 and soda lime. The hydrocarbons evolved were burned to H_2O and CO_2, which were likewise absorbed. The rate of O absorption of each material is plotted against cc. of O absorbed. Gelation of the pure oil occurred after 5 hrs. when approx. 12.5% of O had been absorbed. Diln. of the O stream with 50% N increased the time of gelation to over 9 hrs. and decreased the O absorption by 5.7%. Samples contg. Mn, Co or Pb driers gelled sooner than the pure oil but absorbed approx the same total amt. of O. 0.032% of Co caused rapid absorption during the first hr. but the rate soon fell to that of the pure oil. No marked difference was noted between 0.1% and 0.3% of Pb. Triolein (II), linolenic triglyceride (III), the synthetic triglycerides of the mixed fatty acids of linseed oil, linseed oil-free acids and the pentaerythritol ester of linolenic acid (IV) gelled in 12.1, 2.9, 4.1, 7.3 and 2.3 hrs. and absorbed 18.5, 11.4, 11.8, 15.4 and 8.8% of O, resp. In one expt. IV was partially oxidized, heated 7 hrs. in N and again oxidized. At gelation it had absorbed only 5.3% of O. Gelation ensues when a certain degree of complexity of the mols. is reached and the influence of the degree of unsatn. or oxidation and of the presence of driers is secondary. Increasing rates of oxidation at the beginning of each expt. is explained as due to the gradual disappearance at 160° of antioxidants naturally present in the oil Though the free linseed oil acids gelled slowly and absorbed much O, the presence of 15% of them accelerated the gelling of I. A second set of expts. was made with I, II, III and IV in which the wt of volatile products and gain in wt. of the samples were measured and ultimate analyses of the gel made The results of the latter indicate that gelation occurs when each :C=C: of II has acquired 2 atoms of O to form peroxide groups, when each mol of I or III has acquired 1 peroxide group and before each mol. of IV has acquired such a group. H. K. SALZBERG

Influence of antioxidants on the rate of oxidation of linseed oil. I. Hydroquinone. A. M. WAGNER AND J. C. BRIER. *Ind. Eng. Chem.* 23, 40–9(1931).—After a

futile attempt to obtain reliable results by exposing hydroquinone-linseed oil systems in the form of films, W. and B. resort to blowing 400-g. charges of the samples under rigidly controlled conditions with air and expressing the state of oxidation in terms of *n* and Wijs I values. The app. is described in detail. Runs were made at 30° and 100° on pure raw linseed oil and on samples of the same oil contg. varying amts. of hydroquinone (I) or of oxidized oil and I. At 100° the oxidation rates of 7 samples of the pure oil were practically identical until an I value of 130 was reached (starting values 179–84), when they began to differ widely, gelation occurring at an I value of approx. 110. At this temp. no induction period was noticeable. At 30° the induction period was approx. 450 hrs. and gelation occurred at an I value of 120. The oxidation rate at 100° is much greater than at 30° after the induction period. Preliminary runs showed that the vapor pressure of an antioxidant is an important factor in its effect, especially when blowing at the higher temps. Concns. of I of less than 1:10,000 had no appreciable effect at 100°, but at 30° concns. as low as 1:100,000 had a measurable effect. At both 100° and 30° the induction period was prolonged to an extent directly proportional to the concn. of I, but the rate of oxidation following this period was the same for all samples and the pure oil. Addns. of I made during the induction period to samples already contg. I in 1:1000 concn. at 100° prolonged the induction period but had no effect on the rate of oxidation following this period. Addns. of I after the start of active oxidation had no influence whatever. At 30°, however, addns of I made at any time during the oxidation of samples already contg. I prolonged the oxidation. Therefore, the velocity of oxidation dets. the degree to which the antioxidant will be effective, and above a crit. velocity no effect is observable. The addn. of 1.25% of partially oxidized linseed oil (II) to pure oil or to oil contg. I in 1:1000 concn. shortened the induction period by an amt. proportional to the amt. of II added at both 30° and 100°. The presence of excess I at 100° prolongs the induction period to gelation, oxidation having progressed slowly during the entire period. At 30°, however, oxidation during the induction period is too slow to be detected. Polymerization does not seem to occur during the induction period.

H. K. Salzberg

Technic of the modern industrial varnish industry. Franco Grottanelli *Atti III congresso naz. chim. pura applicata* **1930**, 122–33. —A review. E. M. S.

Blooming of varnish films. Hans Wolff. *Farben-Ztg.* **36**, 505–6(1930).—Higher magnification shows that the crystals described by Krumbhaar (*C. A.* **25**, 220) are in reality a honeycomb structure of the film. Blooming of films is assocd. with low water absorption. The cases described by K. confirm this conclusion. The conditions of drying are as important as the compn. of the varnish. *E. g.*, many varnishes that do not bloom when dried under normal atm. conditions may be caused to bloom when dried in a dry atm., *e. g.*, an oven. G. G. Sward

The problem of mat varnishes. H. Deckert. *Farben-Ztg.* **36**, 453, 504–5(1930).—The labor involved in producing rubbed finishes has been largely eliminated by the production of coatings which dry with a mat surface. The effect is obtained by the incorporation of materials such as waxes, metallic soaps and pigments. Waxes produce soft drying varnishes difficult to handle. The best results are obtained with metallic soaps, especially with a highly basic Al palmitate characterized by insoly. in mineral thinners. The optics of mat finishes is briefly discussed. G. G. Sward

Cadmium pigments in cellulose lacquers. Gg. Siebert. *Farben-Ztg.* **36**, 506–7 (1930).—Cd pigments in lacquer vehicles are more light fast than the chromes. They are non-bleeding, but when exposed to the weather they fade, being converted to Cd carbonate. G. G. Sward

Study of "run" amber. I. C. Plonait. *Farben-Ztg.* **36**, 555–6(1930).—Seventy-five % of the amber obtained from the State Amber Works at Palmnicken is rendered suitable for varnish making by "running." The product is sepd. according to color in 5 grades with av. acid and sapon. nos., resp., as follows: (1) 23.6, 47.07; (2) 16.4, 45.44; (3) 17.5, 44.98; (4) 12.4, 53.92; (5) 12.8, 19.05. G. G. Sward

Solvents and non-solvents for nitrocotton. Fritz Zimmer. *Farben-Ztg.* **36**, 701 (1930).—Solvent power for nitrocotton seems to be assocd. with a —CO— group found in esters, ethers and ketones. Alcs., except MeOH and EtOH, do not dissolve nitrocotton. However, alcs. do not ppt. nitrocotton as do the non-solvent hydrocarbons. The various theories of solvents for nitrocotton are briefly stated. The formation of solvate complexes with nitrocellulose is suggested. G. G. Sward

Solvent problem. Alfred Heinemann. *Farben-Ztg.* **36**, 270(1931); cf. preceding abstr.—Before the solvate theory can be accepted, many phenomena, such as the relation of viscosity to the size of solvated mols., must be explained. Note by Zimmer. G. G. Sward

The photoactivity of rosin. G. NORKIN AND B. SHADIN. *Chem. Umschau Fette, Oele, Wachse Harze* **37**, 340–1(1930).—Exptl. results on the photoactivity of Russian rosin lead to these conclusions: Increase in surface increases photoactivity, powdered rosin affecting the photographic plate most, both Russian and U. S. rosins being used. The active rays emitted by rosin pass readily through air, less through thin white paper, least through black paper; a glass plate is entirely opaque. A list of 18 references is appended. P. ESCHER

The color reactions of colophony. M. MARINI. *Peintures, pigments, vernis* **6**, 830–3(1929).—A review. B. H.

The optical rotation of resins. III. Optical rotation as a criterion for genuine pressed amber. C. PLONAIT. *Chem. Umschau Fette, Oele, Wachse Harze* **37**, 342–4 (1930); cf. *C. A.* **25**, 832.—Artificial resins have a sp. gr. of above 1.22 and n over 160; amber has a sp. gr. of 1.050–1.096 and n 1.55–1.58. Copals have the consts. of amber but they may be distinguished by their appearance, hardness, soly. and S content. Mixts. of varying amts. of copals with amber were extd. by P. with various solvents, but no quant. results could be obtained from their soly. Sharp distinctions, however, were found by polarizing the ether, benzene or alc. exts. of these mixts. in solns. of dioxane or ether at 20° in the 50-mm. or 100-mm. tube, *viz:* amber ext. solns. showed in all cases a reading of +20.5 to +29.1, while the copals (Zanzibar and Congo) showed a strong *l*-rotation; mixts. of amber and copal fell between these extremes and a detn. is therefore made possible by this method. P. ESCHER

Natural resins—synthetic resins. W. NAGEL. *Metallbörse* **20**, 2133–4, 2190–1 (1930).—The properties of rosin, shellac and copal are compared with those of phenol-formaldehyde condensation products and coumarin resins, particularly in respect to the *suitability of elec. insulating materials.* Expts. have shown that the elec. insulating ability of materials prepd. from phenol-formaldehyde resins, such as insulating card boards, falls considerably when a spark once was permitted to take place. This was not observed with materials prepd. from shellac. Conclusion: The decompn. products of phenol formaldehyde resins are conductive, those of shellac indifferent. A slight increase in temp. induces stickiness to films of shellac substitutes, while the elasticity remains practically the same. Films of natural shellac under the same conditions increase in elasticity but do not stick. This is explained by the ability of films of natural shellac to retain considerably more solvent than the substitutes. The mechanisms of the formation of various synthetic resins are briefly discussed. D. THUESEN

The manufacture of synthetic resins. L. V. REDMAN. *Can. Chem. Met.* **15**, 13–5 (1931). Phenol-formaldehyde condensation products are considered principally. Heat hardening condensation products are termed "resinoids" and the permanently fusible type, "Novolaks" (now termed "resins"). Commercially the resinoids are much more important. Seven basic forms of phenolic condensation products are listed and recent developments touched upon. W. H. BOYNTON

Colorimetric method for determining turpentine oil in the atmosphere (KORENMAN) 7. Multivalent metallic salts of half esters of phthalic acid (U. S. pat. 1,779,654) 10. Cellulose products [lacquers] (Fr. pat. 690,215) 23. Rubber composition with linseed oil (U. S. pat. 1,789,062) 30. Purifying waxes, resins and hydrocarbons (Fr. pat. 690,556) 27.

RIDDELL, GEORGE L.: **A Physico-Chemical Study of Certain Aspects of Lithographic Printing.** London: London School of Printing. 82 pp.

WENZEL, JOHANNES, AND ALVENSLEBEN, KONRAD: **Die Beseitungung der beim Tauch- und Spritzlackieren entstehenden Dämpfe.** 2nd ed., revised. Berlin: J. Springer. 47 pp. M. 3.90.

Paints. WILLY BÖHMER. Fr. 689,438, Feb. 5, 1930. A silicate paint resistant to hydrocarbons, damp, heat and cold contains, *e. g.*, minium 10, litharge 2, glycerol (27 sol. Bé.) 3 and sol. glass (36° Bé.) 9 parts

Paints. I. G. FARBENIND. A.-G. Fr. 691,201, Mar. 5, 1930. Paints resistant to weather are made by choosing the amt. of metallic base in the paint sufficiently high to transform the free fatty acids, the glycerides and the fatty acids finally formed into metallic soaps.

Pigments. I. G. FARBENIND. A.-G. Fr. 689,462, Feb. 5, 1930. Pigments having

a high degree of dispersion are obtained by forming the pigments in a viscous aq. soln. of a cellulose deriv. such as methylcellulose, which is coagulated by heating.

White lead. E. C. WALKER. Brit. 334,751, Oct. 11, 1929. Corroding gases such as CO_2 and vapors of HOAc and water are used for treating Pb buckles passing down a stack inclined at an angle just greater than the angle of rest of the buckles so that the latter roll gradually down the bed. App. and various details are described. Cf. *C. A.* **24**, 252.

Titanium compounds. LUCIEN PELLERAU, MAURICE JACMART and GUENHAIL LE BRIS Fr. 690,348, Feb. 21, 1930. Pure TiO_2 for *pigments* is prepd. by heating a mixt. of ilmenite, Na_2CO_3 and anthracite dust to 800° in a rotating furnace and the product is allowed to fall into water. The product is washed and the soln. carbonated to recover Na_2CO_3. The Fe is removed by dil. H_2SO_4. The powder obtained after filtering and drying is treated at 150-180° with H_2SO_4 to dissolve the TiO_2 and then the temp. is raised to 200-225° so that the H_2SO_4 attacks the coal to produce SO_2, which reduces the Ti to the titanous form, the Fe remaining in the ferrous state. On cooling, the product is taken up with warm water and hydrolyzed. Fr. 690,349 describes the heating of ilmenite with Na_2CO_3 to 700-800°. The product is washed to eliminate sol. salts and to transform the Na titanate to TiO_2.

Apparatus (with grinding cylinders) for grinding pigments. GUSTAV A. VASH U. S. 1,788,964, Jan. 13. Structural features.

Emulsion comprising clay and calcium silicate. ROY CROSS (to Silica Products Co.). U. S. 1,788,706, Jan. 13. An emulsion which may be used in cheap *paint mixts.* comprises a major proportion of gelatinizing clay and a minor proportion of Ca silicate or portland cement in finely divided form adapted to form a gel with water. Oil, asphalt, ZnO, etc., also may be added.

Ink. JOHN H. CLEWELL (to Canadian Industries, Ltd.). Can. 307,397, Jan. 6, 1931. An ink comprises diacetone ale., a nigrosine base and orange shellac. The rate of drying is increased by the addn. of acetone and decreased by the addn. of triacetin. This ink is used for marking motion-picture films and cellulose ester articles.

Quick-drying ink suitable for intaglio printing. E. WINSHIP. Brit. 334,570, Aug. 23, 1929. A homogeneous mixt. is formed from water, gilsonite or the like and petroleum or coal tar distillate, and pigment. Details of manuf. are given. Cf. *C. A.* **25**, 833.

Varnish. MYRON E. DELANEY (to The Bakelite Corp.). Can. 307,653, Jan. 13, 1931. A coating compn. comprises a varnish of the oleoresinous type contg. chlorinated naphthalene and Al powder. Cf. *C. A.* **25**, 833.

Varnish. I. G. FARBENIND. A.-G. Ger. 510,937, April 11, 1929. The oil and fats neutralized by C_2H_4O described in Ger. 504,128 (*C. A.* **24**, 5523) are used for the manuf. of varnishes. Thus, linseed oil neutralized with C_2H_4O is mixed with ZnO, a diluent and a Pb Co drying agent (*e. g.*, naphthenic acid Pb Co). Other examples are given.

Varnish for wires. I. G. FARBENIND. A.-G. Fr. 689,104, Jan. 30, 1930. Wires are covered with a varnish composed of condensation products of dicarboxylic acids and ethers, if necessary in admixt. with other polybasic acids and polyhydric alcs. in the molten or dissolved state, and the varnish is then hardened. Thus, the condensation product obtained from 2 mols. of diglycolic acid, 1 mol. of succinic acid and 2 mols. of glycerol is dissolved in a mixt. of the Et ether of glycol, the Me ether of glycol, MeOH, AcOMe and AcOEt. The varnish is coated on to wires after the addn. of ZnO and cobalt blue. Other examples are given.

Colored polymerized vinyl ester varnishes. I. G. FARBENIND. A.-G. Brit. 331,115, Dec. 3, 1928. Polymerized vinyl ester varnishes such as those of vinyl acetate are colored by adding substances such as 1,4-diamino-2,3-diphenoxyanthraquinone (red), 1,4-di-*p*-toluinoanthraquinone (green), 1-methylamino-4-*p*-toluinoanthraquinone (greenish blue), or 1,4-di-*p*-toluino-8-hydroxyanthraquinone (olive green); substances such as Al or Cu or other metal powders, softening or hardening agents, solvents and various fillers also may be added.

Varnish and lacquers. WILLIAM H. MOSS (to Camille Dreyfus). Can. 307,989, Jan. 20, 1931. A varnish or lacquer contains cellulose acetate, a resin prepd. from phenol and aldehyde in the presence of $SnCl_2$, and a volatile solvent.

Lacquers and similar coating compositions. I. G. FARBENIND. A.-G. Brit. 334,567, May 6, 1929. Coating compns. suitable for application to materials such as wood, natural or imitation leather, brickwork, asbestos, paper or textile fabrics, etc. by brushing, printing, immersion or spraying are prepd. by emulsifying solns. of water-insol. cellulose derivs. such as nitrocellulose, cellulose acetate or various other simple or

mixed cellulose esters or ethers in substantially water-insol. org. solvents, with aq. solns. of water-sol. colloids (other than albumins) such as polymerized vinyl alcs., starch, urea-formaldehyde resins, or Al salts of conversion products of phenol-formaldehyde condensation products with halogenated fatty acids, with various coloring and modifying agents, etc. Numerous details and examples are given.

Colored lacs. Soc. anon. pour l'ind. chim. à Bâle. Swiss 140,719, Dec. 8, 1928. A greenish yellow light-fast lac is obtained by using a dye of the general formula 2-*p*-alkoxyphenylazo-*p*-cresol (OH = 1). In the example, the alkyl group is CH_3 and the dye is used in making up a Japan lacquer.

Apparatus for drying lacquered goods, etc., with a circulating current of hot ozonized air. Luftheizungs- und Abgasverwertungs-G. m. b. H. Ger. 510,791, Jan. 13, 1928. Addn. to 506,121 (*C. A.* **25**, 424).

Drying oil. I. T. Osnos. Russ. 48,948, June 10, 1929. A mixt. of oil and metal oxides which correspond to the following quantities of metals, Pb 2.25–3.50%, Mn 0.75–1.00% and Co 0.25–0.40%, is passed first through a colloid mill and then heated as usual.

Coating composition containing nitrocellulose. Earle C. Pitman (to E. I. du Pont de Nemours & Co.). U. S. 1,788,406, Jan. 13. A soln. of reduced viscosity suitable for use as an enamel or lacquer comprises nitrocellulose of a N content of 10.11.5%, of a stability of 30 min. (German test) and which is completely sol. in 95% EtOH.

Colored glaze. Paul Hofer and Alfred Schmid. Fr. 689,173, Jan. 31, 1930. A colored glaze fast to light is produced from artificial resins free from phenols or their condensation products and halogens even in small quantities, *e. g.*, condensation products of urea or thiourea and CH_2O and a pigment.

Plastic compositions. Bakelite Corp. Fr. 689,015, Jan. 28, 1930. Plastic compns. are composed of a reactive resinoid (*e. g.*, a phenolic resinoid) and a fibrous filling material, which is impregnated with the resinoid.

Resinous condensation products. Howard W. Matheson and Frederick W. Skirrow (to Canadian Electro Products Co., Ltd.). U. S. 1,788,772, Jan. 13. A fusible and sol. condensation product such as may be derived from C_2H_2 and phenol, together with added aldehyde such as paraldehyde, forms a compn. capable of being dild. by solvents or softened by heating to liquid, semi-liquid or plastic condition for casting, molding, surface coating or impregnating other materials, and also capable of being converted by the action of heat and pressure to a hard, infusible condition.

Condensation products of resin and phenol. Arnold Doser and Alfred Thauss (to I. G. Farbenind A.-G.). U. S. 1,788,371, Jan. 13. By heating a mixt. of colophony and PhOH with dil. H_2SO_4 there is obtained a yellowish resin-like product, insol. in water, sol. in aq. alk. solns. and in org. solvents, which is suitable for sulfonation to produce *tanning agents*. U. S. 1,788,372 describes a process by which the condensation product from colophony and PhOH is treated with H_2SO_4 monohydrate to form a yellowish resin like substance, the alkali metal salts of which are sol. in water and suitable for use as *tanning*.

Ester resins. I. G. Farbenind. A.-G. (Gerhard Balle, inventor). Ger. 510,446, June 20, 1928. Addn. to 463,842 (*C. A.* **22**, 4262). Hard resins sol. in hydrocarbons are prepd. by heating phenol-aldehyde resins or phenol alcs. with an excess of resin acid, and esterifying the excess of acid in the product by treatment with C_2H_2, preferably in the presence of a solvent and a catalyst, *e. g.*, $HgSO_4$. Examples are given.

Artificial resins. Bakelite G. m. b. H. Fr. 690,335, Feb. 20, 1930. Resols are united with oils drying in the air by taking condensation products of phenols and aldehydes, which may be hardened, and mixing them with the oils which have been totally or partially oxidized or which contain their products of oxidation, preferably in the presence of a solvent mixt. capable of dissolving both. The solvent is eliminated by distn. in a vacuum.

Molding articles such as butter dishes from synthetic resins. Brookes & Adams, Ltd., and A. E. Brookes. Brit. 334,258, June 1, 1929. Mech. features.

Synthetic resins. Bakelite Corp. Fr. 689,014, Jan. 28, 1930. A coating compn. is composed of a resinous product obtained by the reaction of a mixt. of *p*- and *o*-hydroxydiphenyl with an agent contg. methylene or by the reaction of a phenolic substance contg. 2 or more C_6H_4 rings with an agent contg. methylene and a fatty oil. Examples are given.

Synthetic resins. Bakelite Corp. Fr. 690,457, Feb. 22, 1930. A compn. drying in the air to form a hard coating or film is made by the reaction of a phenolic substance with a fatty oil such as abrasin, adding an agent contg. mobile CH_2 or hexamethylenetetramine in amt. sufficient to obtain a resinoid and producing a fresh reaction until a

more viscous product or jelly is obtained. The product is ground and dispersed or suspended in a solvent, and, if necessary, the reaction is continued until the resinoid has little or no penetrating power when it is applied as a coating on an indicator paper.

Synthetic resins. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 36,837, Apr. 24, 1929. Addn. to 616,463. Synthetic resins are prepd. by condensing polyhydric alcs. and polybasic acids in the presence of org. compds. of multivalent metals known under the generic name of soaps. Examples are given of the use of Co linoleate, Al stearate, Fe or Bi lactate, etc.

Synthetic resins. LOUIS NOLET. Fr. 690,588, May 1, 1929. Condensation products of urea and CH_2O are obtained by using oxides, hydroxides or basic salts of heavy metals as catalysts, the medium being previously rendered acid to methyl orange but not to tournesol. This acidity is obtained by the addn. of NH_4 salts or salts of aromatic or aliphatic amines either to the mixt. of urea and CH_2O or to the urea before mixing with the CH_2O.

Synthetic resin compositions. H. HÖNEL. Brit. 334,572, May 8, 1929. Thin or thick oils, or gelatinous or rubber-like materials, suitable for molding or for use in coating, impregnating or binding compns., are obtained by reaction of an ester with a primary condensation product of low mol. wt. obtained by the use of an alk. catalyst from formaldehyde and a phenol in which not more than 2 of the reactive positions *o*-, *o*- and *p*- to the phenolic group or groups are unsubstituted (no solvent or dispersing agent being present during the reaction with the ester). Water is evolved during the reaction Low-mol. crystalloid esters such as those of benzoic acid and univalent alcs. yield thin or viscous oils or gelatinous masses. Esters of the same alcs. with polybasic acids give gelatinous products with less of the phenol-CH_2O compd. More suitable are fusible esters of rather high mol wt. obtained from mixts. of polybasic and monobasic carboxylic acids and a polyhydric alc. such as glycerol or from a polybasic acid, with or without a monobasic acid, and a mixt. of polyhydric and univalent alcs. Some of these are converted into rubber-like products by reaction with a very small proportion of the phenol-CH_2O compd. Glycerides, fats, oils, waxes and esters of phenols with inorg. acids also may be used. A large number of details and examples are given.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Lipoids—phosphatides—fats. RICHARD ROSENBUSCH. *Chem.-Ztg.* **54**, 965-7 (1930).—Definitions are discussed. It is difficult to draw sharp lines of division between the 3. L. E. GILSON

Determination of total fatty acids. A. K. CHURCH. *Oil and Fat Ind.* **8**, No. 1, 23–5(1931).—See *C. A.* **25**, 426. E. C. K.

Moisture determination in fats and soaps by the distillation method. J. DAVIDSOHN. *Chem.-Ztg.* **54**, 934–5(1930).—Detns. of water in fats and soaps are usually low, even with the recently adopted (in Germany) new app., in which the xylene is refluxed while the water distils over. Apparently the soap retains some of the water and liberates it only after adding a quantity of water-free oleic acid. Similar low results are obtained with butter, but correct values are found when water-free oleic acid is added either at the beginning or during the distn. P. ESCHER

X-ray investigations of oils, fats and lubricants. JEAN J. TRILLAT. *Metallwirtschaft* **9**, 1023–8(1930).—The length of the carbon chain of fatty acids increases linearly with the no. of carbon atoms. By means of the crystal rotation method applied to a drop of liquid, it can be shown that fatty acids are oriented on the surface of water or glass, since the surface of the liquid has a crystal structure while the interior of the liquid does not. The attraction of the acid radical of the fatty acid for the surface of metals accounts for the lubricating qualities of the oil, inasmuch as the COOH group neutralizes to a certain extent the intense electromagnetic field radiated from the metal and thereby reduces friction. MALCOLM DOLE

Complementary applications of the phthaleinoscope. I. Determination of the acidity of oils and fats. II. Titration in colored alkaline media. BRUÈRE. *Ann. fals.* **23**, 532–4(1930); cf. *C. A.* **24**, 3193.—The method has been adapted to the titration of the acidity of oils or fats by using as solvent a 2:1 mixt. of $CHCl_3$ and 95% alc. 15 cc. of the solvent is placed in the cell, the indicators are added, the solvent is brought to neutrality, the oil or fat is added and dissolved and the acidity titrated with 0.1 *N* alc. KOH. The use of iso-PrOH instead of $CHCl_3$-EtOH is being studied, as it would

have the 2-fold advantage of using a single solvent and of permitting the use of an aq. standard alkali. For alkalimetric detns., place a measured vol. of the alk. soln. in the soln., add an excess of standard acid and titrate with standard alkali. A. P.-C.

Action of antioxygens in the oxidation of unsaturated fatty oils. II. Inhibitory effect of diphenylamine, diphenylguanidine and hydroquinone. BUNNOSUKE YAMAGUCHI. *Rept. Aeronautical Research Inst., Tokyo Imp. Univ.* **5**, 287–305(1930); cf. *C. A.* **24**, 4410.—The antioxygenic effects of these compds. on olive oil were studied. Diphenylamine lowers the initial rate of oxidation in a remarkable degree, although it does not inhibit the oxidation as completely as unsym. diphenylhydrazine. The oxidation of the olive oil contg. diphenylamine starts initially with a very small but sensible rate corresponding to the same length of time as the period of incubation for the oil contg. no antioxygen. After the antioxygen has been lost from the oil in the course of oxidation, the reaction then proceeds unimolecularly as for the pure olive oil The value of the velocity coeff. of the unimolecular reaction is slightly smaller than that for pure olive oil. This seems to be due to the effect of a certain weak antioxygen, which may be gradually formed from diphenylamine in the course of oxidation either through its oxidation, through thermal decompn. or through some reaction with certain oxidation products of oil. Hydroquinone acts as a strong inhibitor, prolonging the induction period in a remarkable degree just as unsym. diphenylhydrazine. The length of the period thus prolonged depends upon the added amt. of hydroquinone, and the former increases almost in direct proportion to the latter. After this period the oxidation proceeds as for oil contg. no antioxygen. The antioxygenic power of diphenylguanidine resembles the curve for the oil with diphenylamine. The results of the expts. can be explained by the theory of the mechanism of inhibition developed in a previous paper. On the basis of this theory an equation has been deduced to calc. the form of the velocity curve for the oxidation of oil contg. diphenylamine, and it has been shown that the equation agrees with the results of expts.

E. SCHERUBEL

The fatty oil of the seeds of Couepia grandiflora, Benth., one of the so-called oiticica oils. J. VAN LOON AND A. STEGER. *Chem. Umschau Fette, Oele, Wachse Harze* 37, 337–40(1930).—The name oiticica oil is applied to oil from many species of nuts; the name couflor oil is proposed for the oil from *Couepia grandiflora*, Benth., of Brazil. The av. nut weighs 5.8 g. and the kernel 4.2 g. The kernels grind easily, yielding on extn. with petr. ether 57.7% oil, or 41.3% on the basis of the nuts, and 28.4% hulls and 30.3% extn. residue. The oil is viscous, light yellow, of wood-oil odor and wood-oil properties; it is perfectly clear at 51° but solid constituents sep. on standing at room temp.; d^{15} = 0.9440, acid no. 0 92, sapon. no. 188.3, ester no. 187.4, R.-M. no. 0.56, true I no. 231 (the highest I no. of any known oil), n_D^{21} 1.5184, n_D^{46} 1.5090, n_D^{70} 1.5002, unsaponifiable 0.30–0.41, satd. acids 11.21–11.63%. The high n indicates highly unsatd. acids with conjugated double bonds. The acids have true I no. 243, acid no. 196.7, mean mol. wt. 285.2, m. 70–78°, n_D^{78} 1.4998. The satd. acids have sapon. no. 210, mean mol. wt. 266, m. 56–57.5°, suggesting a ratio of 35% stearic acid to 65% palmitic acid P. ESCHER

New method of preparing soluble oils. T. VOLTZ. *Bull. soc. ind. Mulhouse* **96**, 636–42(1930).—(Based on sealed communication of Charles Sunder.) One hundred g castor oil was esterified by treating for 12 hrs. at 30° with the product of the reaction of 200 g. chlorosulfonic acid and 1.5 l. of pyridine. The *trisulfuric ester of castor oil*, $C_3H_5(OOC\text{-}C_{17}H_{32}OSO_3Na)_3$ (I), was isolated by neutralizing with Na_2CO_3 and distg. *in vacuo* at 40°, and purified by soln. in abs. alc. One hundred g. of (I) was sapond. at the boil for 3 hrs. with a 10% soln. of NaOH; by diln., acidifying with H_2SO_4, and salting-out, $HOOCC_{17}H_{32}OSO_3Na$ (II) was obtained as cryst. needles. By boiling (II) with HCl in alc., neutralizing with Na_2CO_3, evapg. off the alc., and extg. with ether, $C_2H_5COOC_{17}H_{32}OH$ (III) was obtained as a mobile liquid. By sapon. of (III), ricinoleic acid (IV) was prepd. and identified by its Ba salt. As a check, (IV) was esterified with chlorosulfonic acid and pyridine to give (II). Similar esterification of (III) gave $C_2H_5COOC_{17}H_{32}OSO_3Na$. The ester (I) showed indications of desirable properties in *alizarin lakes*. I. H. O.

The "coin test" for oils. New technic. Reaction of various oils and particularly of oils extracted with carbon disulfide. Spontaneous sulfuration of olive oils. R. MARCILE. *Ann. fals.* **23**, 527–30(1930).—The following technic is recommended for the test: In 40 cc. of oil contained in a 60-cc. Erlenmeyer flask place a piece of Ag foil 6 mm. × 12 cm., place in an oven at 115–20°, and observe the immersed portion of the foil after 24 and 48 hrs. Peanut, cottonseed, soy-bean and sunflower seed oils gave a neg. reaction. Colza oil gave a slight pos. reaction, equiv. to that of olive oil contg. 10% of refined CS_2-extd. oil. Extra and superfine olive oils gave a neg. reaction; some burning-grade olive oils gave a more or less marked pos. reaction before, but not after, refining.

Tunisian refined CS_2-extd. olive oils all gave intense reactions, though some of the oils were 10 yrs. old, and could be detected when present to the extent of only 5% in pressed oils. Various French and Spanish unrefined burning-grade oils gave clear pos. reactions, but only about $^1/_4$ as strong as those of the corresponding Tunisian oils. No reaction was obtained with unrefined oils obtained by extn. with trichloroethylene or with petr. ether. When allowed to stand in contact with impure water which may undergo putrefaction, olive oil can form stable compds. with the H_2S produced, and these are not removed by agitation with alk. solns. A. PAPINEAU-COUTURE

Corn-oil preparation and usefulness. G. A. MOORE. *Oil & Fat Ind.* **8**, 15–6(1931) E. H.

Determination of unsaponified oil in soap or fatty acids. E. LESTER SMITH *Analyst* **56**, 9–14(1931).—To test qualitatively, decomp. the fat with dil. HCl, skim off the fat without attempting to dry it, weigh out 1 g., melt it if necessary, and add 60 ml of 65% alc. (by vol.) and 1 ml. of 7.5 *N* NH_4OH. Run a blank with pure fatty acid and compare. A turbidity indicates unsapond. oil. The test can be made quant. by dissolving 0.5 g. of the fatty acid in 20 ml. of 90% alc. and adding 0.5 ml. of NH_4OH. Measure the vol of water necessary to produce incipient turbidity, finally comparing the result with that obtained with standards. If the procedure is carefully followed in the manner described in the paper, 0.05% of unsapond. oil can be detected. W. T. H

Conductometric determination of soap in technical baths. H. C. STUHLMANN AND H. FABER. *Chem. Fabrik* 1930, 531-2.—The method depends on the sharp rise in cond at the moment the soap is all neutralized. J. H. MOORE

Bile as a valuable filler for soap. W. OBST. *Seifensieder-Ztg.* **57**, 853-4(1930). A review of the literature. O considers oxgall a valuable filler for soaps, especially for use on woolen goods, on account of its emulsifying power and its mild action on the fiber P. ESCHER

Laundry experiments. W. KIND. *Seifensieder-Ztg.* **57**, 888-9(1930). K. points out the importance of the hardness of water in washing tests, not only in the soap soln proper but also in the rinsing water; this leads to insol. soaps in both cases. Oxycellu lose detn. and the bleaching-out of methylene blue are unreliable criteria in washing expts. P. ESCHER

Einheitliche Untersucungsmethoden für die Fett- und Wachsindustries. Teil 1. 2nd ed. Teil 2. 1st Ed. Stuttgart: Wissenschaftliche Verlags 241 pp. Linen, M 15. Reviewed in *J. Intern. Soc. Leather Trades Chem.* **15**, 51(1931).

Extracting fatty materials. JEAN M. DE GIRVES. Fr. 690,579, May 1, 1929 Fatty materials are extd. from grape residues by the same process as is used for extg. the seeds, with dichloroethylene as solvent.

Bleaching fats, fatty acids and waxes. I. G. FARBENINDUSTRIE. Russ. 17,496, Sept. 13, 1926. Fats, fatty acids and waxes are treated with a mixt. of chlorate and permanganate in an acid soln.

Sulfonated fatty acids. N. V. CHEMISCHE FABRIEK SERVO and MEINDERT D ROZENBROEK. Fr. 688,637, Jan. 21, 1930. Fatty acids of high mol. wt. or their derivs are sulfonated to a high content of combined H_2SO_4 by carrying out the sulfonation in the presence of chlorides of S, $COCl_2$, $SOCl_2$, SO_2Cl_2, BCl_3, H_3BO_3 or its anhydride, or mixed anhydrides of AcOH or its homologs with inorg. acids such as H_3BO_3, H_2SO_4, chromic acid, oxyacids of P, sulfoacetoacetic acid, etc. Examples are given.

Sulfonated oils. SOC. ANON. POUR L'IND. CHIM. À SAINT DENIS. Fr. 690,022, Feb. 15, 1929. Sulfonated oils, which are stable toward lime and magnesian waters and toward acid solns., are prepd. by sulfonating fatty acids or their glycerides in the presence of a catalyst with a large excess of H_2SO_4 at a temp. below 0°. An example is given of the sulfonation of ricinoleic acid.

Apparatus for distilling oils from plants at low pressure. FELIX EYSSERIC and FÉLIX BLANCHARD. Fr. 36,915, May 8, 1929. Addn. to 625,972.

Castor oil. ÉMILE A. ANDRÉ. Fr. 36,877, Oct. 30, 1928. Addn. to 677,360 (*C. A.* **24**, 3124). The process of Fr. 677,360 for obtaining several qualities of castor oil by selective soln. is applied to used castor oil.

Saponifying glycerides and other esters. VAMAN R. KOKATNUR. Ger. 510,427, April 23, 1926. See Brit. 251,290 (*C. A.* **21**, 1367).

Purifying waxes, resins and hydrocarbons. I. G. FARBENIND. A.-G. Fr. 690,536, Feb. 25, 1930. Resins, waxes or hydrocarbons (with the exception of montan wax, carnauba wax and like vegetable waxes and paraffin) are purified by mixing them, preferably in soln., with more than 50% of their wt. of decolorizing powder, such as active C, and extg. with solvents.

Saponaceous cleansing compositions. S. ZIMMERMANN. Brit. 334,177, Oct. 2, 1928. A fat or fatty acid is saponified with less than the stoichiometric quantity of alkali such as NaOH in the presence of PrOH or iso-PrOH; solvents such as benzene, gasoline, terpenes or halogenated hydrocarbon derivs. are added before, during or after saponification. Various details, proportions, etc., are given.

Soap. HENKEL & CIE. G. M. B. H. (Wilhelm Pape, inventor). Ger. 512,428, Nov. 24, 1927. Soap contg. less than 80% of fatty acid is improved by addn of a little $(NH_4)_2S_2O_8$. The $(NH_4)_2S_2O_8$ may be formed *in situ*, *e. g.*, from $(NH_4)_2CO_3$ and $Na_2S_2O_8$. Cf. *C. A.* **24**, 4948.

Solution tank suitable for supplying soap solutions for washing. ROBERT C. MURRAY (to Economics Laboratory, Inc.). U. S. 1,788,404, Jan. 13. Structural features.

Bleaching soap. CHARLES F. SCHUMAKER (to Mathieson Alkali Works). U. S. 1,788,848, Jan. 13. Soap is subjected to a milling operation in admixt. with solns. of NaOCl and formaldehyde.

Detergent compositions. DOUGLAS D. BROOKS. Fr. 689,051, Jan. 29, 1930. See Brit. 326,755 (*C. A.* **24**, 4943).

28—SUGAR, STARCH AND GUMS

J. K. DALE

Mill sanitation and juice deterioration. A critical study of acidity increase, mill sanitation and possible loss during the extraction of the sucrose from the cane. R. H. KING. *Sugar News* **11**, 640-55(1930).—Data obtained by allowing juices to remain for varying periods indicate that the acidity increases rapidly after 2 hrs.' standing, the increase going up to 100% after 16 hrs. The p_H decreases less rapidly. After 68 hrs. acidity increased from 2.2 to 12.70, the p_H decreased from 5.31 to 4.75, glucose increased from 1.21 to 4.61, while the apparent purity dropped from 87.67 to 50.83. The acidity, p_H and drop in apparent purity from mill to mill seems to be related to the quality of the cane and the maceration water applied. Use of hot water at 3-hr. intervals together with periodic removal of accumulations of bagasse and sediment, and the use of deep, sloping juice pans and troughs will reduce mill juice decompn to a min. The use of lime or chemicals is not recommended.

V. G. LAVA

Filtration of cold raw cane juice. C. F. ARMSTRONG. *Intern. Sugar J.* **37**, 576–7 (1930). In studying the adaptability of the metafilter to the Javan sugar industry, some expts. were carried out based on Zerban's work (*C. A.* **14**, 1920) on the clarification of cane juice without chem. treatment. Hyflo-Supercel was employed instead of the ordinary kieselguhr used in the former expts. Cold raw juice was collected from the mill strainer, mixed with 1% Hyflo-Supercel (calcd. on the Brix of the juice) and filtered through a small lab. filter. At low pressure a rapid filtration was obtained, but the filtrate was cloudy and of a light brown color. The cloudy filtrate was then heated to 70°, and sufficient milk of lime added to bring the p_H to 8 and then sufficient SO_2 to bring it back to 6.8. The filtrate was brilliant, clear, of a light yellow color and its purity showed a rise of 2° above the original purity of the raw juice. On account of the clogging of the filter cloths a metafilter of 2 sq. m. was used, and this was first precoated with Hyflo-Supercel, 500 g. per sq. m. of filter. The first filtrate, when treated with CaO and SO_2 as above described, filtered with the rapidity of water, and the amounts of the clarifying agents used amounted to about one-quarter of that ordinarily required in a sulfitation factory. If the pressure of filtration of the cold raw juice rose above 10 lb. per sq. in., the filtrate was clear but filtration practically ceased. It is evident, therefore, that as a result of the peculiar nature of the solids of cold raw juice there is a film formation.

W. L. OWEN

Conductometric formula for determining the ash in both raw and refinery sirups and molasses. LOUIS SATTLER AND F. W. ZERBAN. *Ind. Eng. Chem., Anal. Ed.* **3**, 38-40(1931); cf. *C. A.* **21**, 2394; **24**, 1242, 1243, 4418.—The methods previously de-

scribed required different formulas for raw sugar products, on the one hand, and refinery products on the other. By substituting H_3PO_4 for the HCl formerly specified, it has been possible to devise a method which gives accurate results for both classes of products with one formula. Each 100 ml. of soln. to be used for the measurement of the initial cond. contains 0.5 g. of the product plus 4.5 g. sucrose. If K is the corrected sp. cond. $\times 10^6$ at 20° of this soln., K_2 that of 200 ml. of the original soln. with the further addn. of 5 ml. of 0.25 N KOH and K_3 that of 200 ml. soln. plus 5 ml. N H_3PO_4, the % ash in the sample equals $0.01937\ K - 0.002249\ K_2 - 0.00121\ K_3 + 3.07$. The corrected sp. cond. at 20° of 5 ml of the KOH soln. plus 200 ml. cond. water should be 0.001422, and that for the H_3PO_4 soln. dild. in the same way should be 0.001925. A nomograph is shown from which the % ash may be read off directly. F. W. ZERBAN

Ash and electrical conductivity of refined cane sugars. F. W. ZERBAN AND LOUIS SATTLER. *Ind. Eng. Chem., Anal. Ed.* **3**, 41–3(1931); cf. preceding abstr.—The % ash (sulfated less 10%) in refined cane sugars such as granulated and remelt, contg. less than 0.3% ash, is found by dissolving 25 g. of the sugar in cond. water to a vol. of 100 ml., detg. the sp. cond. of the soln. at 20° and multiplying the result, after correcting for the cond. of the water, by 530. To find the % ash in soft sugars, 5 g. is used in 100 ml. soln., as with raw sugars; the appropriate av. factor which varies from place to place may then be detd. for each refinery, or else the following general method may be employed: Five g. of soft sugar, or if the ash is expected to be above 1%, 2.5 g. soft sugar plus 2.5 g. sucrose, is used for every 100 ml. of soln., and the sp. cond. is measured at 20°. This figure, multiplied by 10^6, is K. A 2nd cond. detn. is made on 200 ml. soln. plus 5 ml. 0.25 N HCl, as previously described for raw sugars; this figure $\times 10^6$ is K_1. The % ash equals $0.001695\ (0.913\ K + 193.5 - 0.1\ K_1)$. If 2.5 g. soft sugar plus 2.5 g. sucrose has been used, the final result must be multiplied by 2. The same method is also applied to remelt sugars contg. from 0.3 to 2% of ash. If the ash is higher, 0.5 g. product plus 4.5 g. sucrose is used, and the result is multiplied by 10, as with sirups and molasses. The article concludes with practical recommendations for equipment and methods to be used in routine work on all types of cane products. F. W. ZERBAN

New scheme for the withdrawal of diffusion juice. M. B. LUISYANSKII. *Zhur. Sakharnoi Prom.* **4**, 298–9(1930).—Design of the scheme with explanation is given. V. E. BAIKOW

Advantageous limits for beet drying. V. P. CHEFRANOV. *Zhur. Sakharnoi Prom.* **4**, 277–81(1930).—A technical and mathematical discussion. V. E. BAIKOW

Thermocontrol of beet dryers. I. I. EGOROV. *Zhur. Sakharnoi Prom.* **4**, 281–8 (1930). V. E. BAIKOW

Efficiency of evaporating stations. G. G. GABERMAN. *Zhur. Sakharnoi Prom.* 4, 288–94(1930). V. E. BAIKOW

Vapor heating at Pioneer. G. W. TOMPKIN. *Repts. Assoc. Hawaiian Sugar Technologists 9th Ann. Meeting*, Oct. 20–3, 1930, 19–20.—The low price of sugar calls for greater economy in the use of steam. At Pioneer, vapor from the 3rd effect is re-used in 2 juice heaters, with a resultant saving of 130 lb. of steam per ton of cane, and of 25% in the amt. of condenser water. F. W. ZERBAN

Slow-boiling massecuites. S. A. WICKEY. *Repts. Assoc. Hawaiian Sugar Technologists 9th Ann. Meeting*, Oct. 20–3, 1930, 5–7.—This difficulty, experienced at Koloa for a no. of yrs., has finally been traced to the overliming of settlings, and has been overcome by liming them to only 8.0 to 8.3 p_H. Blank boilings have been completely eliminated by this means. The lime added to juices from certain fields has also been reduced, with good effect; only sufficient lime is added to assure a sirup of 7.0 p_H. F. W. ZERBAN

Seeding low-grade massecuites. G. F. MURRAY. *Repts. Assoc. Hawaiian Sugar Technologists 9th Ann. Meeting*, Oct. 20–3, 1930, 3.—In factories with limited low-grade pan capacity a seed strike, sufficient for 8 to 16 low-grade strikes, may be boiled as follows: C molasses is drawn into the pan and it is boiled under 24 to 25 in. vacuum to heavy string proof (92–93 Brix). Steam is immediately shut off, the vacuum raised to normal by increasing injection water and 1 lb. of screened, powd. sugar is drawn into the mass. After 10 to 15 min., when the grain is large enough to be seen with a small microscope, the steam is again turned on, and the strike fed with small charges of sirup and molasses, tightening up between charges, until the grain has reached the proper size, after which the strike is finished to 200 cu. ft. on molasses, and struck at about 90 Brix to a receiving tank below. F. W. ZERBAN

Cooling coils in crystallizers. J. E. BIELA. *Repts. Assoc. Hawaiian Sugar Technologists 9th Ann. Meeting*, Oct. 20–3, 1930, 9.—Both the time necessary for graining low grade massecuites, and the purity of the resulting molasses, have been reduced at Kohala

by equipping half of the crystallizers with cooling coils. The water is turned on into the coils 24 hrs. after the strike is dropped, and kept on until 1 day before drying. The massecuites are then dild. to make them ready for drying. F. W. ZERBAN

A study on the incrustations in the evaporation apparatus. PIETRO BALBONI. *Ind. saccarif. ital.* **23**, 259–63(1930).—The evapg. capacity is decreased by 10–15% by incrustations. In the water evapd. at the start of the sugar season and after a month in a 4-unit plant a reduction was noted of 0.8, 1.0, 2 and 2.7%. The crusts at the end of the season were removed from the evapn. tubes after washing with a 1.5% HCl soln. and a 2.5% NaOH soln., but not from the plates. Samples taken from the 2nd unit had much Fe and only traces of Cu; those from the tubes contained much Cu. The last unit had steel tubes, and the 3 others brass; the crusts were more easily detached from the brass than from the Fe. The Cu in the crust was due to mech. detachment and to the solvent action of NH_3. R. SANSONE

Effect of sodium bisulfite upon polarizing power of sugars and the use of sodium bisulfite in sugar analysis. YOSHINORI TOMODA AND TAMIO TAGUCHI. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 434–41(1930).—$NaHSO_3$ lowers markedly the polarizing power of glucose, arabinose, galactose and lactose, and slightly that of maltose, but that of mannose, fructose, sucrose, raffinose and dextrin is practically unchanged. The rotation of glucose-bisulfite mixts. has been studied over a wide range of concns., and the results are shown in tables and graphs. At a concn. of 30 g. $NaHSO_3$ in 100 ml. the rotation of glucose becomes practically 0, being —0.5° Ventzke (V) for 10 g. glucose, and +0.8°V. for 25 g. glucose, in 100 ml. at 20° in a 200-mm. tube. The combination of glucose and bisulfite does not strictly follow the mass action law. The effect of $NaHSO_3$ may be used for the analysis of glucose-fructose mixts., such as honey and invert sugar. If x is g. glucose, and y is g. fructose in 100 ml., P the °V. of the mixed soln. at 20° in a 200-mm. tube, and P' that in the presence of 30 g. $NaHSO_3$ in 100 ml., then $x = 0.3225\ (P - P')$, and $y = 0.1859\ (-P')$. The max. error is ±6.5%. Glucose (x), and maltose (y), may be detd., with the same accuracy, in mixts. of the 2, the equations being $x = 0.3225\ (P - 1.2P')$, and $y = 0.1247\ (1.2P')$. The factor 1.2 corrects for the slight effect of $NaHSO_3$ on the rotation of maltose. The method may also be applied to hydrolyzed starch and similar products. F. W. ZERBAN

Apparatus for filtering sugar solutions or other liquids under pressure (Brit. pat. 334,663) **1**. Fertilizers [from sugar manufacture] (Fr. pat. 691,129) **15**. Purifying sugar] solutions (Fr. pat. 690,483) **13**. The storage of activated charcoal (KADLEC) **18**.

Sugar juices. RAYMOND S. DE VILLÈLE. Fr. 689,765, Dec. 27, 1929. Substances in suspension in sugar juices are pptd. by adding $(AcO)_2Pb$. The juice is filtered and submitted to the action of an elec. current, whereby the Pb is carried to the neg. electrode and is deposited there.

Presses for separating sugar juice from raw materials. ÉTABLISSEMENTS MOLLET-FONTAINE. Fr. 690,491, Feb. 24, 1930.

Refining sugar juice. ELEKTRO-OSMOSE A.-G. (GRAF SCHWERIN GES.) (Bruno Böttcher, inventor). Ger. 510,903, June 17, 1926. Sugar juice is placed between diaphragms of a neg. character and subjected to an elec. current. The liquid sepg. around the anode is electrolytically refined juice.

Drying apparatus for sugar-cane residues, especially green bagasse. HENRY W. HOLGATE. Ger. 510,684, Oct. 4, 1928.

Sucrose from impure solutions containing invert sugar. HOLGER DEF. OLIVARIUS (to Calif. Packing Corp.). U. S. 1,788,628, Jan. 13. The impure soln. is concd. to 35° to 65° Brix so as to allow subsequent fermentation of invert sugar to take place without material inversion of sucrose, and the material is then subjected to fermentation by the action of ordinary yeasts.

Carbohydrates. SCHERING-KAHLBAUM A.-G. Fr. 36,743, Mar. 18, 1929. See Ger. 486,801 (*C. A.* **24**, 1539).

29—LEATHER AND GLUE

ALLEN ROGERS

The action of oxygen on tannin. J. JANY. *Collegium* **1930**, 453–60.—Although atm. O can oxidize tannin, the absorption of O by a tan liquor was not increased by addn. of hide powder; therefore atm. O has no influence on the vegetable tanning proc-

ess. Absorption of O by tannin is the result of its phenolic character. Tannin and pyrogallol absorbed O to about the same extent, 6–7% (by wt.) per hr. from a 1% soln. at p_H 12. Below p_H 9 absorption ceased. I. D. CLARKE

Proposed directions for the filter method of quantitative tannin analysis. FRITZ STATHER. *Collegium* 1930, 480–93.—The International method for tannin analysis is not yet perfected. The shake method has been official since 1906, but a filter method has been most used in Germany, although different labs. do not agree as to details. A proposed filter method is given. Data are included showing the influence of small changes in certain details. I. D. CLARKE

Specific gravity, poured gravity and storage weight of solid tanning extracts. WILHELM VOGEL. *Ledertech. Rundschau* 22, 129–31(1930).—The sp. gr. detd. in toluene at 20° of solid quebracho, chestnut, mimosa and mangrove exts. contg. 16–20% H_2O was between 1.40 and 1.55. Powd. exts. had approx. the same sp. gr. as solid exts. except 2 quebracho (1.01–1.07) and 1 hemlock ext. (1.15). Powd. ext. poured into a 100-cc. vessel had an apparent sp. gr. of 0.40–0.77 for loose and 0.60–1.16 for packed powder. The storage space required for ext. in sacks is shown. I. D. CLARKE

Rapid liming for upper leather. V. KEILIN. *Vestnik Kozhevennoi Prom. i Torgovli* (*Vestnik of Leather Ind. and Trade*) 1930, 26–7; *Ledertech. Rundschau* 22, 118–20 (1930).—Pyrolignite of lime liquors, heated to about 31°, dehaired skins in about 4 days or half the usual time. Satisfactory leather was produced from the skins. I. D. CLARKE

Some density data on leather. IRA D. CLARKE. *Ind. Eng. Chem.* 23, 62–7 (1931).—Actual d. and apparent d. of leather strips were measured in tubes by displacement of kerosene; for actual d. while the leather was immersed in kerosene air was removed from the voids by suction. Moisture in the leather affected the results slightly, but no general correction was found. Actual d. was nearly const. regardless of the kind of skin, position in the skin or nature of the tanning and finishing process, all values were between 1.327 and 1.433. Since actual d. is nearly const., apparent d. and percentage voids are closely related, the latter vary widely for different leathers. Dry hide powder had an actual d. of 1.346 and some dry tanning exts. had an actual d. between 1.484 and 1.589. I. D. CLARKE

The fine structure of gelatin micellae. OTTO GERNGROSS, KARL HERRMANN AND WALTER ABITZ. *Biochem. Z.* 228, 409–25(1930); cf. *C. A.* 25, 231.—Gelatin is studied by means of Röntgen rays. S. MORGULIS

Condensation products of resin and phenol [in tanning] (U. S. pat. 1,788,371–2) 26.

MACHON, HUBERT: **Die Bestimmung und Bedeutung der Wasserstoffionenkonzentration (p_H) in der Gerberei.** Freiberg: Selbstverlag d. Vf. 50 pp. M. 2.50

Dehairing skins. E. LENK & F. LIPPNER (FIRM). Fr. 689,858, Feb. 13, 1930. Material for dehairing and cleaning skins is made by growing proteolytic bacteria on nutritive albumin-contg. substances such as meat or finely divided vegetable substances with the addn. of catalysts. The mixt. of bacteria, their digestive products and enzymes are dried by the addn. of indifferent substances.

Removing hair or wool from skins. HILAIRE A. BARE, MARIE J. KERREMANS and HENRI M. J. A. DE COSTER. Fr. 691,196, Mar. 5, 1930. See Belg. 368,267 (*C. A.* 25, 839).

Depilatory paste. INES PAGLIANI and MARIO A. ERCOLINI. Fr. 689,734, Feb. 11, 1930. A depilatory paste contains colophony, virgin wax and chlorophyll.

Tanning. B. P. ALEKSANDROV and A. P. ALEKSANDROV. Russ. 63,527, Feb. 1, 1930. The hide prepd. in the usual way is impregnated with chromic acid salt soln. and subjected to the action of x-rays.

Tanning agents. I. G. FARBENIND. A.-G. (Hermann Schütte, inventor). Ger. 510,445, Aug. 24, 1927. Tanning agents are prepd. by condensing phenol alcohols with resorcinol or its homologs under such mild conditions that water-sol. products are obtained. The condensation may be effected in the presence of a small quantity of acid at a temp. not above 60°. Examples are given. Cf. *C. A.* 24, 1542.

Tanning agents. I. G. FARBENIND. A.-G. (Hermann Schütte, inventor). Ger. 512,405, Apr. 1, 1928. Addn. to 510,445 (preceding abstr.). Tanning agents are prepd. by condensing resorcinol or its homologs under mild conditions with the methylol compds. obtainable by treating an aromatic hydroxycarboxylic acid with CH_2O, or reagents yielding CH_2O, in the presence of a base. Examples are given.

Tanning extracts. S. D. BALAKHOVSKII. Russ. 47,965, May 25, 1929. Phenol is added to water used in the extn. of tannin from bark.

Apparatus for treating solids with liquids particularly for tanning. VICTOR A. COLLINS. Fr. 689,831, Feb. 13, 1930.

Chromium sulfate. WYDLER & L'EPLATTENIER. Swiss 141,035, Jan. 10, 1929. Fe-free $Cr_2(SO_4)_3$ soln. usable directly for *tanning* is obtained by dissolving Cr-Fe ore in H_2SO_4 and sepg. the $FeSO_4$ by crystn.

Imitation leather. O. G. BOHLIN. Brit. 334,361, Aug. 10, 1929. Material with a rubber base and a surface more solid than the underlying material is prepd. by first subjecting the surface to cold vulcanization (as with use of S chloride or "ultra-accelerators") and then hot vulcanizing in the usual manner. Rubber and animal or vegetable fibers may be used as raw materials

Gluing veneer. B. P. ALEKSANDROV and A. P. ALEKSANDROV. Russ. 63,527, Feb. 1, 1930. Chromic acid salts are added to the glue and the finished veneer is exposed to the action of x-rays.

A method of estimating with methylene blue the adsorption power of commercial carbon blacks. Other properties of blacks. R. DITMAR AND K. H. PREUSSE. *Rubber Ind.* (London) **11**, 416-8(1931).—English version of *C. A.* **25**, 842. C. C. DAVIS

Fillers and their functions. V. Oil substitutes. F. HARRIS COTTON. *India Rubber J.* **80**, 411–3(1930); cf. *C. A.* **25**, 841. C. C. DAVIS

The manufacture of synthetic molding powders. F. A. BATH. *Rev. gén. caoutchouc* **7**, No. 66, 19-21(1930).—A review and discussion of general problems. The pressure used in molding is considered to be the most important factor in manuf. C. C. D.

The plasticizing of rubber. F. JACOBS. *Rev. gén. caoutchouc* **7**, No. 66, 9–14 (1930); cf. *C. A.* **25**, 840.—The discussion includes various French softeners and wood tars and resins. C. C. DAVIS

Behavior of antioxidants in rubber stocks containing copper. PAUL C. JONES AND DAVID CRAIG. *Ind. Eng. Chem.* **23**, 23 6(1931).—The expts. deal with the behavior of antioxidants of various types (paraffin wax, 4,4'-diaminodiphenylmethane, *N,N'*-di-*p*-tolyl 1,2-ethylenediamine, phenyl-α-naphthylamine, phenyl-β-naphthylamine, *N,N'*-diphenyl-*p*-phenylenediamine, *N,N'*-di-β-naphthyl-*p*-phenylenediamine, aldol-α-naphthylamine and tetraphenylhydrazine) in vulcanizates of different compns, each of which was cured with and without Cu stearate. The aging effects were observed by natural storage in darkness, by heating in air at 70° and by heating in O under 300 lb. per sq. in. pressure at 70°. The results show that some of the antioxidants retarded the deterioration caused by the Cu stearate. In this respect the secondary aromatic amines were by far the most effective. In general, however, it is difficult to distinguish clearly the relative effects of different antioxidants on the phys. changes during aging because of differences in the effect of the different antioxidants on the rate of vulcanization. The effects obtained with some of the antioxidants warrant their use in practice where rubber products undergo extensive oxidation as a result of the action of Cu or Cu compds., *e. g.*, when they are in contact with brass. C. C. DAVIS

Mechanical properties of rubber in compression at low temperature. W. D. DOUGLAS. *India Rubber J.* **80**, 899-901(1930).—A study of the stress-strain curves of the compression of cured rubber at 20°, 10°, 0°, —10°, —20°, —30°, —40° and —50°. The *method* and technic are described and the results are recorded graphically. The stress-strain curves include both static and dynamic deflections. C. C. DAVIS

Toxic substances in the rubber industry. XVIII. Hydrogen sulfide. P. A. DAVIS *Rubber Age* (N. Y.) **28**, 405–6(1931); cf. *C. A.* **25**, 843.—H_2S is so toxic

that it should be classed with HCN and CO, and where it is a const. factor the operations should be in a closed system and the H_2S eventually burned. The concn. in the open should be below 0.01 part per 1000. C. C. DAVIS

Rubber in the shoe industry. G. DUMONTHIER. *Rev. gén. caoutchouc* **7**, No. 66, 31–2(1930).—A general discussion with representative formulas. C. C. DAVIS

The manufacture of rubber belts. THOS. FAZAKERLEY. *Rev. gén. caoutchouc* **7**, No. 66, 15–7(1930).—A general description, with representative rubber formulas. C. C. DAVIS

Testing of railway brake and heating hose. ANSELM TALALAY. *India Rubber J* **81**, 21–2(1931).—The specifications of the German State Railways are described and illustrated. C. C. DAVIS

Flax versus cotton in tire fabric construction. H. WALTER GROTE. *Rubber Age* (N. Y.) **28**, 355–6(1931).—A new process for defibration of flax fiber may make linen a substitute for cotton fabric in tires. C. C. DAVIS

Accelerators of vulcanization. F. JACOBS. *Caoutchouc & gutta-percha* **27**, 15258–62 (1930); cf. *C. A.* **25**, 233.—The accelerators include certain amines and guanidines. C. C. DAVIS

Modern accelerators and their capabilities. F. HARRIS COTTON. *India Rubber J.* **80**, 481–2, 605–7(1930). A review and discussion. C. C. DAVIS

Vulcanization accelerators. A survey of the patent literature of the last few years. VI. ALADIN. *Gummi-Ztg.* **45**, 153(1930); cf. *C. A.* **25**, 233.—The tabulated data and information are concluded with a total of 227 accelerators. C. C. DAVIS

The adsorption theory of the combination of sulfur during vulcanization. WOLFGANG OSTWALD. *Gummi-Ztg.* **44**, 1743(1930).—A criticism of certain features of a book by Kindscher (*Handbuch der Kautschukwissenschaft*). C. C. DAVIS

The adsorption theory of the combination of sulfur during vulcanization. HEINRICH LOEWEN. *Gummi-Ztg* **45**, 622(1931).—Comments on a paper by Ostwald (cf. preceding abstr.). C. C. DAVIS

Hot vulcanization. PAUL BREDEMANN. *Gummi-Ztg.* **45**, 502–3(1930); cf. *C. A.* **25**, 843. C. C. DAVIS

Studies of the conditions affecting the vulcanization of rubber. V. The effect of accelerators on the heat of vulcanization. Y. TOYABE. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 275–6(1930); cf. *C. A.* **24**, 3397.—The heats of vulcanization of rubber mixts. contg. different proportions of S and 10 different accelerators, resp., were measured by means of a differential thermocouple. The course of the curves was similar to that of the curves with unaccelerated mixts., but the temp. maxima occurred sooner with the accelerated than with the unaccelerated mixts. The expts. show that these accelerators promote the disaggregation of micellar structure of rubber, as shown in the previous expts. (cf. T., Fukunaga and Fukuda, *C. A.* **24**, 4664; T. and Fukunaga *C. A.* **24**, 4664) before the chem. combination of rubber and S. By reducing the size of the individual rubber micelle, they increase the no. of chem. units of rubber entering the reaction with S, *i. e.*, the probability of combination of the two becomes greater. The time at which the temp. maxima appear in the expts., which is shortened by accelerators, shows that this theory holds good if it is considered that the temp. maxima correspond to the disaggregation maxima of the rubber hydrocarbon in question. C. C. D.

Imitation leather (Brit. pat. 334,361) **29.**

BARY, PAUL: **La régénération des caoutchoucs.** Paris: l'Edition technique. 145 pp.

SEIDEN, RUDOLF: **König Kautschuk. Kautschuk in Wissenschaft, Wirtschaft und Technik.** 4th ed. Stuttgart: Dieck & Co. 80 pp. M. 1.80; bound, M. 2.80

Rubber. I. G. FARBENIND. A.-G. Fr. 689,128, Jan. 30, 1929. The aging of natural or artificial rubber is prevented by adding indanphenols which have, *e. g.*, the formula $C_6H_4.CH_2.CH_2.CHR$, in which R is an aromatic group substituted by at least one OH group, and all the groups may contain univalent substituents (cf. *e. g.*, Fr. 636,606).

Rubber. I. G. FARBENIND. A.-G. Fr. 690,043, Feb. 15, 1930. Lampblack is introduced into rubber or the polymerization products prepd. from butadiene hydrocarbons or their derivs., by making a mixt. of lampblack and a liquid product obtained

by incomplete polymerization of a hydrocarbon or hydrocarbon deriv. and incorporating the mixt. with the rubber, etc.

Rubber. I. G. FARBENIND. A.-G. Fr. 690,453, Feb. 22, 1930. Tars obtained from the controlled carbonization of lignites, etc., and deprived of their volatile fractions by distn. are used as fillers for natural or synthetic rubber instead of lampblack. The residue from the distn. may be extd. with acetone or other compds. before use.

Rubber from latex. ALFRED ZANGGER. Fr. 689,424, Feb. 4, 1930. Rubber is extd. from latex of plants growing in the temperate zone and trees other than those called rubber trees by the action of CCl_4.

Rubber deposition by electrophoresis, etc. DUNLOP RUBBER CO., LTD., R. G JAMES and D. F. TWISS. Brit. 334,581, June 6, 1929. In the electrophoretic deposition of materials such as rubber from a dispersion the particles of which normally carry a neg. charge, the H-ion concn. is increased in the presence of formaldehyde to effect reversal of the charge on the particles without causing coagulation; deposition is then effected on the cathode or a porous or semipermeable mold surrounding it. Various details, examples and modifications of procedure are described.

Electrophoretic deposition of rubber. THE ANODE RUBBER CO., LTD. Ger. 512,170, Sept. 5, 1925. This corresponds to Brit. 257,885 (*C. A.* **21**, 3141), but gives specific examples.

Treating rubber. DEUTSCHE HYDRIERWERKE A.-G. Fr. 689,541, Feb. 7, 1930. Ales. of high mol. wt. such as dodecylic or octadecylic ales. are used as accelerators or protectors against aging in the treatment of rubber.

Preserving rubber from aging. ALBERT M. CLIFFORD (to Goodyear Tire & Rubber Co.). U. S. 1,788,860, Jan. 13. Small proportions of substances such as α-amino-β-naphthol or α chloro-β-naphthol (suitably about 1%) are added to rubber compns.

Preserving rubber against aging. WM. D. WOLFE (to Goodyear Tire & Rubber Co.). U. S. 1,788,903, Jan. 13. Amino-*p*-hydroxydiphenyl (suitably about 1%) is used as an antioxidant or age-retarder, and may be prepd. (by a process details of which are given) from *p*-hydroxydiphenyl by nitration and subsequent reduction.

Rubber compositions. JACQUES DELPECH. Fr. 689,445, Feb. 5, 1930. Rubber is made non-slippy by the addn. of powd. leather, cotton, wool, etc.

Rubber composition with linseed oil. EUGENE E. AYRES, JR. (to B. A. S. Co.). U. S. 1,789,062, Jan. 13. An aq. dispersion of rubber is emulsified with linseed oil, heated with agitation, and air is blown through the material. A product is thus obtained which is suitable for waterproofing, elec. insulation, floor covering, paint and varnish manuf., etc.

Coloring rubber. IMPERIAL CHEMICAL INDUSTRIES, LTD., A. J. HAILWOOD, W. J. S NAUNTON, A. STEWART and A. SHEPHERDSON. Brit. 334,688, Aug. 15, 1929. The pigments used for coloring rubber as described in Brit. 304,376 (*C. A.* **23**, 4848) are prepd. by coating the filler with the vat dye by oxidizing an alk. soln. or suspension of the leuco compd. of the vat dye in the presence of the filler (such as $MgCO_3$), the latter being treated (before or after incorporation of the dye) with a soap. The use of soap produces pigments giving brighter shades than those prepd. without soap.

Recovery of rubber. CAOUTCHOUC RÉCUPÉRÉ RÉNO. Fr. 689,904, April 22, 1929. Rubber and textile fibers in used tires, etc., are sepd. and recovered in 2 stages: in the first the waste rubber is soaked and made to swell by oil obtained by the dry distn. of waste rubber, and in the 2nd the textiles and rubber are sepd. by mech. operations. The rubber is preferably regenerated by treatment with NaOH.

Rubber articles. SOCIETÀ ITALIANA PIRELLI and UGO PESTALOZZA. Fr. 36,738, Mar. 7, 1929. Addn. to 651,684 (*C. A.* **23**, 3509). In making rubber articles by local heating according to Fr. 651,684, a di-substituted aromatic compd. of guanidine such as *sym*-diphenylguanidine, *sym*-phenyl-*o*-tolylguanidine or *sym*-di-*o*-tolylguanidine is added to the latex before heating.

Apparatus for "plasticating" rubber (comprising feeding screws and an extrusion nozzle, etc.). W. A. GORDON (to Farrell-Birmingham Co.). Brit. 334,509, April 23, 1929. Structural features.

Covering fabric with rubber. V. D. OTSING. Russ. 34,708, Nov. 1, 1928. The fabric is first impregnated with a sol. Mg salt and then treated with NH_4OH to ppt. MgO on the fabric. The dried fabric is treated with rubber by the usual methods.

Cords for use in vehicle tire manufacture. WALLACE H. PAULL and REGINALD TRUESDALE (to Dunlop Tire and Rubber Corp. of America). U. S. 1,788,439, Jan. 13. Fibrous ramie and artificial silk are used together.

Corrugated rubber tubing covered with twill of similar material. DUNLOP RUBBER

Co., LTD., and F. W. WARREN. Brit. 334,440, Nov. 1, 1929. Various details of manuf. are described.

Paints for rubber tires, shoe soles, etc. W. E. FRITH. Brit. 334,693, Aug. 23, 1929. Celluloid paint mixed with fine sand is applied to provide a non-slipping surface, and to preserve and waterproof the material.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 334,184, May 25, 1929; Fr. 688,790, Jan. 24, 1930. A diolefin such as butadiene is polymerized in the presence of alkali or alk. earth metals (such as Na wire or Na dust) and in the presence of a cyclic di-ether such as dioxane or its derivs. to facilitate polymerization (suitably at a temp. of 40–65° in a rotary autoclave). Solvents or diluents such as benzene, gasoline or ether also may be present. Cf. *C. A.* **25**, 845.

Synthetic rubber. I. G. FARBENIND. A.-G. Fr. 689,070, Jan. 29, 1930. Synthetic substances of the nature of rubber are improved by a treatment with org. nitro compds such as $PhNO_2$, $C_6H_4(NO_2)_2$, dinitronaphthalene and $C_6H_3(NO_2)_3$. Several examples are given, the rubber compd. being heated with the nitro compd. in soln. in an org. solvent.

Synthetic rubber. I. G. FARBENIND. A.-G. Fr. 689,404, Feb. 4, 1930. Synthetic rubber, particularly suitable for vehicle tires, is made by polymerizing mixts. of dimethylbutadiene with other butadiene hydrocarbons such as butadiene or isoprene or a mixt. of butadiene and isoprene

Synthetic rubber compositions. I. G FARBENIND. A.-G. Brit. 334,554, June 5, 1929. Finely divided C is added to mixed hydrocarbon-artificial rubber products such as mixts. of polymers of butadiene and of 1,3- or 2,3-dimethylbutadiene, mixts of "heat" butadiene rubber and "emulsion" butadiene rubber or mixts. of butadiene-Na rubber and isoprene "emulsion" rubber.

Rubber-like mass. GOSUDARSTVENNOYE VSESOYUZNOYE OB'EDINENIE BUMAZHNOI PROMUISGLENNOSTI. Russ. 11,305, Oct. 11, 1926. Fungi belonging to the types Polyporaceae or Agaricaceae are dried, disintegrated to a fine powder, and agitated with turpentine, acetone, ether and similar org solvents until a uniform consistency is reached. The mass is passed through rollers or other app. used in the rubber and paper industries and then formed into the desired shape

Artificial materials. I. G. FARBENIND A.-G. Fr. 690,484, Feb. 24, 1930. Artificial materials of all sorts are made from derivs. of polymerization products not distillable without decompn of butadiene hydrocarbons. The derivs. are prepd. by introducing by addn. or substitution, elements or uni- or multi-valent groups. Thus, when butadiene hydrocarbons are polymerized with Na, the Na may be replaced by COOH by treatment with CO_2. Examples are given.

Artificial materials. I. G. FARBENIND. A.-G. Fr. 691,357, Nov. 21, 1929. Artificial materials are made by heat treatment of the polymerization products of butadiene hydrocarbons in a finely divided state, and in a form capable of being hardened. Other substances capable of being hardened may be added.

Rubber vulcanization accelerator. HOWARD W. MATHESON (to Canadian Electro Products Co.). U. S. 1,788,773, Jan. 13. An accelerator is produced by condensing acetaldehyde and the fractions b. 200–275° from the distn. of a product resulting from the passage of C_2H_2 into aniline at a temp. of 60–120° in the presence of a catalyst such as Cu_2Cl_2. Cf. *C. A.* **24**, 752.

Composition for use as an accelerator in the vulcanization of rubber. CLAYTON O. NORTH (to Rubber Service Laboratories Co.). U. S. 1,787,258, Dec. 30. A product is formed by combining the reaction product of substantially 3 mol. proportions of butyl aldehyde and 1 mol. proportion of aniline, the reaction product of substantially 3 mol proportions of AcH and substantially 2 mol. proportions of aniline, creosote oil and pine oil. Cf. *C. A.* **25**, 618

Vulcanizing agent for rubber. HENRY C. L. DUNKER. Ger. 510,837. Mar. 20, 1928. Se is used as the vulcanizing agent in the manuf. of rubber shoes.

Apparatus for vulcanizing rubber tires. J. FERGUSON & SONS, LTD., and A. S WELCH. Brit. 334,601, June 7, 1929. Structural features.

Vulcanizing rubber tires, etc. INDUSTRIAL PROCESS CORP. Brit. 334,695, Nov. 26, 1928. In a process for vulcanizing products such as tires in which mixed gases are employed as the heating medium in a gas bag (as described in Brit. 205,577 (*C. A.* **23**, 4756)), the gas bag is brought to a desired temp. before each operation, to ensure uniformity of treatment. Cf. *C. A.* **24**, 4426.

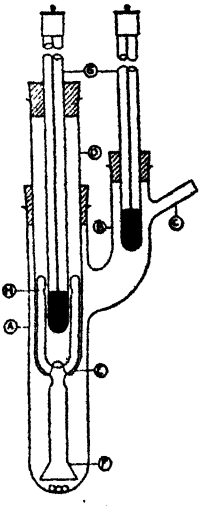
CHEMICAL ABSTRACTS

Vol. 25. MARCH 20, 1931 No. 6

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

A molecular velocity filter. JOHN A. ELDRIDGE. *Proc. Iowa Acad. Sci.* **36**, 307 (1929).—A method has previously been described by which the velocity of mols. could be measured. A qual. combination of Maxwell's distribution law was obtained. A filter is being constructed which will have much greater resolving power and also greater sensitivity. W. G. GAESSLER



Apparatus for hot filtration of saturated solutions. S. H. BERTRAM AND W. A. VAN MEURS. *Chem. Weekblad* **27**, 7–8(1930).—A simple app. for filtering satd. solns. in volatile solvents, in which the filter is heated by means of the vapor of the solvent, is described. B. C. A.

Theoretical research concerning the settling of dust from streaming air and its application to the theory of the dust filter. FRITZ ALBRECHT. *Physik. Z.* **32**, 48–56 (1931). W. E. VAUGHAN

Filtrations. C. A. GUIDINI. *Schweiz. Apoth. Ztg.* **68**, 283–4(1930).—For effective filtering, *Seitz filters*, in which finely divided and purified fibrous asbestos is used, are recommended. S. WALDBOTT

An adjustable drop-control for burets. FRANKLIN HOLLANDER. *Science* **73**, 45–6 (1931).—A clamp on the sleeve of the stopcock carries an adjustable pin. A rod, set to strike the pin when the flow just begins, is attached to the handle of the plug, and by adjusting the pin the rate of flow is regulated. J. H. MOORE

Molecular-weight apparatus for the boiling-point method. EDWARD M. HOSHALL. *J. Chem. Education* **8**, 353–4(1931).—In the Pyrex assembly (see diagram) a modified Cottrell pump, *F*, discharges the boiling soln. over the bulb of one Beckman thermometer, *G*. The other thermometer, in *B*, indicates the temp. of pure solvent. *F* should be short for a low-boiling system. B. A. SOULE

A new micro melting-point apparatus. LUDWIG KOFLER AND HANS HILBCK. *Mikrochemie* **3**, 38–44(1931).—The instrument furnished by C. Reichert of Vienna gave fairly good results at low temps., but erroneous readings were obtained when the m. p. was above 150°. After considerable experimentation a new instrument was prepd., for the prepn. of which detailed directions are given. Results with various org. substances show that the new, electrically heated instrument will give results within 1° when the m. p. is below 200° and within 2° when the m. p. lies between 200° and 300°. The m. p. is observed under the microscope with magnification up to 135 diams. W. T. H.

New microbalance. JULIUS DONAU. *Mikrochemie* **3**, 1–14 (1931).—A balance is described which overcomes most of the difficulties encountered with the Nernst microbalance. Directions for making, setting up and adjusting the balance are given, and a series of weighings shows that the results obtained are comparable in accuracy with those obtained with an ordinary balance and much larger quantities of material. The original paper must be consulted for details. W. T. H.

The polarimeter H.P.2 of the firm of Dr. Steeg & Reuter, Bad Homburg. K. SEILER. *Schweiz. Apoth. Ztg.* **68**, 493–5(1930); cf. *C. A.* **24**, 4667.—A 10-cm., an 18.94-cm. or a 20-cm. tube and white or Na light may be used in the app. For white light, the easily measurable concns. of dextrose solns. are between 5 and 10% by vol., although S. in using the 18.94-cm. tube and white light was able to det. 25% of dextrose to within 0.350%, 15 to 0.15%, etc. The deviations were about equal to those observed with other app. Detns. in Na light, however, gave excellent results for

dextrose contents of 1, 5, 10, 15, 25 and 50%, the abs. max. deviation being only 0.035%. The instrument (No. 1739) fully conforms to the requirements of urine analysis and of detns. demanded by the forthcoming Pharm. Helv. V. S. WALDBOTT

The Zeiss circular polarimeter. K. SEILER. *Schweiz. Apoth. Ztg.* **68**, 629–31 (1930); cf. preceding abstr.—The advantages of this app. are: The stand supports the (horizontal) polarimeter tube at its end; opposite to it, also attached to the stand at a definite distance, is the lighting device for white (a 15-Watt Osram lamp) or Na light. For the latter, a flat Bunsen flame touches a square salt plate, producing a uniform and lasting yellow light. By means of magnifying glasses laterally attached to the eye piece, the vernier may be read to an exactness of 0.05°. The 3-sectioned field of vision (cf. *C. A.* **24**, 4667) is very clear, permitting exact observation of color changes. With this app. only 5 to 10% of dextrose may be detd. in white light, but these results, also those with 1–50% of dextrose detd. in Na light, are very exact. S. WALDBOTT

Improved apparatus for growth of metal crystals. A. G. HOYEM. *Proc. Iowa Acad. Sci.* **36**, 301(1929); cf. *C. A.* **23**, 2862.—The availability of a small quantity of exceedingly pure Zn has made it necessary to design app. of such a nature that a series of crystals may be grown with predetd. orientations, distributed at intervals of several degrees from 0° to 90°, and without oxidation or waste of the material. W. G. G

A new simplified apparatus for exact gas analysis of gas mixtures of 3–4 cc. or more. ALBERT SCHMIDT. *Gas u. Wasserfach* **73**, 1137–44(1930).—The Reichanstalt has developed a new const.-vol. gas-analysis app., the change in pressure due to absorption of gas constituents being read on a manometer. The absorption pipet is of simple construction and is also used as the slow combustion pipet (Pt wire). The smallest usable quantities of absorbents are introduced into the absorption pipet during the analysis, the effect of gas soly. in large vols. of absorbent being thus avoided. A sep. pipet is provided for fuming H_2SO_4. When using 3–5 cc. gas, the errors in measurement are ±0.05%, and with 30–80 cc. gas ±0.01%. Methods of procedure for typical gases and calcn. of results are given. Changes in temp. or pressure may be reduced to negligible amts. but may be compensated for in calcns. Const.-volume gas measurements are more accurate than const.-pressure measurements. R. W. RYAN

Heat conductivity instruments for gas analysis. C. A. ROBAK. *Tek. Ukeblad* 76, 249–51(1929).—A review. C. A. ROBAK

New analytical balance with air-damping and milligram projection. LUDWIG KÖHLER. *Chem.-Ztg.* **54**, 977(1930).—Ströhlein and Co.'s rapid balance "Rekord" is described. J. H. MOORE

A new apparatus for rapid determinations of nitrogen in series by the Kjeldahl method. K. SCHARRER. *Tierernährung* **2**, 376–80(1930).—A description and illustration of a macro app. for N detn. in *forage* analogous to the micro method of Pregl. Results are excellent, and a no. of analyses in series can be run in a very short time and with a saving of material. J. C. JURRJENS

New electrode vessels for rapid p_H determinations. W. KORDATZKI. *Chem. Fabrik* 1931, 25–7.—Descriptions, with 7 cuts, of app. for measurements with the Pt-H_2 and Pt-quinhydrone electrodes against the satd. KCl-Hg_2Cl_2 electrode. A porous diaphragm seps. the electrolytes. Results are tabulated. J. H. MOORE

Simple apparatus for fluorescence microscopy and for fluorescence photomicrography. P. METZNER. *Mikrochemie* **3**, 72–91(1931).—A simple arrangement is shown suitable for the study of fluorescence under the microscope with reflected light; a parabolic mirror is used for the illumination. The arrangement is suitable, particularly when a quartz lamp is used as source of light, for taking photographs of fluorescent bodies placed under the microscope. The technic for carrying out the work is described in detail, and the method is illustrated with 18 pictures obtained by the described procedure. A bibliography is appended. W. T. H

Ionometer system of P. V. Golovin. P. V. GOLOVIN AND T. N. PATER. *Zhurnal Sakharnoi Prom.* **4**, 274–7(1930).—A newly invented potentiometer is described by which p_H detns. can be made without any calcns. V. E. B.

Bisulfate fusion. S. R. SCHOLES. *Glass Ind.* **11**, 237(1930).—A small Erlenmeyer flask of Pyrex glass is more satisfactory than a Pt crucible for $NaHSO_4$ or $KHSO_4$ fusions, since it is sufficiently refractory and more resistant to corrosion, and the operations of soln. and transfer are avoided or simplified. H. F. K.

Colloid mills. AUGUST CHWALA. *Kolloid-Z.* **54**, 117–23(1931).—A review of German patents. A. FLEISCHER

High-speed dispersion machines. A contribution to [the history of] their development and mode of operation. H. GROHN. *Chem. Fabrik* **1931**, 1–4, 13–5, 27–8; cf.

C. A. **24,** 5186.—After a review of the older theories those based on recent investigations are discussed, such as: the disadvantages of the excentric placing of the beaters in the housing, the significance of the relative speed of the beaters and the material over the beater-plates, and the advantages of more beater-plates. The advantages of the Vacuumtrockner (successor to E. Passburg Co.) mill over the Plauson and the Oderberger mills are summarized. J. H. MOORE

Apparatus for measuring the surface tension of liquids. MARCEL CHOPIN. *Compt. rend.* **191,** 1293–5(1930).—The app. described (with 1 cut) depends on the adhesion between the surfaces of 2 cylinders moistened with the liquid. With a cylinder 40 cm. diam. a detn. can be made with 0.3 cc. of liquid; with 120 cm. diam. fair results can be obtained with 0.15 cc. liquid. J. H. MOORE

A new fire-damp detector. ROMAN MOGILNICKIJ. *Montan. Rundschau* **23,** 10–4 (1931).—A detailed description is given of a portable app. with which CH_4 up to 5% can be detd. accurately in about 90 sec. by passing over a hot Pt spiral and reading the change in height of a water column. J. H. MOORE

Note on a simple one-piece electrodialysis apparatus. L. REINER. *J. Phys. Chem.* **35,** 423–4(1931).—The app. described by R. (*C. A.* **21,** 2588) has been improved by fusing in 2 Jena-glass filter plates as supports for the collodion membranes. J. H. MOORE

Low-vacuum pressure-control apparatus. L. A. RICHARDS. *Rev. Sci. Instruments* **2,** 49–52(1931).—The app. is easily constructed and gives dependable and accurate pressure regulation down to a few mm. Hg. With only 1 pump the pressure may be controlled in any no. of tanks independently. J. H. MOORE

Unfired pressure vessels. W. SPRAGEN. *Ind. Eng. Chem.* **23,** 220–6(1931).—A general discussion of the design of unfired pressure vessels to be fabricated by fusion welding with brief notes on material, methods of welding, inspection, testing and application of the Kinzel-Miller formula for safe working stress. A. W. HOLMES

Purification of mercury. ERLING BOTOLFSEN. *Teknisk Ukeblad* **76,** 314–5 (1929). A continuous *lab. app.* is described with illustration. C. A. ROBAK

An experimental study of the absolute temperature scale. I. The construction of several types of platinum resistance thermometers. JAMES A. BEATTIE, DAVID D. JACOBUS AND JOHN M. GAINES, JR. *Proc. Am. Acad. Arts Sci.* **66,** 167–84(1930).—The authors have described in min. detail and illustrated by diagrams and photographs from the construction of templets for drilling and notching the mica to the assembly of the parts, the construction of 25 ohm Pt resistance thermometers (using 175 cm. of 0.1 mm. wire for each) of the mica cross, calorimetric and strain-free types. A commutator for connecting any no. of potential-type terminal thermometers to a Mueller bridge (cf. *C. A.* **11,** 1) is also described. E. R. SCHIERZ

Electric furnace for micro-elementary analysis by the method of F. Pregl. BONIFAZ FLASCHENTRÄGER. *Mikrochemie* **3,** 15–9(1931).—The combustion furnace described by P. in 1928 has been simplified; it can be obtained from W. C. Heraus in Hanau, a. M. W. T. H.

Packing for autoclaves, etc. (Ger. pat. 511,761) **18.** Graphical treatment of the thermodynamics of the rectifying column (KEESOM) **2.**

Official Directory of the British Chemical Plant Manufacturers' Association, 1931. London: The British Chemical Plant Manufacturers' Assoc. 152 pp.

Air filter. CHESTER P. HEGAN (to American Air Filter Co.). U. S. 1,789,931, Jan. 20.

Gas filter (plate type). AMERICAN AIR FILTER CO., INC. Ger. 514,011, Nov. 23, 1927. See Brit. 288,992 (*C. A.* **23,** 550).

Rotating drum filter. EDWARD W. WOLFE-KEENE. Fr. 691,595, Mar. 8, 1930. Constructional features are described.

Suction-cell rotary filter. MASCHINENFABRIK BUCKAU R. WOLF A.-G. Ger. 511,944, May 9, 1928.

Filtering apparatus using paper pulp. SOC. DES ÉTABLISSEMENTS DAUBRON. Fr. 692,438, June 17, 1929.

Filter (with a ribbon-like filtering element) suitable for filtering engine oil. SUMNER WILTSE. U. S. 1,790,036, Jan. 27. Structural features.

Filter-press (with an inspection chamber through which the filtered liquid passes). ALLIANCE ARTIFICIAL SILK, LTD., W. H. YATES and J. A. BLACK. Brit. 335,191, June 13, 1929.

Apparatus for screening and filtering materials such as sewage or pulp mill or canning factory effluents. CHARLES T. CABRERA (to Electro Dialyzer Corp.). U. S. 1,789,425, Jan. 20. Structural features.

Cleaning device for filters with granular filtering material. THE CYCLE CO. Ger. 509,932, Mar. 27, 1925. Details are given.

Apparatus for separating oil, etc., and water. KOM.-GES. ROSENTHAL & CO. Ger. 511,367, Feb. 6, 1929.

Cooling and dust-separating apparatus for hot gases. A. HOLTER. Norw. 45,518, Sept. 3, 1928. The gases are introduced in tangential, and let out in axial direction in a drum, the walls of which are sprayed with water.

Settling device for separating dust from gases. EMIL WURMBACH and PAUL WURMBACH. Ger. 513,289, Feb. 20, 1929.

Settling apparatus for separating dust from gases. DEUTSCHE ERDÖL-A.-G. Ger. 497,315, Dec. 24, 1925.

Optical apparatus for estimating dust in gases. "DELBAG" DEUTSCHE LUFTFILTER-BAUGES M. B. H. Ger. 514,208, July 12, 1928.

Centrifugal gas cleaner. MORITZ VOIT. Ger. 514,169, Feb. 22, 1928.

Emulsifying centrifuge. RAMESOHL & SCHMIDT A.-G. Ger. 514,170, May 4, 1929.

Centrifugal apparatus for dewatering finely granular materials. LUDWIG ALIPETER. Ger. 511,300, Aug. 20, 1927

Centrifugal pump for pulpy masses. KRISTOFFER MÖRCH. Norw. 45,603, Sept 24, 1928. Air accumulating in the pump is let out through a channel through the propulsive shaft.

Machine for the forming of soft soap and other materials of a similar consistency into pieces of fixed weight and shape. BIRGER JAEGER. Norw. 47,052, Oct. 14, 1929

Laboratory distilling column. SOC. DES PRODUITS CHIM. DE CLAMECY and ERNEST CHARLES. Fr. 691,521, May 30, 1929. A laboratory distg. column consists of a glass tube in which rings are piled one above the other and between the rings bubbling plates are placed. The vapors are condensed by an ordinary condenser and part of the condensate may be returned to the column.

Baffle plate column suitable for distilling or scrubbing operations, etc. CLAUDE B SCHNEIBLE (to C. B. Schneible, K. F. Schrier and B. B. Schneider, trustees). U. S 1,790,596, Jan. 27.

Weighing dish. N. GERBER'S CO. M. B. H. Ger. 513,318, Aug. 12, 1927. The dish is made of glass and has an attached shank which is ground until the wt. of the dish is that of a given tare. The dish is intended particularly for a series of butyrometric detns. of fat in cream, etc.

High-frequency crucible. HERAEUS VACUUMSCHMELZE A.-G. Ger. 512,819, Aug 9, 1927. Details of construction without using Fe are described.

Electric recording calorimeter. HEINRICH BRINKMANN. Ger. 513,151, Feb. 19, 1926.

Liquids for hydraulic apparatus. I. G. FARBENIND. A.-G. Ger. 513,482, Nov. 15, 1928. Glycols or polyglycols or their ethers or mixts. of these, with or without water and (or) polyalcs., are used with the addn. of a wetting agent, *e. g.*, Turkey-red oil or an alkylaryl sulfonate.

Nephelometer. ERNST LEITZ G. M B. H. Ger. 513,490, June 9, 1929.

Viscometer. ERWIN MADELUNG. Ger. 513,493, Aug. 29, 1929. The detn is based on the speed of rise or fall of a test piece enclosed in a small horizontal tube contg the liquid, means being provided for inclining the tube to a predetd. extent. The tube is rotated, to keep the test piece away from the wall.

Thermometer. O. T. CLORIUS Brit. 335,410, Oct. 22, 1928. Structural features

Means for controlling high temperatures, particularly for annealing. AUGUSTE KURPJUHN. Fr. 690,825, Feb. 28, 1930.

Throttling steam-calorimeter. ERWIN H. HAMILTON. U. S. 1,789,705, Jan 20

Centrifugal steam purifying device. CHARLES G. HAWLEY (to Centrifix Corp.). U. S. 1,790,305, Jan. 27. Structural features are given of a device suitable for sepn of liquid and solid particles.

Spray apparatus for cooling salt solutions. PAUL H. MÜLLER. Ger. 511,115, Jan. 24, 1926. Spray nozzles of rubber or other elastic, heat-insulating material are used

Apparatus for obtaining large crystals by cooling salt solution under vacuum. SOC. ANON. DES ATELIERS DE CONSTRUCTIONS MÉCANIQUES ESCHER WYSS & CIE. Fr. 691,794, Mar. 12, 1930.

Apparatus for indicating the condition of a vapor. SCHÄFFER & BUDENBERG G. M.

B. H. Ger. 513,063, May 9, 1929. The app. includes a manometer and a thermometer connected to a common indicator.

Apparatus for cutting glass tubing into lengths by the action of a flame. JOHNSEN & JÖRGENSEN FLINT GLASS, LTD. and E. ASHFORD. Brit. 335,249, June 20, 1929. Various structural details are described.

Hydraulic machine for testing tensile strength, bending and compression resistance of materials. A. J. AMSLER. Brit. 335,253, June 21, 1929. Structural features.

Electric discharge lamp. N.-V. PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 334,998, July 15, 1929. Various details are described of a device with a gas-filled column, suitable for use with a. c. of 3 or more phases and which may have 3 anodes of Mo or graphite mounted in sep. chambers leading to a common channel in which may be mounted an electron-emitting electrode such as W or an alloy of Th with W or Mo or a Wehnelt cathode.

Electrode for discharge tubes. FRED HOTCHNER. U. S. 1,789,901, Jan. 20. Structural features.

Cathodes for discharge tubes. VEREINIGTE GLÜHLAMPEN UND ELECTRIZITÄTS A.-G. Austrian 119,779, July 15, 1929. In the manuf. of cathodes comprising a core wire coated with an alk. earth oxide, the core is first coated with an oxide, sulfide, or halide of a difficultly fusible metal, *e. g.*, Mo or W, not alloyable with the alk. earth metal. This may be done by treating the core with a soln. of NH_4 tungstate, thiotungstate, molybdate, etc., and then heating. The coated core is then treated with the vapor of an alk. earth metal, which reacts with the coating, and the product is finally heated to a high temp. Cf. *C. A.* **24**, 2645.

Glowing-cathode Röntgen-ray tube. C. H. F. MÜLLER A.-G. (Wilhelm Daumann, inventor) Ger. 511,565, May 31, 1925.

Device for determining the strength of Röntgen rays. C. H. F. MÜLLER A.-G. Ger. 512,652, Feb. 27, 1930.

Gas washer. THE BARTLETT HAYWARD CO. Ger. 512,826, Dec. 6, 1928.

Centrifugal apparatus for washing and cleaning gases. FIRMA EDUARD THEISEN. Ger. 513,288, Aug. 8, 1929.

Rotating mechanical washer for reaction gases. I. G. FARBENIND. A.-G. (Karl-Heinz Gebhardt, inventor). Ger. 507,790, July 13, 1927.

Apparatus for gas purification. HENRY HAEGLER. Ger. 511,984, Feb. 22, 1925. A tube filter for removing dust, etc., is described.

Apparatus for catalytic gas reactions. COMPAGNIE INTERNATIONALE POUR LA FABRICATION DES ESSENCES ET PÉTROLES. Fr. 692,080, May 27, 1929. Reaction chambers and purification chambers for catalytic gas reactions are joined together in such a way that the chambers fulfil the part alternatively of a reaction chamber, of a purification chamber in a period of activity and then of a purification chamber in a period of regeneration.

Apparatus for catalytic gas reactions. HOLZVERKOHLUNGS-INDUSTRIE A.-G. Brit. 333,111, Nov. 28, 1928. Various details are described of an app. with narrow catalyst chambers having parallel walls and which may be connected in series, parallel, or series parallel, in any suitable order. Cf. *C. A.* **24**, 4562.

Apparatus for measuring the ion content of an ionized gas stream. INSTITUT FÜR PHYSIKALISCHE GRUNDLAGEN DER MEDIZIN. Ger. 513,134, Mar. 8, 1928.

Device for estimating the combustible gas in gas mixtures. SIEMENS & HALSKE A.-G. (Heinz Gruss, inventor). Ger. 508,826, Dec. 11, 1926. The gas mixt. is burned by catalyzers under elec. heating. The method is specially applicable to flue gases.

Gas-pressure regulator. ALLGEMEINE VERGASUNGS-GES. M. B. H. Ger. 511,312, Mar. 28, 1930. Addn. to 272,920 and 456,564.

Manometer for gas analysis apparatus, etc. CHARLES B. FRANCIS. U. S. 1,790,044, Jan. 27.

Apparatus for removing oil and water vapor from gases such as air by condensation. CLYDE C. FARMER (to Westinghouse Air Brake Co.). U. S. 1,790,205, Jan. 27. An automatic regulator is provided for varying the temp. of the app. to melt congealed condensate in accord with accumulation of the latter. Various structural features are described.

Apparatus for effecting reactions between gases and solids. SULPHUR & SMELTING CORP. Fr. 690,667, Feb. 25, 1930. An app. for carrying out reactions such as the chlorination of Fe ores consists of a vessel contg. pebbles, relatively displaceable, between which the solid is fed.

Valve for pipe conduits for gases or liquids. EINAR KINDEM and A. WATZINGER.

Norw. 45,489, Aug. 20, 1928. The working body consists of a wire spiral, the threads of which lie close to each other in the tight position of the valve.

Device for saturating liquids with gases e. g., water with carbon dioxide. MAX GUGGENBÜHL. Ger. 512,628, July 3, 1927.

Apparatus for saturating liquids with gases, particularly for making beverages. MAX GUGGENBÜHL. Ger. 513,265, July 3, 1927.

Apparatus for mixing liquids. ROBINSON BROTHERS, LTD., and WM. BUTLER & CO. Ger. 511,642, July 16, 1929. The app., especially for mixing bituminous and oily liquids, is described.

Apparatus for continuously mixing or emulsifying liquids. PAUL L. A. THIBERGE Ger. 513,023, May 28, 1929 See Brit. 312,649 (*C. A.* **24**, 758).

Rotary-vane apparatus for mixing liquids with soluble substances. MASCHINENFABRIK-AUGSBURG-NÜRNBERG A.-G. Ger. 513,360, Feb. 21, 1930.

Device for the analysis of volatile liquids. SOC. ANON. DES CHARBONS ACTIFS ET PROCÉDÉS EDOUARD URBAIN. Ger. 509,849, May 18, 1929. The absorption spectra of the vapor produced by elec. heating are studied.

Device for determining the viscosity of liquids. JENÖ TAUSZ. Ger 512,835, July 14, 1928.

Apparatus for drying atomized liquids by hot gases. A.-G. NIRO. Ger. 512,795, July 18, 1926.

Instrument for measuring the turbidity, color, etc., of liquids. WM. G. EXTON Ger. 513,489, Jan. 27, 1929. See Brit. 328,556 (*C. A.* **24**, 5187).

Furnace. WILHELM SCHUH and HERMANN CUNZ. Ger. 511,661, Mar. 22, 1928 Details are given of a stepped grate for the direct introduction of air to the fuel distn gas for complete combustion.

Furnaces. L. and C. STEINMÜLLER. Ger. 511,566, Feb. 21, 1928. The furnace has an inclined hearth and an arrangement for charging the fore-hearth.

Industrial furnaces. ALFRED MUSSO. Fr. 690,925, Feb. 19, 1930. An industrial furnace, simple or in floors or multiple compartments, is described for carrying out chem reactions; it comprises a retort, means for creating a reduced pressure in the retort for the introduction of gases and, preferably, stirring means.

Heating industrial furnaces. THEODOR WUPPERMANN. Ger. 514,017, May 9, 1928. A grate on which fuel is partly burnt and partly gasified is provided, together with a sep. coal-dust burner. The secondary air for burning the fuel gasification products is supplied through the coal-dust burner.

Furnace for pulverized coal. ALLGEMEINE ELEKTRIZITÄTS-GES. (Friedrich Reinhardt and Theodor Schröder, inventors). Ger. 512,948, Dec. 17, 1926. The furnace has multiple air-blast nozzles in the fire-chamber cover.

Burners for powdered fuel. PERCY W. GRIFFIN. Fr. 692,340, Mar. 20, 1930

Coal-dust furnace plant. GEWERKSCHAFT DES BRAUNKOHLEN-BERGWERKS "JEAN PAUL." Ger. 512,868, Dec. 22, 1927.

Burner device for coal-dust furnace plant. STUG KOHLENSTAUBFEUERUNG PATENTVERWERTUNG. G. M. B. H. Ger. 511,829, Mar. 23, 1929.

Muffle furnaces. METALL-INDUSTRIE J. KLEPISCH Ger. 512,992, April 27, 1929 and 512,993, April 27, 1929.

Shaft furnace for inferior granular fuel. HEINRICH KÜPPERS Ger. 511,580, Oct. 14, 1928. Details of construction are given.

Shaft furnace for treating solid materials with gases. AKTIESELSKAPET NORSK STAAL (Elektrisk-Gas-Reduktion). Norw. 46,010, June 24, 1929. The reaction chamber of the furnace is built up by means of a number of separately removable containers, open at top and bottom, in which the solid materials are placed.

Grate furnace, with drying shaft for the fuel. FRANZ HOF SCHORNSTEIN- UND FEUERUNGSBAU and FRANZ HOF. Ger. 511,330, Jan. 3, 1930.

Inclined-grate furnace, with superposed grates. FIRMA K. H. PAUL LUDWIG Ger. 514,105, Sept. 29, 1929.

Travelling-grate furnace. L. and C. STEINMÜLLER. Ger. 511,532, Oct. 24, 1929

Travelling-grate furnace. A.-G. FÜR ZELLSTOFF- UND PAPIERFABRIKATION. Ger 511,662, Dec. 6, 1928.

Rotating furnaces. RENÉ P. É. ROMAN and THÉODORE LAFITTE. Fr 690,919, Feb. 17, 1930. An improved construction is described whereby pressures at all temps may be maintained.

Rotating furnace for cement, lime, ores, etc. MIKAEL VOGEL-JÖRGENSEN Fr 691,678 and 691,679, Mar. 10, 1930.

Rotary tubular apparatus for heating air or other gases supplied to rotary furnaces

or driers. GUSTAV BOJNER, ALFRED P. PEHRSON and ADAM H. PEHRSON. Ger. 513,123, Jan. 19, 1927. See Brit. 264,825 (*C. A.* **22**, 188).

Burners for twin wind furnaces. C. OTTO & Co. G. M. B. H. Ger. 511,515, Dec. 4, 1925. Addn. to 480,746. Details of arrangement are given.

Charging chamber furnaces. C. OTTO & Co. G. M. B. H. Ger. 511,017, July 10, 1928. Addn. to 480,763 (*C. A.* **23**, 5034).

Device for charging furnaces with different kinds of fuel simultaneously. GERSCHWEILER ELEKTRISCHE CENTRALE G. M. B. H. Ger. 511,964, Aug. 24, 1926.

Transportable device for charging shaft furnaces of rectangular cross-section. METALLGES A.-G. (Otto Hubmann and Franz Voerkel, inventors). Ger. 514,245, Feb 4, 1927.

Mechanical fuel-charging device. DEUTSCHE BABCOCK & WILCOX DAMPFKESSELWERKE A.-G. Ger. 512,741, July 26, 1928.

A suspended cover for a furnace. SCHEIDHAUER & GIESSING A.-G. (Hugo Ackermann, inventor). Ger. 512,702, June 9, 1928.

Automatic combustion regulator, particularly for boiler furnaces. SIEMENS-SCHUCKERTWERKE A.-G. (Ferdinand Köhler, inventor). Ger. 514,264, Mar. 16, 1927.

Regulating device for oil burners. ADOLF FROMHEIN. Ger. 498,042, Aug. 31, 1926.

Coal dust, oil, or gas burner for boilers. SCHMIDT'SCHE HEISSDAMPF-GES. M. B. H. Heinrich Peperkorn, inventor). Ger. 513,349, Mar. 27, 1927.

Gas burner. C. H. KEMPTON and W. BISSELL. Brit 335,256, June 21, 1929.

Gas burner (suitable for pilot lights of oil burners). AUGUSTUS J. FRAME (to Franklin Oil Heating, Inc.). U. S. 1,789,973, Jan. 27.

Slide valve for gas burners, particularly for blast heaters. ZIMMERMANN & JANSEN G. M. B. H. Ger. 513,109, Nov 29, 1928.

Electric water heater. L. P. HAUSSAUER. Brit. 335,323, Aug. 2, 1929.

Water heater and steam condenser. JOHN H. HUDSON. U. S. 1,790,306, Jan. 27.

Apparatus for heating molten salt baths, etc., by circulating oil. CHARLES C. PLUMB. U. S. 1,790,555, Jan. 27. Structural features.

Heat exchanger for gas mixtures. MESSER & Co. G. M. B. H. Ger. 512,825, Nov. 9, 1929.

Heat-exchange apparatus suitable for treating oil or other liquids. HARLAN W. HOW (to Struthers-Wells Co.). U. S. 1,790,151, Jan. 27. Structural features.

Heat-exchange apparatus suitable for use as a condenser. PATRICK J. MCINTYRE (to Wolverine Tube Co.). U. S. 1,789,591, Jan. 20. Structural features.

Heat-exchange apparatus (tank with internal coils and headers) suitable for cooling water or other liquids. NORMAN H. GAY. U. S. 1,789,739, Jan. 20. Structural features.

Tubular heat-exchange apparatus suitable for heating or cooling milk or other liquids. CLIFFORD MORROW (to H. H. Miller Industries Co.). U. S. 1,790,015, Jan. 27. Structural features.

Tunnel kiln. WOODALL-DUCKHAM (1920), LTD., DOULTON & Co., LTD., and C. BATEY. Brit. 334,951, June 14, 1929.

Preventing incrustation in rotary kilns. F. KRUPP GRUSONWERK A.-G. Brit. 334,868, April 20, 1929. To prevent incrustation in the preheating zone of a rotary kiln, the waste gases are throttled at the feed end of the kiln by dampers arranged to control the full cross section of the kiln and part of the gases is withdrawn through openings at the beginning of the reaction zone so that they do not contribute thereafter to the heating of the pre-heating zone. Various details of construction and operation are described.

Steam-heated apparatus. CURT ROSENBLAD. Ger. 513,287, Jan. 9, 1929. Means is described for increasing the thermal efficiency of steam-heated app. in which 2 or more coils or other heating surfaces are arranged in series. The app. includes a throttle and a water-separator between each two coils, etc.

Siphon apparatus for discharging liquids from tanks. AUGUSTINE DAVIS, JR. U. S. 1,789,864, Jan. 20. A system is described adapted for discharging liquid from any one of a plurality of assocd. tanks.

Lining molds. FRIEDRICH MAYER. Ger. 511,101, Oct. 30, 1923. A coating compn. for the inner surfaces of permanent molds consists exclusively of an aq. colloidal soln. of a mineral substance, *e. g.*, graphite, talc or clay.

Machine for making threaded castings from celluloid or like plastic material. NIEDERRHEINISCHE MASCHINENFABRIK BECKER & VAN HÜLLEN A.-G. Ger. 514,039, Aug. 29, 1929.

Apparatus for drying salt crystals. ADLER & HENTZEN MASCHINENFABRIK. Fr 690,651, Feb. 25, 1930.

Combined drying drum and ball mill. BERNHARD SÄGEBARTH. Ger. 513,280, Mar. 19, 1927.

Device for the continuous drying of casein, etc. PASQUIER, MEESE & CIE. Ger. 511,543, Mar. 10, 1928. Details of arrangement are given.

Acetylene generator. ÉMILE LAUFFER. Fr. 691,712, Mar. 11, 1930.

Acetylene generator. JACOB KNAPPICH. Ger. 511,403, Nov. 10, 1929. The lime and water removed from the generator are passed through a closed container having a gas space connected to that of the generator. Gas from unreacted particles of carbide is thus recovered.

Acetylene generator (water to carbide type). JOHANNES BUTTGEREITH. Ger. 513,049, Nov. 24, 1928.

Acetylene generator (carbide to water type). CARL KEEL. Ger. 514,107, May 11, 1929.

Closure for acetylene generator. AUTOGENWERK SIRIUS G. M. B. H. Ger. 511,136, May 25, 1929. Addn. to 489,089 (*C. A.* **24**, 2017).

Apparatus for stretching thin disks of material such as viscose or "cellophane" after softening for making sound records. A. A. PENTEADO. Brit. 334,830, June 12, 1929. Structural features.

Thermostat for control of electric circuits. ADOLPH A. THOMAS. U. S. 1,780,608, Jan. 20. Structural features.

Thermostatic device suitable for control of electric heaters, etc. REUBEN S. TICE and ARTHUR L. HOLCOMB. U. S. 1,790,121, Jan. 27. Structural features.

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

Professor Dr. Adolf Cluss. W. KLUGER. *Oesterr. Chem.-Ztg.* **34**, 11–2(1931). Obituary. F. H.

Edward Morell Holmes. TSCHIRCH. *Schweiz. Apoth. Ztg.* **68**, 551–3(1930). A necrology and personal reminiscences. S. WALDBOTT

František Wald (1861–1930). J. BABOROVSKÝ. *Chem. Obzor.* **5**, 281–3(1930); cf. *C. A.* **25**, 626.—Biographical sketch with a portrait. J. KUČERA

František Wald. J. Z. SCHNEIDER. *Chem. Obzor* **5**, 283–6(1930).—Obituary. J. KUČERA

Amount of ozone in the earth's atmosphere and its relation to other geophysical conditions. IV. G. M. B. DOBSON, H. H. KIMBALL AND E. KIDSON. *Proc. Roy. Soc.* (London) **A129**, 411–33(1930); cf. *C. A.* **23**, 2612.—The distribution of O_3 in regions occupied by cyclones or anticyclones was shown graphically, also the av. distribution over the world. Possible methods of formation and decompn. of O_3 are discussed. FRANK URBAN

A new relation chart of the carbohydrates. C. W. EDDY. *J. Chem. Education* **7**, 2692–6(1930).—A chart is presented that is designed to aid the student in visualizing the configurational and chem. interrelationships in the monosaccharide group. The chart is similar to that of Rosanoff (*J. Am. Chem. Soc.* **28**, 114(1906)) but employs actual structural formulas instead of schematic symbols. The possible chem. inter-transformations are indicated by arrows of four different types representing, respectively, (1) the Kiliani synthesis, (2) the Van Ekenstein transformation, (3) exchange of aldehyde and primary alc. groups and (4) transformations between aldoses and ketoses. R. C. HOCKETT

Mathematical color definition from photoelectric measurements. HAROLD D. ELLSWORTH AND PAUL MCMICHAEL. *Am. Photoelec. Corp., New York City, Separate* 8 pp.; in briefer form in *Electronics* Oct. No., 1930; cf. *C. A.* **24**, 1531. E. J. C.

Determination of structure with acoustic oscillations. A. MEISSNER. *Z. Physik* **65**, 145–57(1930).—A plate of quartz is excited with high frequency and the elec. axes are found from the glow discharges which appear when the crystal is placed in a vacuum or from the mech. oscillations revealed with the help of lycopodium. By combining the observations made on various quartz plates, it is found that the three elec. axes are very nearly perpendicular to each other. On the assumption that their direction corresponds to the planes of greatest d. of the Si atoms, the correct at. distance is obtained from the d. and Avogadro's no. From the optical activity of quartz, the size

of the elementary cell and the no. of atoms in it are deduced from purely macroscopic measurements. EGON BRETSCHER

Micro-stereo observations and their photographic measurement. RUDOLF LORENZ. *Papier-Fabr.* **28,** Tech.-Wiss. Teil, 805–9(1930).—An app. for taking stereophotomicrographs is described, and a method of estg. the thickness of the object illustrated, for kaolin particles (av. 1μ thick). The possible value of such methods in *measuring paper* and *textile fibers* is pointed out. R. H. DOUGHTY

Metallic reflection. JOSEF ZAHRADNIČEK. *Z. Physik* **65,** 814–23(1930).—The formulas for metallic reflection are obtained in a more general form than by Drude. Measurements of the reflecting power are carried out on the (100) face of PbS, with light of λ = 5875.7 A. U. EGON BRETSCHER

Freezing point of nickel as a fixed point on the International Temperature Scale. H. T. WENSEL AND WM. F. ROESER. *Bur. Standards J. Research* **5,** 1309–18(1930).—The f. p. of Ni was detd. by measuring with an optical pyrometer the ratio of brightness of red light of a wave length 0.6533μ emitted by black bodies at the f. ps. of Ni and Au, resp. The Ni was frozen in magnesia crucibles *in vacuo*. The f. p. was found to be 1455° (on the International Temp. Scale) with an uncertainty of 1°. The temp. coeff. of resistance of the 2 sep. ingots of Ni used was approx. 0.0067 in the interval 0–100°. The chem. analysis indicated the Ni to be 99.94% pure. The importance of the Ni point in optical pyrometry is discussed. The f. p. of pure Ni in magnesia crucibles was found to be very satisfactory as a fixed point in accurately extending the high temp. scale beyond the Pt point. LEOPOLD PESSEL

A heterodyne method for determining the dielectric constant of conducting liquids. W. GAEFUNDER AND R. WEBER. *Z. Physik* **65,** 723–5(1930).—The usual heterodyne method of *measuring* the *dielec. const.* is restricted to insulators. To measure conducting liquids a variable resistance is set across the measuring capacity and this resistance is adjusted so that the damping is the same if the capacity contg. the conducting liquid is connected to the circuit or the measuring capacity + resistance. A valve voltmeter is used to control the damping and a variable resistance (whose capacity must remain const. for all values of resistance) is built up from two radio tubes, whose resistance is varied by adjusting the filament current. EGON BRETSCHER

Comparison of two methods for determining the contact potential between two metals. GUNTHER MÖNCH. *Z. Physik* **65,** 233–43(1930).—The contact potentials of Cu-Fe (—0.35 v.), Cu-Ni (—0.23 v.) and Cu-Ag (+0.03 v.) were measured by Thomson's method of variable capacity. A process of detg. the shift of the anode characteristics in a radio tube that contains the metal combination on the grid is described. Both methods give the same results with an accuracy of 0.01 v. EGON BRETSCHER

The automatic maintenance of solid-liquid equilibrium in metals. PAUL A. ANDERSON. *Rev. Sci. Instruments* **1,** 764–7(1930).—The method is based on the abrupt change in resistivity at isothermal fusion, and is generally applicable to pure metals. A diagram shows the connections by which a Zn bath was held at its m. p. for 12–48 hrs. in the prepn. of *single metal crystals*, the current being controlled by a photoelec. cell. The app. functioned satisfactorily for 18 mos. J. H. MOORE

Relative advantage of ring marks vs. point indicators for determining gas specific gravity by the Bunsen-Schilling apparatus. L. ZIPPERER AND W. ROTTENGATTER. *Gas u. Wasserfach* **73,** 1190–2(1930).—The point indicator permits a higher degree of precision in sp. gr. readings, and decreases the discrepancy between several observers, as compared with the usual ring marks. R. W. RYAN

Relation of molecular polarization of propyl chloride and 1,2-dichloroethane to temperature, especially regarding free rotation. R. SÄNGER. *Physik. Z.* **32,** 21–6(1931). Consideration is given detns. of mol. polarization, P, of propyl chloride. There exists a linear relationship between P and $1/T$. The elec. moment is calcd. as $2.040 \pm 0.007 \times 10^{-18}$. Comparison is made with MeCl and EtCl. A theoretical discussion and interpretation of the data are given. The results lead to the conclusions that either there is unhindered free rotation of the end groups C—Cl and C—CH_3 about the axis of the C—C bond or that two mol. forms exist in approx. const. ratio. Original data on 1,2-dichloroethane are tabulated. P does not vary linearly with $1/T$; this agrees with other data. The fact is interpreted on the basis of pure assocn. at lower temps. The permanent elec. moment may be explained on the basis of a strong deformation of the carbon valence tetrahedra in the C—C bond, while the possibility of unhindered free rotation is retained. WILLIAM E. VAUGHAN

Dependence of molecular polarization on temperature and its relationship to free rotation. LOTHAR MEYER. *Z. Elektrochem.* **36,** 743–6(1930); cf. *C. A.* **24,** 4194. A. P. SACHS

Quantized rotation of atoms. E. LOEDEL-PALUMBO. *Physik. Z.* **31**, 926-9 (1930).—Loyarte's "addn. potential" of 1.4 v. for Hg and his const. $\Delta\nu = 11{,}316$ have no phys. meaning. As good agreement may be obtained with many other arbitrary values, in harmony with probability calcns. The idea of a quantized rotation of the Hg, K and Tl atoms lacks a phys. foundation. FRANK URBAN

The existence of the addition and subtraction potential of 1.4 v. in the mercury atom. R. G. LOYARTE. *Physik. Z.* **31**, 929–39(1930).—A crit. discussion based on the data of Franck and Einsporn (*C. A.* **14**, 3360); Jarvis (*C. A.* **21**, 3153); Pavlov and Sueva (*C. A.* **23**, 3626). FRANK URBAN

The drying of gas streams. LOUIS L. BIRCUMSHAW. *J. Chem. Soc.* **1930**, 2213–5 A stream of H_2 (flowing at 15 cc./min. for 6 hrs.) must be so dried that during its prolonged passage through Pb, Sn, etc., heated just above their m. ps. no oxide film is formed. It is shown that the ice fog formed on sudden cooling in the first trap (constructed as usual) is destroyed by passing through a length of glass tubing at room temps., and the resulting water is collected in the next trap. In the method chosen from several as the most effective and the cheapest, the gas is passed through the first trap, immersed in a thermos flask contg. an ice-salt mixt., then by means of a short length of lagged tubing connected to it through a second trap in solid CO_2-acetone, and finally through a long piece of glass tubing and a third trap. With this method a heavy ring of ice is observed in the second trap, and at most only the faintest trace in the third trap. J. BALOZIAN

The critical constants of carbon dioxide-oxygen mixtures. H. S. BOOTH AND J. M. CARTER. *J. Phys. Chem.* **34**, 2801–25(1930).—Crit. phenomena were observed in 5 different mixts. of CO_2 and O_2 contg. 50, 60, 70, 80 and 90% O_2, resp. This investigation covers the range of higher O content than original work of Keesom (*Z. physik. Chem.* **54**, 498(1906)). Tables and graphs show the temp.-pressure relations for the above mixts. for pressures up to 140 atms. and temps. to —65°. Crit. temp. and max. temp. of condensation decrease with increase in O_2 content of the mixt. Retrograde phenomena were observed for all mixts. A thermodynamic explanation is given. The soly. of solid CO_2 in liquid O_2 near its crit. point was demonstrated by the fact that a liquid mixt. of CO_2 and O_2 can be obtained at a temp. of —115° which is 3° above the crit. temp. for O_2. H. M. STARK

Light scattering at the critical point. G. PLACZEK. *Physik. Z.* **31**, 1052–6(1930); cf. Ornstein and Zernike, *C. A.* **21**, 3152.—The dimensions of the scattering vol. must be considered in light scattering at the crit. point. If this is taken account of, the objections of Rocard to the Ornstein-Zernike theory are not substantiated. Formulas for lateral scattering and extinction are given on which exptl. tests of this theory can be made. S. LENHER

Remarks on the van der Waals' equation. E. NEUSSER. *Physik. Z.* **31**, 1041–51 (1930).—The coeffs. a and b of van der Waals' equation, assumed to be independent of pressure and temp., are calcd. from vols. measured at 2 but slightly diff. pressures and at the same temp. The exact value of the gas const. R is calcd. as 0.082051 atms./degree mol. and the ice-point is calcd. as 273.20° T. Dependence of the exptl. values of a and b for H_2 and CO_2 on pressure and temp. are given in diagrams. The vapor pressure of CO_2 from 0° to 30° and approx. crit. data are calcd. S. LENHER

Direct relationship of equation of state and internal friction. LEON SCHAMES *Physik. Z.* **32**, 16–20(1931).—A theoretical discussion. The virial coeffs. of He, H_2, Ne, N_2, air, A and O_2 at various temps. are tabulated. WILLLIAM E. VAUGHAN

Determination of viscosity at low temperatures. ERNST SCHLENKER. *Brennstoff Chem.* **12**, 25–6(1931).—The difficulties encountered are discussed briefly. A simple app. is described whereby the time required at the temp. desired for oil or other liquid to climb to a height in a capillary-tipped pipet compensating a certain water displacement in a closed vessel connected to the top of the pipet, is used to compare viscosities. Viscosity curves obtained for different heights of rise through adjustment of the discharge tube on the bottom of the displacement vessel, are not wholly parallel, possibly because of small pressure differences due to altitude variations. Ingress of air moisture to the oil cup, which is surrounded by a double salt-ice bath and cover fitted with thermometer, is prevented by a $CaCl_2$ tube while a film of oil on the water in the displacement vessel seals the other end of the pipet from moisture. By the use of a receiver under the discharge water tube, immediate return of the oil to the cup and rapid repetition are possible by the raising of the displacement vessel. Max. differences in time of only 2% were obtained at temps. of —20° to +50°. For standardization, an oil is used which at 20° has a viscosity of 20° Engler and is equivalent to a climbing time of 50 sec. F. W. JUNG

Comparative methods for determining viscosities of liquids. A. TER-POGOSYAN. *Azerbaidzhanskoe Neftyanoe Khozyaistovo* **1930**, No. 11, 120–7.—Notwithstanding certain defects of the Engler viscometer it is satisfactory for practical work provided the formula of H. Vogel (*C. A.* **17**, 318) is used for interpreting results in abs. units. For kinematic viscosities below 2, Engler viscometer readings are not comparable with abs. viscosities, but Stoke's formula and the torsion-balance method give satisfactory results. V. KALICHEVSKY

Equations for vapor pressure and latent heats including approximate equations for solid compounds containing a gaseous component. LOUIS J. GILLESPIE. *Proc. Am. Acad. Arts Sci.* **66**, 153–65(1930).—A math. paper in which, by a method similar to Gibbs', thermodynamic equations are derived for vapor pressures and latent heats as well as approx. equations for decompn. pressures of solids and their latent heats. Methods for applying the equations to exptl. data are given. E. R. SCHIERZ

Vapor pressure of a liquid. I. Vapor pressure, heat of vaporization and chemical constant of a pure liquid substance. KEIICHI WATANABE. *Sci. Repts. Tokyo Bunrika Daigaku.* Sect. A, **1**, 1–13(1930).—For the vapor pressure of a pure liquid in air at P atm. pressure is given the equation: $\ln p = \alpha(P - p) - \frac{(U_2 + PV_2) - (U_1 + PV_1)}{RT} + \left(\int^{T} \frac{C_{1p}}{RT} dT\right)_{(P)} - \left(\int^{T} \frac{C_{1p}}{RT} dT\right)_{(P)}$ where the equation of state of the vapor is $pV_2 = RT(1 + \alpha P)$. p is the vapor pressure of the liquid, U and V are the internal energy and vol., resp. of one mol. of substance, C_p is the mol. heat at const. pressure, R the gas const. and T the abs. temp. Subscript 1 denotes the liquid state and subscript 2, the vapor state. The chem. const. and heat of vaporization also are discussed. P. T. NEWSOME

The vapor pressures of selenium tetrachloride. The existence of selenium dichloride. DON M. YOST AND CHARLES E. KIRCHER. *J. Am Chem. Soc.* **52**, 4680–5(1930).—By vapor-pressure and vapor-density measurements it is shown that, over the temp. range 100° to 220°, the vapor from $SeCl_4$ consists entirely of $SeCl_2$ and Cl_2. P. T. NEWSOME

Boiling- and dew-point curves for mixtures of ethyl alcohol and water up to fifteen atmospheres. JOH. A. GRUMBT. *Tech. Mech. Thermodynamik* **1**, 309–15, 349–57 (1930).—EtOH-H_2O mixts. studied in a bomb and examd. with the refractometer, aneroid barometer and resistance thermometer give the relations between boiling points and dew points at higher pressures and temps. Detd. curves are given at 1.033, 3, 5, 12 and 15 atms. and calcd. to 1–15 atm. in 0.5 atm. intervals. F. D. S.

Diffraction of x-rays in liquids: effect of temperature. E. W. SKINNER. *Proc. Iowa Acad. Sci.* **36**, 306–7(1929).—With an x-ray spectrometer similar to that used by G. W. Stewart, expts. were carried out on the effect of varying temp. on scattering by cyclohexane (27° and 83.5°) and heptylic acid (28° and 193°). The planar spacing giving the distance between mols. increases with increase in temp. (0.28 A. U. for heptylic acid and 0.16 A. U. for cyclohexane). This change is attributed to the vol. expansion of the liquid. In heptylic acid, the dimension denoting the length of the mol. was not changed, which shows that expansion takes place in only one direction relative to the lengths of the mols. The width of the peak increases at the higher temps. This is due to the disrupting of the mol. groupings by thermal agitation, which produces a more diffuse scattering. With increase in temp. a decrease in intensity (about 20%) of the peak denoting mol. widths was observed. This is probably due to (*a*) expansion of the liquid, (*b*) disarrangement of the scattering centers. These results and conclusions are found to be in harmony with the theory of the cybotactic condition. W. G. G.

Further investigation of x-ray diffraction in liquids. II. Benzene, cyclohexane and their homologs. SHINSUKE TANAKA AND AKIRA TSUJI. *Mem. Coll. Sci. Kyoto Imp. Univ.* Ser. A **13**, 169–73(1930); cf. *C. A.* **24**, 3163.—With narrow slits instead of circular openings to limit the x-rays, x-ray diffraction pictures were obtained for benzene, toluene, ethylbenzene, *o*-, *m*- and *p*-xylene, mesitylene, pseudocumene, isopropylbenzene, *p*-cymene, cyclohexane, cyclohexene, methylcyclohexane and 1,3-dimethylcyclohexane. A second max. found in the diffraction band for C_6H_6 enabled the diam., 4.76 A. U., and the thickness, 3.13 A. U., of the C_6H_6 mol. to be calcd. Cyclohexane and its homologs gave a single sharp max., which indicates a spherical mol. form. III. **Influence of temperature.** *Ibid* 337–42.—X-ray diffraction bands were photographed for pyridine, pyrrole, cyclohexane, nitrobenzene, heptane, heptyl alc. and oleic acid at temps. ranging from —9° to 225°. The position of the diffraction bands decreased, the bands became wider and the edges more diffuse, the inner scattering increased and the intensity decreased with rise of temp. MALCOLM DOLE

X-ray diffraction by organic solutions. ALFRED W. MEYER. *Proc. Iowa Acad. Sci.* **36**, 303–4(1929).—Series of ionization diffraction curves of 2 org. solns. with varying concns. were obtained with Mo K_α radiation. The solns. used were BuOH with *o*-dimethylcyclohexane and EtOH with cyclohexane. The diffraction peaks shift from the peak of one member to that of the other as the soln. changes from 100% of one member to 100% of the other. Also the width of the peak varies in the same manner except that the width is a max. at a low percentage of the liquid, the peak of which is of least width. There is no evidence of a double peak, indicating that the liquids do not diffract individually. A curve is obtained by using the components separately but measuring the diffraction of both liquids simultaneously and this curve clearly shows the peaks of both liquids. This proves that the spectrometer can resolve the peaks of both liquids if they are present in the diffraction by the solns. Stewart, Morrow and Skinner (*C. A.* **22**, 1098) have shown that the diffraction peaks of org. liquids indicate a grouping of the mols. and that the Bragg law approx. the spacings. The soln. diffraction curves then indicate that the mols. of both constituents form a single type of group and that the spacing is detd. by the proportion of the constituent present. The width of the curve may indicate that the grouping is less perfect than in the pure liquids. These conclusions are very similar to those found in the case of the diffraction by solid soln. W. G. GAESSLER

The nature of the solid state. M. POLANYI. *Umschau* **34**, 1001–7(1930). This is an address on the solid state, cryst. (ordered) and amorphous (unordered), accompanied by drawings of models and photographs of cryst. metals illustrating the effect of pressure and tension on the orientation of the atoms in the crystal lattice. E. R. S.

Atomic sizes and isomorphism. G. NATTA AND L. PASSERINI. *Atti III congresso naz. chim. pura applicata* 1930, 365–70.—By the powder method, x-ray examn. of 2- and 3-component systems of certain bivalent oxides and hydroxides shows a classification into 3 groups (cf. *C. A.* **23**, 4124). These are complete soly., partial soly. or immiscibility. With the radius of the O ion as 1.32 A. U., radii of the bivalent cations in A. U. are: Zn, 0.75; Ni, 0.77; Mg, 0.78; Co, 0.80; Fe, 0.82; Mn, 0.89; Cd, 1.01; Ca, 1.08. Two cubic oxides of bivalent metals will form solid solns. in all ratios, if the at. radius of the larger cation is not greater than 13% of the other. For partial soly., the difference between the radii must be less than 25%. No solid soln. is obtained when the difference is greater than 30%. For 3 oxides, the limit of soly. increases with increase in the size of the elementary cell. For 3 rhombic hydroxides, the ratio of the at. radii must be 16% for soln. For carbonates, the ratio is 30%. G. M. MURPHY

Systematic structure theory. II–IV. C. HERMANN. *Z. Krist.* **69**, 226–70, 250–70, 533–55(1929). B. C. A.

Crystal structure of anhydrous halides of the bivalent metals. ADOLFO FERRARI. *Atti III congresso naz. chim. pura applicata* 1930, 452–60.—Cell consts. and other data are given for fluorides of Mg, Zn, Ni, Co, Fe and Mn, that belong to the *rutile* type, and for those of the *fluorite* type, Cd, Ca, Sr, Pb and Ba. It is not yet possible to establish the existence of 2 isomorphous series for the chlorides and bromides. The chlorides of Pb, Hg, Ni, Co, Mg, Fe, Mn, Cd, Zn, Ca, Sr, Pb and Ba and the bromides of Zn, Sn, Hg, Pb, Co, Fe, Mg, Mn and Cd are discussed. The iodides of Co, Fe, Mn, Cd and Pb belong to the CdI_2 type. G. M. MURPHY

Relation between point of fusion and crystal structure. ADOLFO FERRARI. *Atti III congresso naz. chim. pura applicata* 1930, 449–51.—For the halides of Li, Na, K and Rb, the m. p. decreases with increasing at. wt. in passing from fluoride to iodide. For halides of Co, Fe, Mg, Mn, Pb and Hg, the regularity holds only for Co. For a face-centered crystal lattice, the m. p. is approx. represented by $(\sqrt{\text{at. wt.}} \times 270) - 5$. The following numbers give a in A. U., exptl. m. p. and calcd. m. p. for V, Mo, W, Ta resp.: 3.04, 1988, 2085; 3.14, 2773, 2690; 3.155, 3643, 3670; 3.272, 3303, 3386. For a body-centered crystal lattice, the formula is $\sqrt[4]{\text{at. wt.}} \times 400$. The results, as before, for Al, Ag and Au, are: 2.86, 931, 912; 2.876, 1233, 1288, 2.87, 1336, 1199. G. M. MURPHY

Water in the crystal lattice. GIULIO NATTA. *Atti III congresso naz. chim. pura applicata* 1930, 347–64.—Examn. of the crystal structure of $SrO_2.8H_2O$ by the powder method shows that it belongs to the tetragonal system with 1 mol. in the elementary cell. Its vol. is 222×10^{-24} cc., a = 6.32 A. U., c = 5.56 A. U. The vol. is smaller than that of $Sr(OH)_2.8H_2O$ (cf. *C. A.* **23**, 3178). A similar structure is obtained with $ZrOCl_2.8H_2O$ and with $BeSO_4.4H_2O$. For the latter, a = 5.62 A. U., c/a = 0.946, d. calcd. = 1.754, d. exptl. = 1.725. The diams. of the bivalent O in the H_2O of crystn. and the Sr ion are, resp., 2.06 and 2.54 A. U. The av. value of the vol. of the OH ion

in 6 bivalent rhombic hydroxides is 16.75 × 10^{-24} cc., from which the g.-mol. vol. of H_2O is 14.2 cc. Hydrates of variable compn. such as those of Co and Sb are discussed. Classification of hydrates in the following 4 groups is suggested. (I) Hydroxides, with definite compn. They contain strongly polarizable OH ions, with a vol. of approx. 16 × 10^{-24} cc. (II) Hydrates of definite compn. The H_2O is distributed in a definite way around the coördinate ion and has a vol. of about 23.5 × 10^{-24} cc. (III) Hydrates of indefinite compn. in which the H_2O enters the crystal lattice but does not alter the position that the atoms would occupy in the anhydride. (IV) Hydrates of indefinite compn., the H_2O not penetrating the crystal lattice but being retained by capillarity or superficial absorption. G. M. MURPHY

Crystal structure of silicon. A. G. NASINI AND A. CAVALLINI. *Atti III congresso naz. chim. pura applicata* 1930, 463–70.—Samples of Si were obtained from Al and Zn alloys, from K_2SiF_6, from thermal decompn. of $SiHCl_3$, hydrolysis of SiS_2, and decompn. of SiH_4. All show the characteristic diamond-type structure with a = 5.421 A. U. for the $K\alpha$ ray of Cu. The powder method was used. The Si prepd. from SiS_2 and SiH_4 gave diffuse spectrograms, characterized by minute cryst. particles. G. M. MURPHY

Crystal structures of organic compounds. STERLING B. HENDRICKS. *Chem. Reviews* 7, 431–77(1930).—A review is given of x-ray results that have a bearing on structural org. chemistry. The difficulties of x-ray analysis arise from the low symmetries of org. compds. and undetd. intensity factors of radiation scattered from atoms of low at. no. such as O, N, C and H. X-ray data lead to a detn. of the unit of structure and space group of the compd., symmetry of the mol., and position of each atom in the mol. In iodoform, the hexagonal unit of structure contg. 2 mols., has a = 6.87 A. U., c = 7.01 A. U. with I atoms at space-group C_6^6. The min. mol. symmetry is probably a 3-fold axis. The min. I-I distance in the same mol. is 3.57 A. U., while the I atoms of 2 mols. are at the corners of octahedra with edges 3.94 and 4.43 A. U. In hexabromo- and hexachloro-cyclohexane the cubic units of structure contg. 4 mols. have a = 10.49 A. U. ($C_6H_6Br_6$) and a = 10.07 A. U. ($C_6H_6Cl_6$). The halogen atoms are at space-group T_h^4. The min. mol. symmetry is a 3-fold axis and a center. The assumed structure gives a tetrahedral distribution of the C valences. For C_2Cl_6, C_2Br_6, $C_2Cl_4Br_2$, $C_2Br_4F_2$, $C_2Cl_2Br_2$ and $(CH_3CBr_2)_2$ the dimensions of the orthorhombic unit of structure contg. $4C_2X_aY_{6-a}$ are summarized by table. The space-group is V_h^{16}. Both cryst. modifications of $C_2Cl_4Br_2$ have the probable formula CCl_3CClBr_2. Iodosuccinimide, *m*-iodobenzoic acid, CI_4, CBr_4, hexachloro- and hexabromo-benzene, tetrachloronaphthalene, and 1,2,3,4,5,8-hexachloronaphthalene 1,2,3,4-tetrahydride also were examd. Interference in x-radiation and electron beams scattered from vapors of org. compds contg. Cl are noted. CCl_4 patterns show that the Cl-Cl distance in a mol. is 3.3 A. U. or 3.14 A. U. while the corresponding C-Cl distance is 2.02 or 1.91 A. U. The Cl-Cl distances in *cis*- and *trans*-1,2-dichloroethylene and 1,1- and 1,2-dichloroethane are a_{cis_2} = 3.6 A. U., a_{trans} = 4.1 A. U., $a_{1,1}$ = 3.4 A. U., and $a_{1,2}$ = 4.4 A. U. The structure of diamond is cubic with each C atom surrounded by 4 others at the corners of a regular tetrahedron. The C-C distance is 1.54 A. U. The structure of graphite is hexagonal with the C atoms in one plane 1.42 A. U. apart at closest approach forming a hexagon. The C-C distance in separate planes is at least 3.40 A. U. For hexamethylenetetramine the body-centered cubic unit of structure contg. $2C_6H_{12}N_4$ has a_0 = 7.02 A. U. Each C atom is surrounded by 4 atoms, two of which are N at the vertices of a regular tetrahedron. The N atoms are equidistant from 3 C atoms, but are not in the C atom plane. The min. N-C distance is about 1.44 A. U. Only the possible H positions are indicated. Urea is tetragonal with 2 mols. in the unit with a = b = 5.73 A. U., and c = 4.77 A. U. The urea mol. has C-O distance 1.05–1.42, C-NH_2 1.07–1.30 A. U. Crystal structures bear out the heteropolar characteristics. The at. positions for orthorhombic $CS(NH_2)_2$ have not been detd. The complete structure of CH_3CONH_2 is undetd.; the mol. is asym. (space-group C_{2v}^6). Hexamethylbenzene is the only aromatic compd. whose structure is satisfactorily detd. It is triclinic with one mol. in the unit. The space-group is C_i^1 a = 9.010, b = 8.926 and c = 6.344 A. U. with $[\alpha]$ = 44° 27′, $[\beta]$ = 116° 43′ and $[\gamma]$ = 119° 24′. Methane at liquid H temps. has a cubic close-packed structure with a_0 = 6.35 A. U. Ethane has a hexagonal unit contg. $2C_2H_6$ with a = b = 4.46 A. U. and c = 8.19 A. U. The methane and ethane mols. are rotating groups. For long-chain aliphatic compds. some data are summarized graphically. The increases in spacing with the addn. of a methylene group are (1) about 1.30 A. U.; (2) about 2.60 A. U.; (3) intermediate values (1) and (2) are the changes or twice the changes in length of the chain while

(3) are due to a co-planer "zig-zag" arrangement of C atoms. Nonacosane is probably orthorhombic with 4 mols. in unit. The space group is C_{2v}^9. Detailed results were obtained for $C_{36}H_{72}$ and $C_{70}H_{142}$(?) Crystals of lauric, stearic, bromostearic, stearolic and behenolic acids are monoclinic prismatic; the space-group is C_2^h. The x-ray results together with measurements for some dicarboxylic acids are tabulated. X-ray patterns from single crystals of primary, tertiary and quaternary alkylammonium halides, tetramethylammonium perchlorate and permanganate, and alkylammonium chlorostannates and chloroplatinates were measured. Primary *n*-amylammonium chloride, taken as typical, is tetragonal; at room temp. it has 2 mols. in unit with $a = b = 5.01$ A. U. and $c = 16.69$ A. U. At liquid-air temps. the true structure contains 4 mols. in the unit cell with $a = b = 7.0$ A. U. and $c = 16.6$ A. U. "Rotation of the mol. about its long axis takes place at room temp. in the solid state giving rise to a pseudo unit. The space-group is C_{2h}^5 and the structure monoclinic for naphthalene, anthracene, biphenyl, phenanthrene, fluorene, bimesityl and bibenzyl The width of the benzene ring is proposed as 2.50 A. U. For *o*-, *m*- and *p*-dinitrobenzenes unit of structure and space-group detns. are given by table. Fiber diagrams of cellulose, hair, muscle, etc. are in accord with the phys. properties of the materials. The at arrangement in each class of compds .is shown diagrammatically, with the mol. configurations, units of structure and mol. symmetries. Seventy-seven references are included.

H. W. WALKER

Molecular structure of benzene, cyclohexane and their derivatives—a study in x-ray diffraction. G. W. STEWART. *Proc. Iowa Acad. Sci.* **36**, 305–6(1929); cf. *C. A* **24**, 1261.—An examn. by the x-ray diffraction ionization method was made of C_6H_6, toluene, *o*-, *m*- and *p*-xylene, mesitylene, EtPh, isopropylbenzene, cyclohexane, methylcyclohexane, *o*-, *m*- and *p*-dimethylcyclohexane, phenol, aniline, cyclohexanol, cyclohexanone, 2-hydroxy-1,3-dimethylbenzene *o*-, *m*- and *p*-toluidine, and *o*-, *m*- and *p*-cresyl methyl ether. The diffraction peaks are taken to be caused by the semi orderly space arrangement of the mols. in the liquid, or cybotactic condition and the distances of sepn. of the planes contg. diffraction centers are computed by Braggs' diffraction law. Both assumptions have previously proved justifiable (cf. *C. A* **22**, 1098; **24**, 3409). The structures of the C_6H_6 and cyclohexane rings are shown to be distinctly flat, having a thickness of 4.70 A. U. and 5.10 A. U., resp. The proof of the flatness rests upon the effect of substitutions and the relative prominence of diffraction peaks. The general dimension in a plane perpendicular to the thickness is indicated by a diam. of approx. 6 A. U. The similarity of the thickness to the diam of paraffin and alc. chain indicates the general correctness of the ring conception It is shown that the thicknesses of the C_6H_6 and cyclohexane "rings" depend upon the relative positions of the substituents. The conclusions are in harmony with current investigations from other viewpoints and strengthen the theory of semi-orderly and temporary space arrangements of the mols. in a liquid, or the cybotactic condition

W. G. GAESSLER

Crystal forms of single crystals of copper. I. Crystals produced by the stress-annealing method. SETSUZO TAKEYAMA. *Mem. Coll. Sci. Kyoto Imp. Univ.*, Ser A, **13**, 353–62(1930).—The outer crystallographic form of the Cu crystals obtained by the stress-annealing method *in vacuo* and those developed by etching were examd. by the method of optical reflection and by photomicrographs. It was found that the crystal faces developed depended on the manner of treatment of the surface of the crystal. Fine structures of the etching figures were also observed. Polysynthetic twinning relation of the spinel type was detected in the part of the crystal that showed banded structures. **II. Crystals deposited on the surface of a single crystal plate by electrolysis.** *Ibid* 363–7.—By electrolyzing Cu on to a single crystal of Cu, it was possible to obtain a perfect single crystal of the same orientation as that of the mother crystal at first, but continued deposition gave rise to microcrystals having orientations scattered somewhat from that of the mother crystal. MALCOLM DOLE

Peltier effect in single crystals of bismuth. H. D. FAGAN. *Proc. Iowa Acad. Sci.* **36**, 300–1(1929); cf. *C. A* **24**, 3163.—Some preliminary data on the Peltier effect in Bi single crystals are obtained. The reference metal used is Cu. The results so far obtained seem to be in fair agreement with the data computed from the thermal e. m. f measurements of Boydston (*C. A.* **22**, 720) and Bridgman (*C. A.* **19**, 425; **20**, 326; **23**, 1328, 2620). W. G. GAESSLER

Thomson effect in single-crystal zinc. L. A. WARE. *Proc. Iowa Acad. Sci* **36**, 301(1929).—Results for a series of crystals made from Kahlbaum Zn are much more consistent than any previously reported by W. (*C. A.* **22**, 4295; **24**, 1263; 3687). The

Voigt-Thomson symmetry relation appears to be satisfied for the Thomson effect. The sp. resistance and temp. coeff. of resistance were also measured for all the crystals.
W. G. GAESSLER

Resistance change in a magnetic field of single crystals of bismuth. ROY A. NELSON AND G. R. WATSON. *Proc. Iowa Acad. Sci.* **36**, 304(1929).—The work is a continuation of that of Schneider (*C. A.* **22**, 3822). Crystals were made from several different samples of Bi and by 2 methods. The fractional change in a longitudinal field of about 3000 gausses is found to be a min. for 0° orientation and a max. for 90°. The crystals, however, fall into 2 classes, the reason for which has not been detd. The supposition of any considerable fissures along the cleavage planes appears unlikely.
W. G. GAESSLER

Calculation of the limit of plasticity of polycrystalline aggregates from v. Mises' equations for the plasticity of single crystals. JOH. DEJMEK. *Z. Physik* **65**, 139–43 (1930).—Math.
EGON BRETSCHER

Piezoelectric experiments on the principle of the method of Giebe and Scheibe. ALFRED HETTICH. *Z. Physik* **65**, 506–11(1930).—An improved oscillator especially suitable for piezoelec. expts. is described and the method is used to study the piezoelec. properties at various temp. *Pentaerythritol* remains piezoelec. up to the point of decompn. KIO_3 is piezoelec. and therefore cannot belong to the monoclinic prismatic class. A point of transition exists possibly between 140° and 150°. CCl_4 is not piezoelec. at −80°. *Camphor* seems to change its modification at low temp. E. B.

The change of resistance of purest electrolytic iron in a longitudinal magnetic field. O. STIERSTADT. *Z. Physik* **65**, 575–88(1930).—The variation of resistance of absolutely pure Fe in a magnetic field is much larger than that of ordinary Fe and is free from hysteresis effects. Moreover this change parallels the magnetization and depends on the cryst. structure of the sample. It seems possible that Franks' theory (*C. A.* **24**, 4674, 5549) also holds for ferromagnetic substances in a strong field. E. B.

The variation of the metallic resistance in a strong magnetic field. N. H. FRANK. *Z. Physik* **64**, 650–6(1930); cf. *C. A.* **24**, 5549.—Sommerfelds' application of the Fermi statistics to the variation of metallic cond. in a magnetic field of small intensity leads to the relation: $d\rho/\rho = BH^2$ (ρ = resistance, H, magnetic field). These calcns. are generalized to include also strong fields and result in the formula: $d\rho/\rho = BH^2/(1 + CH^2)$, which leads to Sommerfelds' formula when H is small (compared with $\sqrt{1/C}$). Kapitzas' measurements are well represented by the new expression. E. B.

Measurements with the aid of liquid helium. IX. The supraconductivity of carbides and nitrides. W. MEISSNER AND H. FRANZ. *Z. Physik* **65**, 30–54(1930); cf. *C. A.* **24**, 5565.—The following compds. are supraconducting at the abs. temp. T: TiN(T 2.6 or 1.1), VN(T 1.3), ZrN(3.2), ZrN-TiN(3.0), TiC(1.1), WC(2.8), Mo_2C(2.4), MoC(7.7), TaC(9.2), CbC(10.1). The compds. which are not supraconducting are: VC, ScN, CdO, Mo_2O_5, WO_2. *Conclusions.*—The temp. of transition to supraconduction of a carbide or nitride is higher than that of the pure metal. Supraconduction is not restricted to a single crystal structure, but seems to be related to the smallest distance of 2 atoms, when a compd. is formed (*e. g.*, Ta 2.83×10^{-7} mm., TaC 3.17×10^{-7} mm.).
EGON BRETSCHER

Studies on the diffusion of metals in the solid state. I. SHINSUKE TANAKA AND CHICHIRO MATANO. *Mem. Coll. Sci. Kyoto Imp. Univ.* Ser. A, **13**, 343–51(1930).—A strip composed of alternate layers of Ag and Au deposited electrolytically was placed in a vacuum furnace and heated to 450° at the rate of 4° per min. Its resistance was measured every 5 min. and was found to increase sharply at 250°. X-ray powder photographs indicated the formation of an alloy. If the temp. is kept const. at 250°, the increase in resistance of the strip is given by the equation $R = Ae^{-\alpha/t}$ where R is resistance, t is time, A and α are consts.
MALCOLM DOLE

Strontium amalgams. G. DEVOTO AND E. RECCHIA. *Gazz. chim. ital.* **60**, 688–92 (1930).—The prepn. of Sr by electrolysis of $SrCl_2$ has been undertaken by various experimenters, but with only fair results. The yields obtained by the method of Neumann and Bergve (*C. A.* **8**, 2114), *i. e.*, with a eutectic mixt. of $SrCl_2$ and KCl at 750°, can be increased by replacing the Fe cathode with a Ni cathode, to which Sr adheres better, by substituting KBr for KCl, and by employing a temp. just below 800°. For prepg. the amalgams, electrolytic Sr and triple-distd. Hg were used. The amalgams with lesss than 2% (in atoms) of Sr were prepd. directly by electrolysis of satd. aq. $SrCl_2$ on a Hg cathode. The amalgams with higher Sr content were prepd. by heating Hg and Sr at 300° for 48 hrs. in a closed tube. Thermal analyses were made: (1) in the range from room temp. to the b. p. of Hg (with a ferro-constantin couple), and

(2) in the range —30° to —60° (with 3 thermocouples in ferro-constantin series). The amalgams were kept out of contact with air. Aside from the eutectic point, and the b. p. of Hg, no characteristic point was observed. But with a *differential method* which is described, a break in the %-temp. curve at 262° was observed. Comparative measurements with the corresponding break at 266° of Ca-Hg showed that the evolution of heat is 5–6 times as great with Ca-Hg as with Sr-Hg. In Sr amalgams the *compd.* is $SrHg_6$. A very slight and ill-defined break in the curve at 39° was observed, which may represent the $SrHg_{12}$ of Kerp (cf. *Z. anorg. Chem.* **17**, 284(1895)). In conjunction with other expts., the results show that the more electropos. the metal the more complex the compd., *viz.*, $MgHg_2$, $CaHg_6$, and $SrHg_6$, as with the alk. earth metal amalgams which pass from $LiHg_3$ to $CsHg_{10}$. This variation is probably related closely to the at. radii, which increase greatly from Li to Cs and from Mg to Ba. Moreover, the b. p increases in the amalgams, *viz.*, Hg-Ca 337° and Hg-Sr 390°. At room temp. the affinity for Hg increases with the at. wt., as can be calcd. from the potentials at 25° (cf. Devoto, *C. A.* **22**, 4347; **23**, 2626); Ca^{++}/Ca, $E_{298} = 2.895$ v.; Sr^{++}/Sr, $E_{298} = 2.94$ v.; Ba^{++}/Ba, $E_{298} = 2.96$ v., and from the e. m. f. values of the piles at 25° (cf. Danner, *C. A* **19**, 434): $SrHg_x$, $SrCl_2$ (0.1 *N*), HgCl, Hg $E_{298} = 2.024$ v., where x is approx. the same in each case. The difference in the activity of the $SrCl_2$ and $BaCl_2$ solns. is negligible

C. C. Davis

Some physicochemical studies of organometallic compounds. Henry Gilman, L. L. Heck and J. A. Leermakers. *Proc. Iowa Acad. Sci.* **36**, 270(1929).—The physicochem. properties such as mol. wt., cond. and absorption spectra were detd with a miscellany of organometallic compds. in connection with studies on their dissocn and their constitution. Also, their reactions toward O, N_2O and H (catalytic with Pt) were investigated for the same purpose as well as to test electronic structures proposed for the constitution of N_2O and organometallic compds.

W. G. Gaessler

Hydrochloric acid solutions of iodine monochloride. Frederick A. Philbrick *J. Chem. Soc.* 1930, 2254–60.—The form in which ICl exists in aq. HCl soln. can be detd. by the effect of its addn. on the chloride-ion concn. of HCl solns. To do this, the distribution coeff. of I between aq. ICl-HCl-KCl (from KIO_3, I, HCl, H_2O) and comparison solns. with equal HCl-KCl concn. is detd., by bringing them into equil. with the same I-CCl_4 soln. Then by substituting in: $D = (2.54a_1 + 1.35)/(2.54a_2 + 1.36)(a_1 + 0.54)/(a_2 + 0.54)$, (where a_1 and a_2 are the HCl concns. with the same chloride-ion concns. as the ICl solns., and D is the distribution coeff.) the change in the chloride ion concn. due to the ICl addn. is detd. It is thus shown that in HCl soln., ICl is a highly ionized electrolyte, while undissocd. ICl or any compd. of it with HCl does not exist in soln. These results confirm the view that the formation of electrovalencies is promoted by a large cation and a small anion. The app. (glass) used in detg the distribution coeffs. of I is so constructed that the I-CCl_4 is circulated through the 2 solns., each contained in a cylindrical bulb. These bulbs are so interconnected with tubing that the I-CCl_4 drops first through one and then through the other soln. A microtitration vessel for detg. the I (3 mg. of I to 0.1%) with $Na_2S_2O_3$ is described, and is so designed that the tip of a wt. buret is brought into contact with the liquid to be titrated.

J. Balozian

The conductivity of cod-liver oil. L. W. Butler. *Proc. Iowa Acad. Sci* **36**, 299–300(1929).—Expts. were made on the cond. of cod-liver oil under different conditions. These expts. were carried out in a cond. cell with brass plates placed in some instances about 0.003 in. apart and at other times at about 0.020 in. The temp. of the oil was raised to approx. 50° and allowed to drop slowly to 3° or 4° below zero, readings of the cond. being made at frequent intervals. The cond. decreased as the temp. was lowered, the decrease becoming very rapid at the lower temp. When the temp. was raised, the cond. increased, the cond.-temp. curves being approx. the same in the 2 cases. The general shape of all the cond.-temp. curves obtained with samples of different oils or with samples of the same oil under varying circumstances were the same, but the values of the conductivities varied widely. If the oil was exposed to the air for a short time, the cond. decreased slightly, but when exposed for about 24 hrs. the cond increased to nearly double its former value. Bubbling air through the oil at 90°, which destroys the vitamin A content, almost halved the cond. Expts. to det. whether the oil is photoelec. under the action of ultra-violet light gave neg. results. The sp. resistance of the oil appears to vary from 10^{10} ohms per cm. to 10^{13} ohms per cm. according to the brand of oil tested and its previous treatment.

W. G. Gaessler

Mechanical properties of surface energy. V. Ducceschi. *Kolloid-Z.* **54**, 13–7 (1931).—The spreading of camphor, menthol and thymol on water surfaces causes a propeller to rotate or exerts a measurable pressure. This mechanical effect resulting

from the two-dimensional scattering of mols. may be responsible in a special way for effects such as those in *muscle contraction.* ARTHUR FLEISCHER

A method for measuring wetting tension and several results. WALTER HALLER. *Kolloid-Z.* **54,** 7–13(1931); cf. *C. A.* **25,** 630.—The forward and reverse displacement velocities of a meniscus are measured when moving to equil. in a horizontal capillary; the liquid pressure is varied to make a series of detns. Extrapolation to 0 velocity gives the difference in liquid levels which is directly related to the wetting tension by the equation $\beta = \alpha - 2(h_r - h_v)d/r$, where β is the wetting tension, h_r is the height of capillary rise on the inward (reverse) movement or the height with complete wetting, h_v is the height on the outward movement or with incomplete wetting, α is the surface tension, d the d. of the liquid, and r the radius of the capillary. Wetting tensions on glass at 20° were detd. for the following liquids and are expressed in dynes/cm.: isoamyl alc. 22.7, heptyl acetate 23.9, petroleum 24.8, hexanol 25.6, benzyl alc. 37.0, lactic acid 38.5, aniline 39.7, acetophenone 40.6, glycol 43.9, water 50.5, glycerol 62.6. A hysteresis phenomenon appears in the measurements which is quite singular. Acetophenone leaves a very unstable film on the glass. Liquids like water, glycol, glycerol, and lactic acid leave stable films and on repeat measurements the curve shows the characteristics of a completely wetting liquid ($h_r - h_v = 0$). By coating the inner walls of the capillary with a film, wetting tensions on ceresin, nitrocellulose, gelatin, and acetylcellulose can be detd. Acetylcellulose films show a marked aging effect. Liquid mixts. and solns., especially of capillary-active substances, behave differently from pure liquids. Butanol in water lowers the surface tension but not the wetting tension on glass. When the surface tension is less than 51 dynes/cm. the soln. wets glass completely. The effect of a solute on the wetting tension depends on the nature of the adsorption film formed. With unstable films, there is no change in the wetting tension, but the wetting velocity is affected; with metastable films, there is a decrease in the wetting tension; with stable films, there is an increase in the wetting tension. Capillary-active substances with no effect on the surface tension of the soln. may cause a large effect on the wetting tension. Sugar solns. with 0.05% sugar concn. raise the wetting tension and give films that display vivid interference colors.

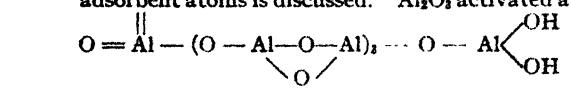
ARTHUR FLEISCHER

Studies in electrocapillarity. III. The surface tensions of solutions containing two surface-active solutes. J. A. V. BUTLER AND CHAS. OCKRENT. *J. Phys. Chem.* **34,** 2841–59(1930); cf. *C. A.* **24,** 5562.—Langmuir's theory of adsorption is applied to the simultaneous adsorption of two solutes from soln., and the surface tension effects in such solns. are evaluated. It is shown that in the absence of any interaction between mols. in the surface layer, the surface-tension lowering produced in the presence of a surface active substance at const. concn. c_1 by a second substance at concn. c_2 is $\Delta\gamma_2 = b_2 \log(1 + c_2)/a_2(1 + c_1/a_1)$, where the surface tension lowering of the first substance alone is given by Szyszkowski's equation: $\Delta\gamma_1 = b_1 \log(1 + c_1/a_1)$. Measurements were made of the surface-tensions at the air-soln. interface of aq. solns. of (1) EtOH and PrOH, (2) PrOH and PhOH, which agree well with these equations. A modified form of Szyszkowski's equation for highly active solutes is given and the same treatment is extended to solns. contg. two solutes. The electrocapillary curves of solns. contg. a wide range of concns. of caffeine and phenol were detd. The surface tension lowerings are in reasonable agreement with the modified theory for highly active solutes. The electrocapillary curves of mixed solns. of Na cinnamate and Na *o*-toluate were detd. The crit. concn. of Na cinnamate in the presence of which the effect of 0.05 *M* Na *o*-toluate is first observable was found. The effect of Na *o*-toluate on the surface tension of Na cinnamate solns. is less than predicted by the theory and the deviations are ascribed to the effect of the elec. charges of the adsorbed cinnamate ions hindering the adsorption of further ions of the same sign. H. M. STARK

The relation between the balloelectric phenomenon and the potential difference at the interface gas/solution. A. FRUMKIN AND A. OBRUCHEVA. *Kolloid-Z.* **54,** 2–7 (1931); cf. *C. A.* **19,** 3046; **21,** 201.—The balloelec. effect (B) detd. by Christiansen (cf. *C. A.* **7,** 3069; **11,** 2427; **14,** 490) for solns. contg. a non-capillary-active electrolyte and a capillary-active nonelectrolyte, recalcd. on the basis of the value of a 1 *M* C_2H_5OH and 0.05 *M* NaCl soln. equal to 50, were compared with data on the potential difference (e) at the interface for the same solns. Detn. of B and e in 0.5 *M* KCl soln. with varying concn. of EtOAc, CCl_3COOH, or propionic acid show that both decrease with decrease in nonelectrolyte concn., with their ratio almost const. The B effect is very greatly dependent on the electrolyte concn. while e is practically independent except at very high, concns. where the salting out effect appears. Salts of halogenated fatty acids behave like the free acids, yielding a neg. B effect. Other capillary-active electrolytes

such as substituted amine salts (*e. g.*, $C_6H_5NH_3.HCl$) show an effect opposite in sign to that of the free base. Phenols on the addn. of small quantities of alkali show pos. effect, whereas the free phenols show a neg. effect. ARTHUR FLEISCHER

Potential differences at air-liquid interfaces. JOHN W. WILLIAMS AND V. A. VIGFUSSON. *J. Phys. Chem.* **35**, 345–53(1931).—A discussion of methods of measuring p. ds. perpendicular to the surface at air-liquid interfaces. MALCOLM DOLE



Studies on electrokinetic potentials. VI. Electrical phenomena at interfaces. HENRY B. BULL AND ROSS AIKEN GORTNER. *J. Phys. Chem.* **35**, 309–30(1931).—The ζ-potential and surface cond. at a cellulose interface were measured for aq. solns. of KCl, NaCl, $MgCl_2$, $CaCl_2$, K_2CO_3, K_2SO_4, K_3PO_4 and $ThCl_4$ over a concn. range up to approx. 0.001 *N*. The ζ-potential decreases as the concn. increases due probably to a decrease in the thickness of the double layer although the charge on the particle may actually increase. MALCOLM DOLE

Influence of size, shape and conductivity on cataphoretic mobility and its biological significance. HAROLD A. ABRAMSON. *J. Phys. Chem.* **35**, 289–308(1931); cf. *C. A.* **24**, 5568.—By suspending glass, quartz or other particles in a protein soln., both particles and flat surface of the cataphoresis cell can be coated with the same substance, fulfilling the condition of chem. similarity of glass and particle surface. Under these conditions, the ratio of cataphoretic to electroösmotic mobility was found to be one. The mobility of mammalian red cells at p_H 7.35 in *M*/15 phosphate buffer varied from 0.55μ/sec./v./cm. for rabbit to 1.65μ/sec./v./cm. for the dog. FRANK URBAN

Electrophoresis and the diffuse ionic layer. MELVIN MOONEY. *J. Phys. Chem.* **35**, 331–44(1931).—The theory of the diffuse ionic layer and its influence on the electrophoresis of a sphere are outlined, and a theoretical equation for the limiting slope of the mobility-curvature curve is given. Equations are given for *surface charge* and *surface cond.* Various anomalous effects in cataphoresis suggest a plastic adsorbed layer which seems to have a profound effect on the electrokinetic potential. The *Debye-Hückel cataphoresis equation* is limited to conditions in which the colloidal particle is much smaller than its diffuse ionic layer. FRANK URBAN

Density, surface tension and adsorption in the water-ammonia system at 20°. H. H. KING, J. LOWE HALL AND GLEN C. WARE. *J. Am. Chem. Soc.* **52**, 3128–35(1930); cf. *C. A.* **22**, 2092.—The surface tension and d. of water-NH_3 were detd. (without transferring the liquid) by the use of a special pycnometer having a capillary side tube. Very complete data are given for the range of concns. of NH_3 from 50 to 100%. Observed surface-tension values agree well with calcd. values except in the middle region, where a depression conforms to Worley's rule (*C. A.* **8**, 1369) for perfectly miscible liquids. The relation of this deviation to adsorption is discussed. The surface tension of liquid NH_3 at 0°, 10° and 20° was accurately detd. By the Ramsey-Shields method used the mol. wt. of liquid NH_3 at 0–20° was found to be 24.5. An equil. system corresponding approx. to $(NH_3)_2$ (60%) $\rightleftharpoons$ 2 NH_3 (40%) is suggested. A. L. J.

The chemical theory of adsorption phenomena. E. V. ALEKSEEVSKII. *J. Russ. Phys.-Chem. Soc.* **62**, 817–26(1930).—Adsorption due to secondary valencies of the adsorbent atoms is discussed. Al_2O_3 activated at 400° is considered to have the structure

which corresponds to a water content of 4.2%. The addn. of H_2O to the "unsatd." Al atom renders it inactive. This explains why nonelectrolytes such as alcs. are readily adsorbed from the vapor phase but not from aq. soln. Heating to higher temps. transforms the chain structure into a closed ring in which all the Al atoms are inactive. B. SOYENKOFF

Poisoning effects of water vapor on the adsorption of carbon dioxide by manganese dioxide. H. W. FOOTE AND J. K. DIXON. *J. Am. Chem. Soc.* **53**, 55–8(1930); cf. *C. A.* **24**, 3937.—The adsorption isotherms at 25° of CO_2 on MnO_2 with and without adsorbed water were detd. and the corresponding behaviors of CO toward MnO_2 with and without adsorbed water were qualitatively detd. The adsorption of CO_2 on MnO_2 is reversible. Water reduces the adsorption markedly, the results indicating the presence of active adsorption patches on the oxide surface, since the first portion of water adsorbed results in the greatest lowering of the CO_2 adsorbed. Adsorption of CO on MnO_2 is more complicated and is highly irreversible, but the presence of water has an effect similar to its effect on the adsorption of CO_2. With CO_2 when approx. 35% of the surface was covered with water the amt. of CO_2 adsorbed was reduced by 50%. J. W. SIMPLEY

The activation and sorption of the rare gases by palladium (argon, neon, helium).

M. E. KLARMANN. *Z. Physik* **65**, 358–84(1930).—Suitable heat treatment activates Pd ribbon in such a way that 1 vol. of Pd adsorbs the rare gases to the following extent: Ne 446 vols., A 319 vols. The increase of resistance amounts in the first case to 33%, in the second to 24%. Adsorption of He is demonstrated, but quant. data are not given. EGON BRETSCHER

Investigation on the influence of adsorbed gases on the high-frequency resistance of platinum wire. HANS DOBRETSBERGER. *Z. Physik* **65**, 334–57(1930).—A short-wave oscillator is coupled with a resonance circuit, contg. the wire whose resistance is to be measured or a resistance of known value. An indicator circuit measures the energy of the resonance circuit by compensation. The resistance of the wire is detd. in high vacuum and after it has been charged with gases. *Results.*—It is possible to study gas adsorption by means of the skin effect. Pt adsorbs on the surface N_2 and CO_2 as shown by the increase of the high-frequency resistance, and it is found that the process is reversible. H_2 is adsorbed (as shown by the variation of the high-frequency resistance) and absorbed as well (as shown by the change of resistance for continuous current). EGON BRETSCHER

The effect of disintegration of charcoal on the adsorption of fatty acids. B. BRUNS. *Kolloid-Z.* **54**, 33–5(1931).—Unactivated, pure sugar charcoal showed the same reversal of Traube's rule as found by Dubinin (cf. *C. A.* **23**, 1549) with a HNO_3-treated charcoal. After grinding, the charcoal obeyed the rule except with HCOOH. The increase in adsorption increases with increase in the no. of C atoms in the fatty acid. The reversal of Traube's rule depends on the presence of pores which are not accessible to compds. with great mol. vols. ARTHUR FLEISCHER

The nomenclature of atmospheric disperse systems. HANS GRIMM. *Kolloid-Z.* **54**, 1–2(1931).—Inconsistencies are pointed out in the nomenclature applied in German literature to disperse systems with air as the continuous dispersing phase. A. F.

Magnetic properties of thin cobalt films, electrolytically deposited. E. P. T. TYNDALL AND W. W. WERTZBAUGHER. *Proc. Iowa Acad. Sci.* **36**, 297(1929).—Initial magnetization curves and hysteresis loops of Co films from 40 to 100 millimicrons thick show the same general characteristics as Fe films (*C. A.* **22**, 1897) of the same range of thickness. The sp. properties, however, depend largely on the acidity of the electrolyte. The linear relation between thickness and reciprocal of coercive force discovered for Fe films is not in general true for Co, though it is approximated in some series of films. W. G. GAESSLER

Diffusion of electrolytes, nonelectrolytes and colloidal electrolytes. JAMES W. MCBAIN AND TSUN H. LIU. *J. Am. Chem. Soc.* **53**, 59–74(1930).—The Northrop diffusion cell with diaphragm of sintered glass was used to det. rates of diffusion, giving results reproducible within a few tenths of a percent in a time relatively short as compared with the laborious classical methods. Diffusion coeffs. for various concns. of KCl at 25° into H_2O and of K laurate into H_2O and into less concd. solns. of K laurate at 25° are given. The results for a number of electrolytes and for soap were found to be independent of the nature and porosity of the diaphragm. The Nernst equation for electrolytes at great diln. and the Einstein equation for uncharged spherical particles are generalized in the equation $D = \frac{iRT}{\text{sum of resistances}} = \frac{iRT}{\Sigma(1/U_m)}$, where $1/U_m$ is the resistance to movement of a particular species. The predominant influence is the value of the van't Hoff i factor. The data for sugar solns. show that the viscosity contributed by the dissolved substance is not that which dets. the rate of diffusion. The diffusion column of one substance may by the bombardment of its mols. accelerate, retard or even reverse the diffusion of another substance. J. W. SHIPLEY

Liquid ammonia as a lyophilic dispersion medium. ROBERT TAFT. *J. Phys. Chem.* 34, 2792–2800(1930); cf. *C. A.* **24**, 1563.—Samples of various substances of 0.1 g. were placed in tubes contg. 10 cc. anhyd. NH_3, the tubes sealed off and kept in liquid NH_3 bath for 48 hrs. Observations for dispersion were made while the substance was at the temp. of boiling liquid NH_3 and also at room temp. Dextrin, cellulose acetate, inulin, glycogen and the nitrocottons dispersed well in liquid NH_3 at its b. p. Proteins and related substances did not disperse, except zein, gliadin, nucleic acid, proteose, peptone and bacto-peptone. Gums and resins dispersed poorly. Most marked dispersion in this class was that of gamboge, ammoniac gum and benzoin gum. All dyes tested showed some soly. but in no case was it in excess of 1%. Soaps were not dispersed by liquid NH_3. The author discusses the probability that these substances are in the colloidal state when dispersed. Also Ostwald's view that Na and sulfur are colloidally dispersed in liquid NH_3 is discussed. H. M. STARK

Photometric measurements of the concentration and dispersity in colloidal solutions. II. TORSTEN THORELL. *Kolloid-Z.* **54**, 58–66(1931); cf. *C. A.* **25**, 876.—The dispersity quotient (DQ) is defined as the ratio of the consts. defined by the equation $K = (1/d)\lg(I_0/I)$ and detd. at a short and a long wave length. In the equation, d is the thickness of soln. layer, I_0 is the incident intensity, and I is the emerging light intensity. Theoretically, DQ is a const. equal to 5.7 at very high dispersions up to 35$\mu\mu$, in the region in which Rayleigh's law is valid. From 35 to 75$\mu\mu$ particle sizes decreases almost linearly to a value of 1, which is the lower limit of its value. DQ is easy to measure when light intensities at two separated wave lengths are used. It is independent of the concn. It may be used as a dispersity control for the reproduction of sols. By the use of standard curves it is possible to det. concn. in sols with unknown dispersities. It makes it possible to det. abs. particle sizes without knowing the concn. of the dispersed phase. Time measurements of the flocculation of mastic sol by $CaCl_2$ and Fe_2O_3 sol by Na_2SO_4 by DQ measurements give a curve of the type $100(K_t - K_0)/K_0 = qt^m$. The aging process of a mastic sol shows a similar curve. ARTHUR FLEISCHER

Preparation of water-soluble colloidal mercury. A. F. GERASIMOV AND B. M. KOZUIREV. *J. Russ. Phys.-Chem. Soc.* **62**, 833–8(1930).—To 30 cc. Paal's mixt. (cf. *C. A.* **23**, 3840) is added 24 cc. glacial AcOH, the whole heated on a water bath until it no longer smells of H_2S (or a few min. if no H_2S is present) and a soln. of 0.375 g. $HgCl_2$ in water is added drop by drop. The colloid is pptd. with Na_2CO_3, washed with water at least 4 times and redissolved on addn. of NaOH. The soln., when evapd. on a water bath, yields a black powder contg. 27.6% Hg. Its 1% soln. is not affected by air and can therefore be preserved indefinitely. The colloid particles are negatively charged. In the above prepn., the protein mixt. itself (mainly its diffusible components) acts as the reducing agent. AcOH hinders the reduction; on the other hand, it increases the stability of the resulting sols. The amt. of NaOH used in redissolving the colloid should be just sufficient to produce a clear soln.; an excess of the alkali will cause a partial pptn. when the soln. is evapd. The sol is pptd. by AcOH, but it dissolves in excess. In acid soln., the coagulating power of the electrolytes increases to a greater extent with the valence of the cation than with that of the anion. In alk. soln. the cation is again much more important, satd. KCl and K_2SO_4 producing only a partial pptn., while small concns. of $AlCl_3$ completely coagulate the sol. The chlorides in general, render the alk. sol more resistant toward AcOH. B. SOYENKOFF

Preparation of water-soluble colloidal antimony. A. F. GERASIMOV AND I. S. MOROZOV. *J. Russ. Phys.-Chem. Soc.* **62**, 827–32(1930).—Two methods are suggested. (1) A mixt. of 24 cc. glacial AcOH and 30 cc. Paal's protein mixt. is warmed for 10 min. on the water bath; 3 cc. of $SbCl_3$ soln. (14.69 g. $SbCl_3$ + 14 cc. glacial AcOH + 14.4 g. tartaric acid + 25 cc. H_2O) is then added, followed by 4.5 cc. of 10% H_3PO_2 soln. Heating is continued until the mixt. is dark colored (15–20 min.). On cooling, the colloid is pptd. with Na_2CO_3 soln., washed and dissolved in H_2O on addn. of 2–3 drops 20% NaOH. The soln. is evapd. on the water bath, a partial vacuum being applied, and H_2 is passed through. (2) To 54 cc. of acid protein soln. (24 cc. glacial AcOH + 30 cc. Paal's mixt.) is added 7 cc. glacial AcOH, and the whole warmed for 10 min. Next are added 20 cc. of 5% potassium antimonyl tartrate, 4 cc. of 10% H_3PO_2 and, drop by drop, 0.5 cc. of HCl of sp. gr. 1.19. The heating is continued for about 10 min. (until the color deepens to dark brown). The remainder of the procedure is similar to (1). Glistening black powder is obtained contg. 39% Sb, 99.9% of which is in the free state. The powder dissolves rapidly in water, yielding a negatively charged sol of dark-red color. It is advisable to fractionate Paal's mixt. by adding a small quantity of glacial AcOH and filtering the ppt., and to use the filtrate in preparing colloid Sb. Paal's mixt. that has been aged is preferable to a freshly prepd. sample. The reduction process requires the presence of HCl or some other strong acid, an excess of HCl, however, will redissolve metallic Sb. The sol should be kept in a closed container, since atm. O_2 decolorizes it. The powder is very stable. B. SOYENKOFF

Preparation of water-soluble colloidal copper. A. F. GERASIMOV AND G. P. MARVEEV. *J. Russ. Phys.-Chem. Soc.* **62**, 839–42(1930).—To 30 cc. of Paal's mixt. is added 27 cc. glacial AcOH, the whole heated for 4–5 min. on the water bath, then 4 cc. of 15.68% $CuSO_4$ introduced, again heated for 4–5 min., about 5 cc. of 10% H_3PO_2 added and the heating continued for 5–6 min. On cooling the colloidal Cu is pptd. completely with Na_2CO_3 soln., washed 3–4 times and redissolved in H_2O on addn. of a few drops of NaOH soln. The resulting sol, when evapd. on the water bath, yields a water sol. powder contg. 25% Cu. The protein mixt. used in the above prepn. should be "aged" for 2 months in order to free it from H_2S. BASIL C. SOYENKOFF

The effect of pressures up to 17,000 atmospheres upon some colloidal suspensions. ROBERT WILSON AND THOS. C. POULTER. *Proc. Iowa Acad. Sci.* **36**, 295–6(1929).—Colloidal $Fe(OH)_3$ was found to be pptd. immediately, when subjected to pressures of 300 atm. or above. When subjected to pressures of much less than 300 atm. pptn. was a little slower and pressures of as low as 100 atm., were found to ppt. colloidal $Fe(OH)_3$ completely within about 30 min. Colloidal S is pptd. very little by pressures of less than 9000 atm. But the pptn. is rather rapid and complete, when pressures as high as 17,000 atm. are used. Colloidal Ag is pptd. very slightly by pressures much below 9000 atm. But it is completely pptd. within a few min. by pressures of 17,000 atm. Prussian blue requires a pressure of approx. 2000 atm. or above for immediate and complete pptn. Red colloidal Au prepd. by the tannin method, is readily pptd. by pressures above 2000 atm. Of the colloidal suspensions studied Mo blue was the only one not completely pptd. by pressures above 9000 atm., if the colloid is allowed to remain under pressure from several min. to a half hr. Mo blue showed some color change not noticed in any of the other suspensions studied. Samples subjected to pressures of 2000 to 9000 atm. changed from blue to green and showed very little pptn. However, at pressures above 9000 atm. the suspension retained its original color and was slightly pptd. Mo blue was the only one remaining in the suspended state after the pressure had been above that necessary for the formation of ice six, which is between 8000 and 9000 atm. W. G. GAESSLER

The precipitate rule in the system: cellulose-cupric ammonium hydroxide-sodium hydroxide. I. SAKURADA. *Kolloid-Z.* **54**, 43–6(1931).—With increase in the quantity of ppt., the Cu-alkali-cellulose increases to a max. and then decreases. If the comparison is made in solns. with the same proportion of ppt. combined with Cu, Ostwald's pptn. rule is followed. The cellulose is changed by a topochem. reaction to a compd. with different soly. characteristics. ARTHUR FLEISCHER

Ion exchange on the surface of colloidal platinum. S. W. PENNYCUICK. *Kolloid-Z* 54, 21–32(1931); cf. *C. A.* **22**, 709, 2305, 4306; **23**, 3389.—Ion exchange on unfiltered Pt sol with 0.13 to 0.15 g. Pt/l. and prepd. by sputtering in cond. water was detd. in HCl, KCl, NaCl, $BaCl_2$, $CaCl_2$, $AlCl_3$, $FeCl_3$, $AgNO_3$, KCN solns. up to 0.0014 *N* by measurement of the cond. at 18°. The results with HCl show that no acid is adsorbed and that chloride ion is not adsorbed. The ion exchange is cation of the salt for H ion present on the Pt surface. Ba and Ca show very small effects while the exchange with Na is within the exptl. error. $AgNO_3$ shows a high exchange despite the low value at which coagulation occurs. The expts. show that there is no sudden change at the coagulation point. That ionic exchange is a cause of coagulation is seen from the $\sqrt{c}$ concn. curves. The ionic exchange is equiv. except where hydrolysis occurs. The results with KCN show the importance of hydrolysis in ion exchange. A. F.

The flocculation of ferric hydroxide sols by various electrolytes and the Schulze-Hardy law. AUGUSTIN BOUTARIC AND JEAN BOUCHARD. *Compt. rend.* **191**, 613–5 (1930).—A $Fe(OH)_3$ sol of concn. corresponding to 1.28 g. Fe_2O_3 per l. was prepd. by hydrolysis of $FeCl_3$. The mg. equiv. required to cause flocculation of one l. when added as a *N* soln. of K salt (except where noted otherwise) of anions was found to be as follows: Cl^- (80.0), I^-(77.8), Br^-(73.6), NO_3^-(73.6), ClO_3^-(72.8), ClO_4^-(72.8), CNS^-(24.8), MnO_4^- (0.0), $CH_3CO_2^-$(6.0), $H_2PO_2^-$(5.8), F^-(1.24), OH^-(0.36), CN^-(0.35), $(Na)_2S_2O_3^-$ (0.75), $(Na)HSO_2^-$(0.72), CO_3^{--}(0.36), SO_4^{--}(0.36), CrO_4^{--}(0.35), PO_4^{---}(0.36), $CrH(O_4)^{--}$ (0.34). The exceptions to the rule of Schulze-Hardy in the above list indicate that other factors than valence must be considered and adsorption is suggested. The results in this paper do not agree well with those obtained by Freundlich (*Z. physik. Chem.* 44, 131(1903)), who used other than K salts in many cases. A. L. T.

The coagulation of methylene blue with mercuric chloride. N. N. ANDRONIKOVA. *Kolloid Z.* 54, 82–4(1931).—Na, K, Mg, Ca, Ba, Fe, Al and Mn chlorides do not coagulate methylene blue solns. Fifty cc. of soln. contg. 0.05 g. of methylene blue is first coagulated on the addn. of 0.06 g. $HgCl_2$. The color of the ppt. depends on the amt. of $HgCl_2$ varying from blue to violet. The $HgCl_2$ in the ppt. reaches a max. with increasing Cl_2 in soln. and then decreases through a min. The coagulation is reversible; heat or dilu. causes soln. of the ppt. KSCN shows the same behavior with methylene blue. ARTHUR FLEISCHER

Preparation and study of some hydroxide jellies. SATYA PRAKASH AND N. R. DHAR. *J. Indian Chem. Soc.* **7**, 591–606(1930); cf. *C. A.* **22**, 1080; **24**, 4977.—The jellies of $Fe(OH)_3$, $Cr(OH)_3$ and $Al(OH)_3$ were obtained by treating the metallic chlorides or nitrates with NaOAc, $(NH_4)_2SO_4$ and NH_3 in suitable concns., the details of which were investigated in a comparative way by varying the concn. of different jelly-forming constituents. The jelly of $Zr(OH)_4$ was obtained by the addn. of NaOAc only to Zr-

$(NO_3)_4$ soln. The addn. of SO_4 ions favored the formation of this jelly; but addn. of NH_3 was not necessary. The jelly of $Sn(OH)_4$ was obtained by the addn. of NaOAc and $(NH_4)_2SO_4$ to $SnCl_4$ soln. No addn. of NH_3 was necessary unless there was much free acid in the $SnCl_4$ soln. The mechanism of the formation of these hydroxide jellies is explained on the assumption of the formation of colloidal hydroxides by the action of NaOAc on the metallic salts, which are stabilized by the adsorption of metallic and H ions. The function of NH_3 is to reduce the H ions to such an extent as to make the system liable to coagulation by $(NH_4)_2SO_4$. The $(NH_4)_2SO_4$ gradually reduces the pos. charge of the colloidal particles and the system thereby becomes more viscous and hydrated, and finally the jellies are obtained. All of these jellies were obtained in acid medium. A comparative study of H-ion concns. of the jelly-forming systems showed that the jellies of different metals cannot be obtained at the same H-ion concn. The jellies most readily obtained are of those metals, as Zr and Sn, that on the addn. of jelly-forming constituents give a medium of greatest H-ion concns. These jellies are, however, less stable than those obtained in a medium of less H-ion concns., such as Al, Cr and Fe. The hydroxide jellies of Ni, Co, Cu, Cd, Hg and Th could not be obtained by the methods used for Fe, Cr, etc. It appears that in the case of these substances, the agglomeration tendency of the particles is more pronounced than the hydration tendency. W. C. FERNELIUS

Hydrogels. X. Manganese dioxide hydrate. A. SIMON AND F. FEHER. *Kolloid-Z.* **54**, 49–58(1931); cf. *C. A* **23**, 1334; **24**, 1782.—Isobaric vapor pressure curves at 10 mm. were detd. from 50° to 400° for 6 differently prepd. MnO_2 gels with H_2O content varying from 0.39 to 0.53 mol. All of the curves were continuous and indicated the absence of a definite hydrate. MnO_2 behaves very much like PbO_2. Peptization expts. show MnO_2 to be an irreversible gel that ages very rapidly. A. F.

The influence of volume in swelling. D. JORDAN LLOYD. *Kolloid-Z.* **54**, 16–9 (1931); cf. *C. A.* **23**, 5082.—The swelling of gelatin at 0° in NaOH solns. up to p_H of 13 was detd. At each p_H a given quantity of gelatin was treated with 3 different vols. of soln. The detns. fall on a single curve, showing that swelling is independent of the vol. of soln. when hydrolysis is repressed. The swelling effect in NaCl solns. to 1 *M* at 0°, 18° and 25° is independent of the vol. of soln. used. Salts such as $NaNO_3$ which cause a rapid soln. of the gelatin show a time-swelling curve that is S-shaped. ARTHUR FLEISCHER

Blocking effect of membranes. G. H. BISHOP, FRANK URBAN AND H. L. WHITE. *J. Phys. Chem.* **35**, 137–43(1931).—Blocking of membranes may be due to differences in streaming potentials of individual membrane capillaries. The capillary having the higher streaming potential will transport water electroösmotically through the capillary of low streaming potential. Cellophane membranes treated with $ThCl_4$ showed markedly decreased blocking, presumably due to lower streaming potential values. Preliminary detns. of streaming potentials with Pyrex capillaries of less than 50μ radius indicate a size-difference in streaming potential. FRANK URBAN

A photomicrographic study of Liesegang rings. SUZANNE VEIL. *Compt. rend.* 191, 611–2(1930).—A gelatin soln. impregnated with $K_2Cr_2O_7$ was spread thin on a glass plate and a single drop of $AgNO_3$ soln. placed on this. The Liesegang rings that developed were examd. photomicrographically. The principal rings were found to be so spaced that the square root of the distance between successive rings varied in a simple arithmetic series. This quantity when plotted against the numerical order fell closely on a straight line. A. LLOYD TAYLOR

The optical properties of protein sols and the influence of neutral salts and p_H. N. YERMOLENKO. *Kolloid-Z.* **54**, 66–73(1931).—Index of refraction (n) measurements of 1 and 2% gelatin solns. at 25° showed no change with time. A 2.5% soln. heated to various temps., and rapidly cooled to 25° showed the same value of n under all the conditions. The n does not seem to be a function of the condition of aggregation of the colloid. The same results were obtained with a glutin (fish glue) soln. Gelatin solns. from 0.59 to 2.5% treated with H_2O, *N* NaCl and *N* $CaCl_2$ gave equations $K = (n - n_1)/c$ with the consts. H_2O 0.00167, NaCl 0.00275 and $CaCl_2$ 0.00328. Measurements on a 1% gelatin at p_H from 1.22 to 10.9 showed very little effect on n. Glutin solns. in 0.5 *N* solns. of Li, K, Na, Mg, Ca, Ba, Al and Fe chlorides showed a const. n after correction for the salt was made. ARTHUR FLEISCHER

The preparation of colloids by the method of condensation of molecular rays. N. TOMASHEVSKII. *Kolloid-Z.* **54**, 79–81(1931); cf. Semenov and Shalnikov, *C. A.* **20**, 3622.—Na sol in ether was stable for a month and showed an absorption spectrum from 6238 to 4696 A. U. with the violet end polarized. The xylene sol was stable for 12–20 hrs.; the benzene sol had a dirty-violet color and was stable for 3 days; the

hexane sol was very much like the benzene sol and was difficult to prepare. K sol in ether had a blue color and was stable for 2 months; in xylene it had a green-blue color and was stable for 10 days. Rb and Cs sols in ether had a dark-blue color and were stable only for 20 min. Hg in H_2O and Cd in ether were of gray color and stable for 20 hrs. The particle dimensions are greater than mol. ARTHUR FLEISCHER

The action of polyhydroxy compounds in the synthesis of hydrosols. IV. Sugars. A. V. DUMANSKII AND L. G. KRAPIVINA. *J. Russ. Phys.-Chem. Soc.* **62**, 1713–21(1930); *Kolloid-Z.* **54**, 73–9(1931); cf. *C. A.* **24**, 3939.—The results of the systems: NaOH–$FeCl_3$–sugar are effectively represented by the triangle plot. The order for decreasing effectiveness of peptization is lactose, levulose, maltose, galactose, glucose, sucrose and raffinose. The property depends on the structure of the sugar. ARTHUR FLEISCHER

A theory of solubility. P. A. BOND. *Proc. Iowa Acad. Sci.* **36**, 262–3(1929).—The theory supposes that soly. is due to 2 forces: first, one that tends to arrange substances into the lattice forms that they would have in the solid state, second, to thermal forces tending to break up such lattice forms. The fundamental assumption is made that lattice forms consisting of combinations of solvent and solute must tend to form where soln. exists. It is shown that an ideal soln. based on tendencies to form lattice structures between solute and solvent equal to those of the original solute and solvent conforms to Raoult's law. Double layers, complex ions, hydrolysis, etc., find ready explanation by the theory. W. G. GAESSLER

The state of distribution of lichosan in dissolved and solid states. HANS PRINGSHEIM AND CURT LAMM. *Kolloid-Z.* **54**, 36–42(1931); cf. *C. A.* **23**, 376, 377.—Cryoscopic, b. p. and viscosity measurements and fluoroscopic tests were made on lichosan pptd. from soln. with alc. Lichosan prepd. by the hydrolysis of lichenin triacetate in acetone or chloroform, on cold pptn. shows an aggregation of 5 mols. of $C_6H_{10}O_5$; hot pptn. shows an initial aggregation of 3 mols., which increases on aging of the soln. Fluoroscopically, there is a decided difference between aged and unaged samples; the smaller mol. aggregate shows the greater fluorescence. Lichosan prepd. by the hydrolysis of lichenin in glycerol shows a mol. wt. of about 825 when cold-pptd. and values from 200 to 1290 for hot pptn., the value depending on the treatment of the soln. ARTHUR FLEISCHER

The mobility of the perchlorate ion in methanol. E. D. COPLEY AND (SIR) HAROLD HARTLEY. *J. Chem. Soc.* **1930**, 2488–91.—The elec. conductivities of 0.0001–0.002 *N* LiClO$_4$, NaClO$_4$ and AgClO$_4$ solns. in MeOH are detd. at 25°, from resistance measurements by the method of Frazer and Hartley (*C. A.* **20**, 136). The detd. cond. values agree with those calcd. from: $\Lambda_c = \Lambda_0 - x\sqrt{c}$ (where, Λ_0 is the cond. at infinite dilu., and x is a const.), excepting in the more dil. AgClO$_4$ solns. The calcd. (from the Debye-Hückel-Onsager equation: $x = 0.957\ \Lambda_0 + 158.1$) and observed values of x agree well. The mean value for the ClO_4^- mobility (detd. by subtracting the mobilities of the resp. cations found by F. and H., from the Λ_0 values) given by LiClO$_4$ and NaClO$_4$ is 70.85, and the corrected value for Ag^+ is 50.3, in MeOH at 25°. The high mobility of the complex ClO_4 ion is explained by assuming that it is less solvated than other simpler ions, because of the weaker elec. field in its vicinity. J. B.

The conductivity of some uni-univalent salts in ethyl alcohol. E. D. COPLEY, D. M. MURRAY-RUST AND (SIR) HAROLD HARTLEY. *J. Chem. Soc.* **1930**, 2492–8.—The conductivities of LiCl, LiNO$_3$, AgNO$_3$, NaBr, KI, RbI, LiClO$_4$, NaClO$_4$ and AgClO$_4$, and the mobility of the ClO_4 ion are detd. in 0.0001–0.002 *N* EtOH solns. at 25°, a method being developed for *prepg. cond. EtOH*. The Λ_0 values for the perchlorates show that in EtOH the ClO_4 ion has a greater mobility than the other anions, indicating that it is less solvated. The graphs of the results show, in agreement with the theory for strong electrolytes, that the decrease in cond. is proportional to the square root of the equiv. concn. To prep. cond. EtOH (with sp. cond. = 0.003×10^{-6} mhos) first most of the H_2O in the alc. is removed by refluxing for 24 hrs. with freshly fired lime; then it is distd. through a long fractionating column; the last traces of H_2O are removed by distn. from Al ethoxide (made by warming the lime-dried alc. with Al amalgam for some hrs.), and finally volatile impurities are removed by refluxing in a current of pure air in the presence of CuSO$_4$ (anhyd.). J. BALOZIAN

Application of the Debye theory to binary liquid mixtures. III. Derivatives of ammonia. JOHN M. FOGELBERG AND JOHN W. WILLIAMS. *Physik. Z.* **32**, 27–31 (1931). Mol. fractions, densities, dielec. consts., mol. polarization of the solns., P_{12}, and mol. polarization of the solute, P_2, are tabulated for benzene solns. of *o*-chloroaniline, *m*-chloroaniline, *p*-chloroaniline, dimethylaniline, methylaniline, triethylamine and diethylamine. Data for these and other ammonia derivs. are tabulated with the

detd. dipole moments. The data are discussed from the viewpoint of stereochemistry. It is shown that the dipole moments of such mols. can, in general, be computed only if account is taken of the position in space of the characteristic vectors of the groups on the basis of (1) the stereochemistry of the atoms which constitute the groups, and (2) the attraction and repulsion between the groups. WILLIAM E. VAUGHAN

The partial specific volume of potassium octoate in aqueous solution. DAVID G. DAVIES AND CHARLES R. BURY. *J. Chem. Soc.* 1930, 2263–7.—The d_{25}^{4} of various aq. K octoate solns. (0–28%) are detd. by the method of Hartley and Barrett (*C. A.* 5, 2996), and the partial sp. vols. calcd. by Hildebrand's method ("*Solubility*," 1924, 64). The abrupt change in the slope of the d.-concn. curve at 6–9% of soap is attributed to the existence of a crit. concn. for micelles and is far less marked at higher temps. This shows that the tendency to form micelles decreases with increasing temp. The curve of the partial sp. vol. of K octoate against % K octoate resembles very closely that of butyric acid (Grindley and Bury, *C. A.* 23, 3616); the rapid rise indicates the crit. concn. for micelles and occurs at 7.5–8.0% of soap. This crit concn. decreases with increasing temp. J. BALOZIAN

The calculation of activity coefficients from solubility measurements. II. Thallous iodate. CECIL W. DAVIES *J. Chem. Soc.* 1930, 2410–21.—The activity coeffs. of dil. aq. $TlIO_3$ solns. in the presence of uni-univalent (KCl, NaCl, KNO_3, NaNO) and uni-bivalent (K_2SO_4, Na_2SO_4) salts are calcd. (*C. A.* 25, 949); the undissocd. parts of the salts present are taken into consideration. The results of LaMer and Goldman (*C. A.* 23, 5085) for $TlIO_3$ at 25° are used. If the incomplete dissocn. of the salt concerned is taken into consideration, the activity coeffs. of $TlIO_3$ lose all abnormality. In uni-univalent salt solns. sp. influences are not appreciable at concns. below 0.1 *N*, and with multivalent electrolytes not below 0.05 *N*. In its limiting form the Debye-Huckel equation for the activity coeff. of a sparingly sol. uni-univalent salt is $-\log f = A(\mu)^{1/2}$ (where, f = the activity coeff., μ = the ionic strength, and A = a const. (0.47 is obtained by D. for dil. $TlIO_3$ solns.)). The value of A varies from salt to salt, but is always less than Debye-Huckel's value of 0.50. Bronsted's theory of the sp. interaction of ions (*C. A.* 16, 2057; 18, 779) is not supported by the soly. data for $TlIO_3$. The value of the dissocn. const. of the $MgIO_3^+$ ion is 0.19. **III. The unsymmetrical valence type.** *Ibid* 2421–6.—The calcns. of the preceding paper are extended to multivalent electrolytes, the results of LaMer and his co-workers for the solubilities of luteocobaltic dianminotetranitrocobaltiate (LN_3), luteocobaltic diamminodinitroöxalatocobaltiate (LO_3), and $La_2(IO_3)_3$ in very dil. K_2SO_4 solns. being used. It is shown that the deviations from the Debye-Huckel theory of dil. solns. ("the elec. type effect" or "the unsymmetric valence type effect") are due wholly to the incomplete dissocn. of the salts concerned. In the calcns. it is assumed that at these high dilns. only the 2 ions of high valency are assocd. (in these cases the L^{+++} or La^{+++} and the SO_4^{--} ions), the salt being otherwise completely dissocd. Thus, the deviation of the actual soly. from the theoretical (as detd. by the Debye-Huckel limiting equation) is due in these solns. to either the LSO_4^+ or $LaSO_4^+$ ions, whose concns. in the solns. are calcd. The value of the dissocn. const. obtained for the $LaSO_4$ cation agrees closely with that derived from the cond. of $La_2(SO_4)_3$ solns. J. BALOZIAN

Thermodynamic properties of weak acids and bases in salt solutions, and an exact method of determining their dissociation constants. HERBERT S. HARNED AND BENTON B. OWEN. *J. Am. Chem. Soc.* 52, 5079–91(1930).—The method of calcg. dissocn. consts. from e. m. f. of cells without liquid junction developed in an earlier paper by Harned and Robinson (*C. A.* 23, 752) is extended in a study of HCOOH in *M* solns. of KCl and NaCl. The equation $\log k' - \sqrt{\mu'} = \log k^0 - 2B\mu'$ is shown to be valid in dil. solns. by plotting $\log k' - \sqrt{\mu'}$ against μ' for HOAc′ and HCOOH and obtaining a straight line. The values of the dissocn. const., K, calcd. without extrathermodynamic postulates are: for the acids, HOAc (1.75×10^{-5}), and HCOOH (1.77×10^{-4}), and for the bases derived from NH_3 (1.79×10^{-5}), CH_3NH_2 (43.8×10^{-5}), $(CH_3)_2NH$ (52.0×10^{-5}) and $(CH_3)_3N$ (5.45×10^{-5}). Full details of the method of calcn. are given. A. LLOYD TAYLOR

The temperature coefficient of dissociation of acetic acid in potassium and sodium chloride solutions. HERBERT S. HARNED AND GEO. M. MURPHY. *J. Am. Chem. Soc.* 53, 8–17(1931).—E. m. f. measurements at 20°, 25° and 30° were made of the cells H_2 | HCl (0.01 *M*), MCl (*m*) | AgCl | Ag and H_2 | AcOH (0.2 *M*), MCl (*m*) | AgCl | Ag where MCl = KCl and NaCl and *m* varied from 0 to 3.0 *M*. Temp. coeffs. of the cells were calcd. from a linear formula. From the results, the activity coeffs. and relative partial heat content of HCl in the salt solns. were calcd. The H-ion concn. and ionic

activity coeffs. were calcd. for AcOH in the salt solns. The dissocn. const. of AcOH varies very little from 20° to 30° and is found to be 1.75×10^{-5}. The excess or elec. contribution to the partial molal heat content of HCl in the salts solns. is found to be approx. proportional to the square root of the total molality. G. M. MURPHY

Activity coefficients of electrolytes. V. The principle of specific interaction in cadmium and magnesium sulfate and chloride solvents. HAROLD B. FRIEDMAN AND VICTOR K. LAMER. *J. Am. Chem. Soc.* **53**, 103-5(1931); cf. *C. A.* **23**, 5085.—Soly. measurements at 25° were made of $TlIO_3$ and $La(IO_3)_3$ in 0.05 *M* soln. of $MgSO_4$, $CdSO_4$, $MgCl_2$ and $CdCl_2$. The ratio Mg/Cd in soln. of the 2 satg. salts is almost identical when the anion present is SO_4. The $(SO_4/Cl)Mg$ ratio is lower than previously reported but may be due to analytical error. The results for $CdCl_2$ indicate that the specific interaction principle does not hold for this salt G. M. MURPHY

A summary of oxidation-reduction potentials. (a) Ferric-ferrous electrode; (b) mercuric-mercurous electrode; (c) manganese dioxide electrodes. STEPHEN POPOFF, A. H. KUNZ, J. A. RIDDICK AND W. W. BECKER. *Proc. Iowa Acad. Sci.* **36**, 263-4 (1929).—(*a*) The standard oxidation-reduction potential of the ferric-ferrous electrode was detd. from e. m. f. measurements of the cell: Pt, H_2 | HCl | HCl + $FeCl_3$ + $FeCl_2$, Pt. The concn. of the HCl was kept the same in both half cells in each series but the concn. of the ferric and ferrous salts was varied, the ratio being maintained equal to one. The acid concn. in the series consisted of 0.05, 0.1, 0.2, 0.5 and 1 molal HCl. From inspection of the equation $E = E_0 - 0.05915 \log \frac{C_{Fe^{\cdots}}}{C_{Fe^{\cdot\cdot}}} - 0.05915 \log \frac{\cdots}{Fe} \pm E_1$ it can be seen that the terms to the right of E_0 must be made equal to zero in order that E may equal E_0. By suitable math exptl. and graphical treatments, the foregoing were reduced to zero, and thus 2 of the former difficulties in interpreting oxidation-reduction potentials were eliminated. These difficulties are the uncertainty in regard to liquid-junction potentials and activity of one ion in the presence of other ions (see *C. A.* **23**, 1802). (*b*) E. m. f. measurements of the cell Pt, H_2 | $HClO_4$ | $HClO_4$ + $Hg(ClO_4)_2$ + $Hg_2(ClO_4)_2$, Pt were made. The mode of attack was similar to that in (*a*). (*c*) Attempts to measure the potentials of the $MnO_4^- - H^+ - MnO_2$ electrode and that of the MnO_2, H^+, Mn^{++} electrode failed because of secondary reactions of the electrode and because of the irreversibility of these electrodes (see *C. A.* **24**, 4465). W. G. GAESSLER

The theory of surface polarization. W. J. MÜLLER. *Z. Elektrochem.* **36**, 679-86 (1930). The present conflicting theories are reconciled by assuming that each of the 3 principal theories previously proposed (the oxide-film theory, the O theory and the metal theory) participate. A. P. SACHS

The determination of oxidation-reduction potentials from equilibrium data. STEPHEN POPOFF, V. B. FLEHARTY AND E. L. HANSON. *Proc. Iowa Acad. Sci.* **36**, 265(1929).—The detn. of the oxidation-reduction potentials is more reliable from equil. data than from e. m. f. data. The potential of the ferric-ferrous electrode was calcd. from the experimentally detd. equil. const. of the reaction: $2Fe(ClO_4)_3 + 2Hg \rightleftharpoons 2Fe(ClO_4)_2 + Hg_2(ClO_4)_2$. The perchlorates, Hg and $HClO_4$ are better suited for the detn. of the equil. const. than the nitrates, Ag and HNO_3 employed by Noyes and Brann (*C. A.* **6**, 3350). The true equil. const. of the reaction was detd. by suitable exptl. procedure and subsequent math. and graphical analysis. W. G. GAESSLER

Theory of passivity. XII. The passage of current through anodes, covered with an insoluble layer. WOLF J. MÜLLER. *Monatsh.* **56**, 191-6(1930); cf. *C. A.* **24**, 4786. With the aid of the law of Kirchhoff the relation between the current in the coating layer and that in the pores of a coated anode is expressed in a formula. With a poorly conducting layer the current in the pores is the total current and with increasing cond. the current goes more to the layer. The localized current metal-electrolyte in the pores of the layer is practically zero before the decompn. potential of the anode has been reached and reaches only values of a few ma. The theoretical potential of the formation of ferrate by the electrolysis of Fe in hot concd. alkalies is —0.15 v.; however, the observed potential is 0.65. The p. d. in the pores must be 0.84 v. E. SCHOTTE

Potential measurements of hydrogen electrodes in acid solutions in ether. GEROLD SCHWARZENBACH. *Helv. Chim. Acta* **13**, 896-907(1930).—The app. and materials used and the method of investigation are described in detail and the results tabulated for various concns. of H_2SO_4 for CCl_3CO_2H, HCl + alc., H_2SO_4 + alc., AcOH, and AcOH + varying amts. of H_2SO_4. In spite of uncertainties in the measurements it

is concluded that the acidity of acids in Et_2O soln. is much greater than in H_2O; over 10,000 times for a 2 *N* soln. of H_2SO_4, the acidity being almost independent of the concn. The Et_2O soln. of CCl_3CO_2H shows a strong acidity increase with concn., a 2 *N* soln. being as acid as H_2SO_4 and notably more so than HCl. Alc. and AcOH lower the acidity of H_2SO_4 as the H_2SO_4 concn. decreases and the quantities added increase. J. H. MOORE

Low-temperature oxidation. III. The lag in ignition of some hydrocarbons. JOHN S. LEWIS. *J. Chem. Soc.* 1930, 2241–54; cf. *C. A.* 24, 2715.—A comparative and qual. study was made of the effect of catalysts on the lag in ignition of hydrocarbons, by a modification of the "crucible" or drop method of Moore (*C. A.* 11, 1745). Catalysts that promote oxidation of hydrocarbons raise their ignition point and lower the temp. at which ignition ceases, when present in fairly large quantity. At higher temps. and in the presence of a min. amt. of catalyst, the time of lag is diminished. Those catalysts that do not promote this oxidation or have slow action (Zn and Sn in polished strips) affect the ignition temp. and lag but little. By the drop method, the promoters and inhibitors of knocking can increase the ignition temp. and the lag of paraffins. In general, the activities of pro- and anti-knock reagents cannot be compared by their effects on the ignition temp. and the lag. In the theory of Charch, Mack and Boord (*C. A.* 20, 1510), the idea of flameless combustion is substituted for active combustion ahead of the flame front induced by Pb particles and Et radicals. J. BALOZIAN

The influence of p_H values on the oxidation of ferrous sulfate. JACOB CORNOG AND ALBERT HERSHBERGER. *Proc. Iowa Acad. Sci.* 36, 264–5(1929).—Weighed quantities of $FeSO_4$ were dissolved in buffered solns. after which the resulting buffered solns. of $FeSO_4$ were aerated for 3 hrs. The quantity of Fe remaining unoxidized after 3 hrs.' aeration was, in each case, detd. by titrating the aerated soln. with $KMnO_4$ soln. The degree of oxidation was found to vary both with the initial concn. of $FeSO_4$ and with the p_H of the soln. These data indicate that under the exptl. conditions used little or no Fe is oxidized in soln. having a p_H less than 5. In solns. buffered to a p_H 5 the degree of oxidation increases with increasing Fe concn., but in solns. buffered to a p_H = 10 the degree of oxidation decreases with increasing Fe concn. The influence of the length of time of aeration on the degree of oxidation of a 0.01 *M* $FeSO_4$ soln. buffered to p_H 5 was studied. Different portions of the same 0.01 *M* $FeSO_4$ that had been buffered to p_H 5 were aerated for different periods of time. After aeration each portion was titrated with $KMnO_4$ soln. to det. the portion of Fe still unoxidized. The relation between the duration of oxidation and the percentage of Fe oxidized is expressed by the following equation: $\ln T = 0.032x - 0.01$. In this equation x is the percentage of Fe oxidized by aeration in T hrs. W. G. GAESSLER

A simple electrochemical method for the simultaneous determination of the constitution and equilibrium constant of complex ions in solution. Application to complex silver ions. FREDERICK K. V. KOCH. *J. Chem. Soc.* 1930, 2053–63.—A method is described for simultaneously detg. the constitution and equil. const. (when small) of complex ions in soln. from e. m. f. (E) measurements, showing its application to the Ag ion in NH_3-H_2O, acetonitrile-H_2O, pyridine-H_2O, and pyridine-EtOH mixts. In the first 3 cases E is det. exptly. for the cell $Ag \left| \begin{matrix} AgNO_3 \text{ in} \\ H_2O\ (c) \end{matrix} \right| \left| \begin{matrix} AgNO_3 \text{ in} \\ \text{mixt. } (c) \end{matrix} \right| Ag$, where c = 0.1 *M*, 0.01 *M*, or 0.001 *M*. Substituting this value for E in: $E = (RT/nF).\log_e[\gamma_{AB} \div (K_m/m^x)]$, ($K_m$ = equil. const. for concns. in g.-mols./l., γ_{AB} = the ratio of the soln. tensions in the solvents A and B, and has been previously detd. (*C. A.* 22, 1893), and x = no. of mols. of A with which a Ag ion is solvated), $\log_{10} K_m/m^x$ can be detd. This equation is a special case obtained from the general formula (deduced in the text) by assuming the liquid-liquid potential to be negligible. To det. $\log_{10} K_m/m^x$ when a pyridine-EtOH mixt. is used cond. detns. are made (*loc. cit.*) and used in conjunction with: $(RT/nF).\log_e[\gamma_{AB} + (K_m/m^x)] = (RT/nF).\log_e \gamma_{sat} - 0.126$. By plotting $\log_{10} K_m/m^x$ against $\log_{10} m$, K_m and x can be detd. simultaneously. Such a graph shows the points to lie about a straight line with slope $x = 2$ in accordance with $Ag_2A_2^{++}$. The acetonitrile-H_2O mixts. gave points which did not lie on a straight line, showing that the conditions for the detn. of the equil. const. were not fulfilled. J. B.

Molecular attractive forces and the velocity of chemical reactions. C. C. COFFIN AND O. MAASS. *Can. J. Research* 3, 526–39(1930); cf. *C. A.* 22, 2139, 2140.—The reactions between HCl and α, β and γ-butylene were investigated in both the liquid and the gaseous states. The effect of temp., 0–25°, and the concn. of the reactants on the reaction velocities was studied and the reaction products were examd. In the liquid state the γ-isomer reacts rapidly, the α- much more slowly and the β- most slowly of

the three. In the gaseous state at atm. pressure only γ-butylene shows a measurable reaction which is bimol. and probably heterogeneous. Where possible, the f.-p. curves of the systems were detd. in order to ascertain the extent of mol.-compd. formation. No phys. evidence of high concn. mixts. of HCl and olefin as solns. of mol. compd. in HCl was obtained. In spite of the absence of any abrupt change in phys. properties the results are believed to indicate a relationship between mol. attraction and reaction velocity. A catalytic factor peculiar to the liquid state is suggested. J. W. S.

Effect of intensive drying on the velocity of gaseous reactions. C. C. COFFIN AND O. MAASS. *Can. J. Research* 3, 540–2(1930); cf. preceding abstr.—An attempt to study the reaction HCl + NH_3 when both had been subjected to intensive drying was frustrated by the failure to obtain HCl sufficiently free from moisture as a result of the formation of oxychloride and H_2O in the reaction of HCl with P_2O_5. Redistd. P_2O_5 from an elec. furnace contg. spongy Pt and in an atm. of O_2 was used as the drying agent for CO_2, the CO_2 being kept in contact with the P_2O_5 for 3 months. NH_3 was dried in contact with CaO followed by contact with BaO for 3 months. When the dried gases were mixed no reaction took place. The mixt. of gases was condensed by liquid air and then permitted to warm up. Most of the CO_2 vaporized before the NH_3 melted but the residual CO_2 immediately reacted with the liquid NH_3 to form solid ammonium carbamate. It is concluded that the reaction in the liquid condition indicates a catalytic effect of the liquid phase. J. W. SHIPLEY

Kinetics of the reaction between persulfate and thiosulfate ions in dilute aqueous solution. CECIL V. KING AND OTTO F. STEINBACH. *J. Am. Chem. Soc.* 52, 4779–95 (1931).—The velocity of the uncatalyzed reaction $S_2O_8^{--} + 2S_2O_3^{--} \longrightarrow 2SO_4^{--} + S_4O_6^{--}$ is approx. pseudo-unimol. and is independent largely of $[S_2O_3^{--}]$; but the salt effect shows that the rate-detg. reaction is between 2 neg. ions. From the reaction catalyzed by I^- the const. for the bimol. reaction $S_2O_8^{--} + 2I^-$ is calcd. and is 20% lower than when the rate is measured independently. The const. for the $S_2O_8^{--} + Cu^{++}$ reaction is calcd from the reaction catalyzed by Cu^{++}. The $S_2O_8 + Cu^{++}$ reaction is between two neg. ions as shown by the salt effect and since Cu^{++} is reduced to $Cu(S_2O_3)_y^{-x}$ by $S_2O_3^{--}$. Sugar increases the velocity of the $S_2O_8^{--} + S_2O_3^{--}$ reaction and of the $S_2O_8^{--} + 2I^-$ reaction in the presence of $S_2O_3^{--}$. S. LENHER

The influence of solvent on the decomposition of trichloroacetic acid. J. N. PEARCE AND A. C. NELSON. *Proc. Iowa Acad. Sci.* 36, 251–60(1929).—The velocity of decompn of CCl_3CO_2H to $CHCl_3$ and CO_2 was detd. for its solns. in water, aniline and in binary solvent mixts. of aniline and $CHCl_3$, and of aniline and toluene. In all of these the decompn. follows the general unimol. reaction law. In EtOH and MeOH and in $CHCl_3$, toluene and pyridine there is no measurable decompn. The reaction is found to proceed more rapidly in the light than in the dark, regardless of the nature of the solvent. The temp. coeffs of the reaction in the light are greater than those in the dark for all of the solvents studied, except in pure aniline and in the aniline-$CHCl_3$ mixt. contg. 87.5 mol.-percent of aniline. Only in the last 2 solvents is the photocatalytic influence of the light believed possible. In all of the other solvents studied the light seems to act only by increasing the absorbable radiation density of the system. The heats of activation per mol. of acid are calcd. for each solvent. The velocity consts. calcd. from the heats of activation by the equations of Dushman and of Lewis do not agree even approx. with the experimentally detd. values. W. G. G.

Kinetics of acetylene-oxygen reaction. ROBERT SPENCE AND GEORGE B. KISTIAKOWSKY. *J. Am. Chem. Soc.* 52, 4837–47(1930); cf. *C. A.* 25, 20.—The reaction rate is accelerated by O_2 when C_2H_2 is in excess, but is retarded by it when in excess. At the optimum O_2 concn. the rate is proportional to $[C_2H_2]^2$; with less O_2 it is proportional to a lower power of $[C_2H_2]$. N_2 retards the rate slightly. In the presence of reacting C_2H_2, HCHO is oxidized much faster than when alone. S. LENHER

Physical measurements of short-lived intermediate products. H. SCHMID. *Z. Elektrochem.* 36, 769–71(1930).—See *C. A.* 24, 4690. A. P. SACHS

Graphic demonstration of a theorem of Roozeboom. A. MAZZUCCHELLI. *Gazz. chim. ital.* 60, 719–21(1930).—In dealing with the 3 curves of univariant equil. which, in [illegible] nt system, depart from each invariance point, Roozeboom (cf. *Heterogene Gl.* 1, 98), demonstrated a theorem according to which at const. pressure m pr[illegible] to the invariant point the transformation curve of max. heat absorption which [illegible] middle position. Related to this is a theorem of Duhem, according to of max. const. temp. in proximity to the invariant point the transformation curve diminution of vol. occupies the middle position. These 2 theorems were [illegible] curves. In the present paper it is shown that the same result is obtained by

a graphic method based on the simple application of the Le Chatelier law.
C. C. DAVIS

Graphical treatment of the thermodynamics of the rectifying column. W. H. KEESOM. *Proc. Acad. Sci. Amsterdam* **33**, 901–8(1930). E. H.

Thermodynamic study of the phasial equilibria in the system: iron–carbon. CHU-PHAY YAP. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. **381**, 26 pp.(1931).—Previously published Fe-C diagrams are reviewed and the disagreements regarding the shapes of the liquidus and solidus are pointed out. Y. then replotted the Fe-C diagrams and calcd. C as mol. % and as mol. % Fe-C. Thermodynamic laws of solns. that apply to a diagram of this type were calcd. and values taken from the various Fe-C diagrams were substituted to det. which was the more nearly correct. The results indicated that in the liquid state C exists mainly as Fe_3C, but in the solid γ Fe it is dissolved as C. The correct liquidus bounding the field Δ + melt is probably that of Ruer and Goerens (*C. A.* **12**, 2524) which is slightly convex. In the delta field C is dissolved as such in the melt. Heat of fusion of γ Fe is calcd. as 66.4 cal. per g. Heat of fusion of γ Fe is calcd. as 66.4 cal. per g. Heat of transition of γ to Δ Fe is about 2.0 cal. per g. and accordingly the heat of fusion of Fe is about 64.4 cal. per g.
A. W. HOLMES

Influence of dissolved carbide on the equilibria of the system: iron–carbon. CHU PHAY YAP. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. **382**, 19 pp.(1931).—Previously published data on the Fe-C diagram are used to discuss the shape of the solidus. The straight solidus is obtained by cooling a sample from the melt, while the curved solidus is obtained by heating samples that have already reached room temp. Fe_3C exists as a structurally stable phase that the austenite must redissolve. This leads to the conclusion that within a certain range of temp. the C in soln. in austenite must be in the form of a carbide. A. W. HOLMES

The catalytic action of hydrogen on the carbon monoxide flame. W. E. GARNER AND D. A. HALL. *J. Chem. Soc.* 1930, 2037–47.—The effect of H_2 on the CO flame is investigated, the "dry" mixt. and others contg. 0.019, 0.0315, 0.0537, 0.101, 0.200, 0.517 and 2.02% H being used. The app. is essentially that of Garner and Roffey (*C. A.* **23**, 4406), quartz windows being employed instead of the fluorite to minimize radiation losses due to absorption of the gases ahead of the flame. Radiation by log speed and radiation-pressure curves show a "step" at 0.03% H_2 for gases initially at 1 atm. At the "step" the H_2 pressure is greater the lower the combined CO and O_2 pressures; thus $p_{H_2}p_{gas}$ = const. The radiation-pressure curves for H_2-O_2 flames are concave to the radiation axis and pass through the origin; for the "dry" CO flame it is linear and intercepts the pressure axis at p = 12 cm.; and, for H_2-CO flame, the curves are concave to the pressure axis. The radiation-pressure curve for the "dry" CO flame is concluded to be mainly chemiluminescent. An irregularity appears in the curves above the "step," this irregularity moving lower with increasing H_2 concn. The extinction coeffs. of gases in front of the flame were calcd. from radiation readings through quartz and through fluorite windows. Below 0.03% H_2 the decrease in radiation is given by: $R = R_0k_1/(k_1 + k_2[H_2O])$, ($R_0$ = radiation of H_2-free gas). The fall in radiation at the step is proportional to that above the step. J. BALOZIAN

Acid and salt effects in catalyzed reactions. XXIV. A study of the catalytic effects produced by acetic acid and acetate buffers under conditions of effectively constant ionic environment. HARRY M. DAWSON AND ERIC SPIVEY. *J. Chem. Soc.* 1930, 2180–9, cf. *C. A.* **24**, 2945.—A study was made of the catalytic effects assocd. with the acetone-I reaction in the presence of (*a*) const. AcOH + variable AcONa buffers, (*b*) AcOH, (*c*) AcOH + HCl and (*d*) isohydric buffers, in 0.75 *N* NaCl soln. (to insure an approx. const. ionic environment). Since the catalytic effects of H_2O, and the H and OH ions are very small in acetate buffers, the existence of a further catalytic agent, a complex acetate ion ($CH_3.CO_2H$, $CH_3.CO_2)^-$, is postulated. There is close agreement between the observed and the calcd. values of the reaction velocity (v), the equation used in calcg. being: $v = k_h[H^+] + k_a[A^-] + k_a'[HA_2^-] + k_m[HA] + k_{OH}[OH^-] + k_w[H_2O]$, where k_h = 561 × 10^{-6} (for the H ion), k_a = 3.35 × 10^{-6} (for the acetate ion), k_m = 1.30 × 10^{-6} (for undissocd. AcOH), $k_a'K'$ = 3.5 × 10^{-6} (for the complex ion), k_{OH} = 7 (for the OH ion) and $k_w[H_2O]$ = 0.006 × 10^{-6} (for undissocd. H_2O), all being referred to an acetone concn. of 20 cc./l. at 25°. Under the conditions of these investigations the relations are the same as in earlier ones in which the reactants were dissolved in H_2O. J. BALOZIAN

Autocatalysis in oxidation. II. Action of catalysts on the autoxidation of abietic acid. G. DUPONT AND J. LÉVY. *Bull. inst. pin* 1930, 248–52.—See *C. A.* **24**, 2945.

Reactions at the surface of hot metallic filaments. IV. The reaction of $CO_2 + H_2 \longrightarrow H_2O + CO$ on tungsten and thoriated tungsten. B. S. SRIKANTAN. *J. Indian Chem. Soc.* **7**, 745–57(1930); cf. *C. A.* **24**, 2036.—After W wire had been used a short while, it attained a steady state of activity for the interaction of CO_2 and H_2. The temp. coeff. and energy of activation decreased with rising temps. and the reaction velocity increased with the pressure of H_2. Since the surface became satd. with CO_2 below 200-mm. pressure, further increases in the pressure of CO_2 did not change the reaction velocity. Thoriated wire was not found to give a const. state of activity.
L. P. HALL

Comments on the paper by Fenton and Garner entitled "The heats of association of acetic and heptoic acids in the vapor state." HANS DOHSE AND MANFRED DUNKEL *J. Chem. Soc.* 1930, 2409–10; cf. *C. A.* **24**, 3703.—To compare the heat of dissocn. of the double AcOH mol with the heat of vaporization, the latter should be detd. from the change of vapor tension with temp. rather then calorimetrically (as F. and G. detd. it). The value given by them for AcOH should be cut in two (6900 cal.). The heat of assocn. of 2 g.-mols. of benzoic acid is calcd. by the van't Hoff isochore as 1.12×10^4 cals. (5700 cals./mol.). Exception is taken to F. and G.'s conclusion that the assocn. of acetic is concerned with a "chem." combination, since the forces between the mol. are apparently caused by the mutual electrostatic influence of 2 dipoles. J. B

Heat of combustion of camphor, azobenzene and hydrazobenzene. W. SWIETOSŁAWSKI AND J. BOBIŃSKA. *Bull. intern. acad. Polonaise* **1929A**, 621–30(in French) — see *C. A.* **24**, 1790.

Heats of adsorption and isotherms in the system platinum-hydrogen. EDWARD B. MAXTED. *J. Chem. Soc.* 1930, 2093–2100.—The curves of the *heat of adsorption* (I) of H_2 by Pt are detd., and the effect of "aging" of the catalyst (Pt-black) on I and on the H_2 isotherm is investigated. The app. used is essentially similar to that of McKie (*C. A.* **23**, 1550), the Pt-black being prepd. by the method of Mond, Ramsay and Shields (*J. Trans.* **186A**, 657(1895)) and at no time during the expts. exposed to temps. above 100°. The curves of the differential I per mol. H_2 against the H_2 adsorbed fail to show a pronounced max. which becomes flattened (by elimination of the peak) on "aging." The total heat evolved during the adsorption of a given amt. of H_2 is found to decrease with the age of the Pt catalyst. The isotherms, obtained by plotting pressure (mm.) against H_2 adsorption (cc.), show an initial stage in which most of the H_2 is adsorbed almost instantaneously at low pressures (94% in 3 min., 96% in 7 min.). After this a relatively large increase in pressure does not greatly influence the adsorbed H_2 content. The isotherms shift gradually toward the pressure axis with time. It is suggested that both I and the H_2 isotherms are specific for the particular condition and history of the hydrogenation catalyst. In the adsorption of H_2 on various metals, the heat effect is due, principally, to a common process, specific for the H and independent of the metal.
J. BALOZIAN

The heats of adsorption of organic vapors on charcoal at 25° and 50°. G. H. REED AND J. N. PEARCE. *Proc. Iowa Acad. Sci.* **36**, 262(1929).—The method of Pearce and McKinley (*C. A.* **22**, 1524) was used to det. the heats of adsorption of certain org. vapors on charcoal at 25° and 50°. The vapors used, CCl_4, $CHCl_3$ and CH_2Cl_2, were chosen with the purpose of ascertaining the possible effect both of the mol. configuration and the no. and nature of the substituents upon the heat of adsorption. The results indicate only 2 conclusions: (1) If there is a temp. coeff. of heat of adsorption it is very small, and (2) the successive addn. of Cl atoms to a mol. does not produce a regular variation in the mol. heat of adsorption. The heat of adsorption increases as the no. of Cl atoms in the mol. is increased.

SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

W. ALBERT NOYES, JR.

The proper energy of the electron. WERNER HEISENBERG. *Z. Physik* **65,** 4–13 (1930).—Math. E. BRETSCHER

The distribution of electrons in the atom. L. GOLDSTEIN. *Compt. rend.* **191,** 766–8(1930).—Dirac's method is extended to obtain a differential equation for the at. potential. Using the Fermi statistics the at. potential can be represented as having 2 terms, the 2nd term being a resonance effect. S. BRADFORD STONE

Characteristics of nuclear electrons. J. KUDAR. *Physik. Z.* **32**, 34–7(1931).—Theoretical. A discussion of continuous beta-ray emission on the basis of modern quantum theory. WILLIAM E. VAUGHAN

A possible conception of nuclear phenomena. MAURICE DE BROGLIE. *Compt. rend.* **191**, 689–90(1930).—Disintegration is not a purely internal process. In the nucleus the mean mass of the proton is a little less than that of the free proton (packing effect). At the moment of formation of the nucelus there is a loss of internal energy. The nuclear stability depends on grouping. The stability of the atoms varies; the packing coeff. varies; the abs. internal energy of the nucleus should not remain const. An absorption and emission of protons by the nucleus can hardly be imagined, but a sort of equil. of radiation is implied. It becomes necessary to consider the nuclei surrounded by an external radiation. This idea is distinct from that of Jean Perrin to explain radioactivity by a kind of photo effect of radiation. L. D. ROBERTS

The structure of ultra-radiation. I. W. S. PFORTE. *Z. Physik* **65**, 92–101 (1930).—Previous expts. with 2 ionization chambers by G. Hoffmann and W. S. Pforte (*Physik. Z.* **31**, 347(1930)) revealed fluctuations of intensity of the ultra-γ-radiation. Expts. were now carried out to show that this effect was not due to exptl. error. A completely automatic compensation for the ionization chambers was set up in a salt mine, the residual ionization detd. and the influence of Ra-γ-radiation on the fluctuations of the current studied. *Result.*—The fluctuations observed by H. and P. are real and not due to exptl. error. EGON BRETSCHER

Supplementary note to my paper: The probability law for the decomposition of radioactive materials in very small concentration. G. I. POKROVSKII. *Z. Physik* 65, 133–8(1930); cf. *C. A.* **24**, 1279.—According to the law of radioactive decay the no. of radioactive atoms ought to be a function of time *t*: $\lg N = \lg N_0 - mt \lg e$, N_0 being const. This process was studied by counting the no. of scintillations on a ZnS screen contg. a radioactive substance in very low concn. ($c \sim 10^{-12}$ g. Ra equiv./sq. mm.) It is found that N_0 is not a const. and that the deviation from the const. becomes larger the smaller the concn. of the radioactive prepn. EGON BRETSCHER

Artificial excitation of the nuclear γ-radiation. W. BOTHE AND H. BECKER. *Z. Physik* **66**, 289–306(1930); cf. *C. A.* **24**, 5220.—Thin plates of materials are bombarded with Po α-radiation and the γ-radiation resulting therefrom is traced with a Geiger counter. The following elements and compds. are investigated: Li_2CO_3, Li, Be, B, C (graphite), paracyanogen, Ca, CaF_2, sugar, Ne, fused Na_2CO_3, Al, Mg and Ag. Of these only Be, Li, F, Al, Mg or compds. contg. these elements give rise to a secondary radiation (Be is the strongest and the following elements are radiators of diminishing intensity). From the absorption in Pb, it is concluded that the wave length of this radiation must be of the same order of magnitude as that from Ra. The intensity of the radiation from Be as function of the energy of the α-particles possesses probably a max. value for a certain velocity of the α-particles, pointing thus to a quantum mech. resonance effect. The hardness of the γ-radiation does not perceptibly change with the range of the exciting α-particles. A discussion of the possible course of the excitation mechanism is given which is based on Gamov's potential model and on the exptl. data on the disintegration expts. (H-rays of Pose, *C. A.* **24**, 5219.) EGON BRETSCHER

A γ-radiation from polonium. W. BOTHE AND H. BECKER. *Z. Physik* **66**, 307–10; *Naturwissenschaften* **18**, 894–5(1930).—Previous expt. (cf. preceding abstr.) revealed the existence of a weak γ-radiation from Po. This is further confirmed and it is assumed that these rays are of secondary nature and due to self-excitation of the decaying Po nucleus. EGON BRETSCHER

The removal of radon from an emanation chamber after use. C. L. UTTERBACK AND D. DEVAPUTRA. *Rev. Sci. Instruments* **2**, 53–4(1931).—The description of a simple app. is given in which the chamber can be cleaned out in about 0.5 hr. after use with natural H_2O contg. 10^{-10} g. Ra per l., and in 1.5–3.0 hrs. with H_2O contg. 4×10^{-6} g. J. H. MOORE

The radioactivity of Stone Mountain springs. JAMES A. HOOTMAN AND V. NELMS. *Am. J. Sci.* [5], **21**, 37–8(1931).—Electroscopic measurement of the Ra emanation from 14 samples of water from springs around Stone Mt. showed 0.40 to 1 av. 4.2, millimicrocuries per l. ALDEN H. EMERY

Experiments with high-velocity positive ions. J. D. COCKCROFT AND E. T. S. WALTON. *Proc. Roy. Soc.* (London) **A129**, 477–89(1930).—Detailed description of a 300-kv. thermionic rectifier, used in connection with a tube for the production of accelerated canal ray protons. FRANK URBAN

A new method for recording electrons. PERCY H. CARR. *Rev. Sci. Instruments* **1**,

711–43(1930).—Some of Cole's work (*C. A.* **20**, 3638; **21**, 207) was repeated with the original app. and with a new glass camera which is described in detail. Metal surfaces are affected by electron bombardment (*C. A.* **24**, 4455) even at the low speed of 12 v., and expts. with Au and Ag are given in detail, while expts. were made on brass, Pt, Ni and Cu, with good results except with Cu. The expts. indicate that the effect is not due to elec. charging or polarizing of the gas film on the metal surface, but may be due to freeing the surface of the gas film. Other possible causes are discussed. Other advantages of metals over dry plates are: they do not build up potentials which alter the paths of the electrons. Relatively high c. d. permits shorter exposures, and metals are unaffected by light. J. H. MOORE

Polarization of electrons. G. P. THOMSON. *Nature* **126**, 842(1930).—The detection of polarization by successive reflection from thin gold films is possible only with large angles of scattering. ARTHUR FLEISCHER

Application of the diffraction of electrons to the study of organic substances—structure of cellulose. A. DAUVILLIER. *Compt. rend.* **191**, 708–11(1930); cf. *C. A.* 24, 4212.—To obtain clear interference figures from electrons, the object under investigation must be very thin (100 A. U.) to prevent excessive absorption of electrons and static charges. Films of nitrocellulose, cellulose acetate and celluloid were made by evapg. solns. on Hg surfaces and on water. The diffraction patterns at 11–21 kv. are entirely different from those obtained by x-rays as they consist of 3 concentric halos. In the case of one film coated on a water surface, evidence was obtained that the micelles were orientated normal to the plane of the films. J. G. MCNALLY

The effective cross section of krypton for slow electrons. J. HOLTSMARK. *Z. Physik* **66**, 49–58(1930).—The effective cross section of Kr is calcd. using D. R. Hartree's at. field. The mutual polarization energy (which for large values of r is proportional to r^{-4}) has to be taken into account. Agreement with the curves of Ramsauer and Kollath is obtained and the cross section for rectangular deflection agrees with the exptl values up to 15 v. EGON BRETSCHER

New measurements of the effective cross section of gases and vapors. F. SCHMIEDER. *Z. Elektrochem.* **36**, 700–4(1930).—The relationship between HCN, C_2H_2, N_2, $(CH_3)_2O$, $(CH_3)_2NH$, etc., according to Grimm's law is confirmed by position and shape of effective cross section-electron velocity curves. Isomers give various curves, e. g., almost identical (*n*-pentane and $C(CH_3)_4$; butane and isobutane) to totally different (CH_3OH and C_2H_5OH), the difference in the latter case being probably due to dipole moments. A. P. SACHS

Remarks on the paper by Bröse and Saayman: Cross-section measurements of molecules other than inert gases with slow electrons. E. BRÜCHE. *Ann. Physik* [5], 7, 577–87(1930). **Answer.** H. L. BRÖSE AND E. H. SAAYMAN. *Ibid* 588–95. **Rebuttal.** E. BRÜCHE. *Ibid* 596–600.—Cf. *C. A.* **24**, 5218. L. ONSAGER

Discharges in neon. P. JOHNSON. *Phil. Mag.* **10**, 921–31(1930); cf. Townsend and Nethercot, *C. A.* **23**, 5408.—As found in the case of N_2, the mean elec. force in the luminous column of a high-frequency discharge in Ne is independent of the current from 1 to 10 ma. and of the wave length of the oscillator from 30 to 120 m. A. F.

Investigation of high-frequency discharges. II. Methane, methyl chloride, dichloromethane, chloroform, carbon tetrachloride. P. N. GHOSH AND B. D. CHATTERJI. *Z. Physik* **65**, 102–6(1930).—The study of the visual aspect of high-frequency discharges passing through org. vapors is continued (*C. A.* **24**, 778). If the pressure, at which a certain no. of striations appear is plotted against the mol wt., a curve is obtained which approaches asymptotically the mol.-wt. axis. EGON BRETSCHER

High-frequency electrodeless discharge characteristics. OTTO STUHLMAN, JR. AND M. D. WHITAKER. *Rev. Sci. Instruments* **1**, 772–9(1930).—The expts. were made with a spherical Pyrex bulb contg. Hg vapor at 25° and air at pressures of 3–60 microns, placed in a helical coil carrying damped high-frequency currents with range of 1800–555 kilocycles and current of 0.8–1.6 amps. The visual intensity was measured with a L. & N. flicker photometer. No simple relation was found between visual intensity and air pressure, current or frequency, but there were consistent irregularities. Const. current and pressure max. values of visual intensity were found for wave lengths of 252, 358 and 490 m., corresponding to frequencies of n, $n + k$, and $n + 2k$. References are given. J. H. MOORE

An investigation of the critical potentials of the spark spectrum of cadmium. DEVER COLSON. *Proc. Iowa Acad. Sci.* **36**, 307(1929).—The direct spectroscopic method was used in which the spectrum was excited by electron impact. The accelerating voltage on the electrons was varied from 8.8 (ionization potential of Cd) up to 200 v.

Measurements on the films were made with a microphotometer. The effects of change of plate current and vapor pressure were investigated. W. G. GAESSLER

Collisions of the second kind between electrons and excited mercury atoms. G. D. LATUISHEV AND A. I. LEIPUNSKII. *Z. Physik* **65**, 111–23(1930).—See *C. A.* **24**, 4703. EGON BRETSCHER

The temperature dependence of the interfacial photoelectric effect observed on copper-copper oxide cells. HORST TEICHMANN. *Z. Physik* **65**, 709–13(1930).—This photoelec. effect is observed on the boundary of unipolar half conductors with metals on irradiation with light. The photoelec. current is 25 times larger when the temp. is lowered from room temp. to —80°. Potential, current and resistance are stated as function of temp. EGON BRETSCHER

The origin of photoelectrons in copper-cuprous oxide photoelectric cells. W. SCHOTTKY. *Physik. Z.* **31**, 913–25(1930).—An electrode was placed on a Cu_2O layer which covered a Cu plate. The photoelec. current which flowed, without superimposed voltage, between Cu and the electrode was measured. If the Cu_2O is illuminated by a pencil of light parallel to the electrode, the photoelec. current decreases exponentially with the distance between the electrode and the pencil of light. The origin of the current is assumed to be the boundary between Cu_2O and Cu. The quant. formulation of the phenomenon is based on a chain conductor model, composed of series and parallel resistances. FRANK URBAN

The spectral distribution of the inner photoelectric effect in plastic deformed sodium chloride crystals. M. N. PODASHEVSKII. *Z. Physik* **65**, 799–805(1930).—The absorption curve of rock-salt plates, which were sensitized by irradiation with x-rays, is detd. before and after the material has been subjected to mech. stress. The max. of the curve is lowered and shifted toward the long waves by this treatment. In some cases this process has been found to be reversible. EGON BRETSCHER

Influence of the adsorption of cesium on salt layers on the photoelectric properties. J. H. DE BOER AND M. C. TEVES. *Z. Physik* **65**, 489–505(1930).—A CaF_2 suspension is sprayed on the wire of an incandescent lamp and the deposit sublimed *in vacuo* to the wall of the bulb. Cs is now distd. on to this base and the spectral absorption and the photoelec. emission are studied as functions of the thickness of the metal layer. The spectral absorption of Cs depends very much on the base on which it is placed. This shift of absorption is explained by the elec. field of the crystal lattice acting on the highly polarizable Cs atom. The max. photoelec. sensitivity of Cs on CaF_2 is found at 7000 A. U.; of Cs on BaF_2 at 7300 A. U.; but for Cs on Cs_2O it lies between 1 and 1.2μ. The sensitivity has been increased from 0.17 ma./lumen for the pure metals to 12.0 ma./lumen for Cs on Cs_2O. The sensitivity increases at first with increasing size of the alkali metal layer but diminishes again and attains later a const. value. E. B.

Use of x-rays in practice. BRANKO BOŽIĆ. *Arhiv hem. farm.* **4**, 194–212(1930).—A brief discussion and description of the modern methods of investigation of materials. J. KUČERA

Some remarks on the angular intensity distribution of continuous x-ray spectrum. III. YOSHIKATSU SUGIURA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) 15, 37–9(1930).—A correction to *C. A.* **24**, 3425. C. C. KLESS

Free electrons in metals and the role of the reflections of Bragg. L. BRILLOUIN. *J. phys. radium* [7], **1**, 377–400(1930); cf. *C. A.* **24**, 5600.—Math. When an electron beam penetrates a metallic crystal, abnormal de Broglie waves are formed, showing discontinuities in the energy. These are due to the periodic potential within the crystal and correspond to x-ray reflection from the lattice plane. The nature of the waves can be investigated by the perturbation method of Schrödinger. The waves corresponding to various electron levels can be specified and a level n gives waves of length approx. $2d/n$, where d is the lattice space. By simple transformations and use of an apparent numbering of the waves, the energy can be represented by a formula similar to that which is valid for free electrons in space. An apparent mass is also required which may become neg. This is similar to the apparent quantum no. in the Rydberg formula. If the electrons are considered as a completely degenerate gas, the de Broglie waves have a certain min. length. From this min., it is shown that selective reflection cannot take place for univalent metals of face-centered or body-centered cubic lattice. These are the metals with high elec. cond. For multivalent metals of cubic hexagonal and diamond-type structure, selective reflection can take place for their free electrons. G. M. MURPHY

Reflection of x-rays of long wave length. J. THIBAUD. *J. phys. radium* [7], **1**, 404(1930).—T.'s formula for the reflection of x-rays (*C. A.* **24**, 4453) reduces to that of Valouch (cf. *C. A.* **24**, 2372) and gives the same value for the limiting power. The

difference between the limiting angles as measured by T. and V. comes from the use of different kinds of glass. G. M. MURPHY

A vacuum spectrograph for precise measurements of x-rays of long wave lengths. CARL E. HOWE. *Rev. Sci. Instruments* **1**, 749–57(1930).—The app. has 4 special features: a slit system which excludes optical light and gives excellent collimation of the x-rays; a grating support by which the plane grating may be set at any angle or removed from the ray path without disturbing other adjustments; a set of 2 parallel plate-holders at a fixed distance apart and at right angles to the slits and an x-ray tube with interchangeable targets mounted on a micrometer slide by which the focal spot can be lined up with the slit system. J. H. MOORE

Remark on the paper of W. Busse: Extension and intensity of Debye lines or rings as function of the dimensions of the tube focus, the camera and the preparation. M. A. BREDIG. *Z. Physik* **65**, 430(1930); cf. *C. A.* **25**, 248.—Polemical. A round focus of an x-ray tube gives the same intensity as a linear one if the slit is parallel to the plane of the anode. EGON BRETSCHER

Röntgenspectroscopic measurements of the *L*-absorption of elements 74 tungsten to 92 uranium. ARNE SANDSTRÖM. *Z. Physik* **65**, 632–55(1930).—To obtain the wave length of the *L*-absorption edge with high precision, a Siegbahn spectrometer was used and the absorbing material brought between the slit and the photographic plate. The suitable size of the absorption layer has been calcd. so that the intensity difference on both sides of the edge is a max. The following results were obtained for the L_I, L_{II} and the L_{III} absorption edge (in X. U.) W: 1212.9, 1071.7, 1023.5; Re: 1175.5, 1035.4, 987.3; Os: 1139.0, 999.8, 955.8; Ir: 1103.8, 965.4, 922.3; Tl: 977.8, 841.9, 807.2; Pb: 949.2, 814.3, 781.2; Bi: 922.1, 787.8; U: 755.9; Th: 760.0, 629.3, 603.9, 720.8, 591.3, 568.0. EGON BRETSCHER

X-ray spectrum of the element 91—ekatantalum. I. *L* series. A. V. GROSSE. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, 402–4.—The element of at. no. 91, ekatantalum, was discovered. Forty mg. of its most stable isotope (protoactinium) was obtained. The method of prepn. will be described later. The *L* series of the spectrum was studied by the Siegbahn method, an x-ray spectrograph of the Bragg type being used. The oxide of the element, El_2O_5, was used for that purpose. The wave lengths of 21 lines of ekatantalum were detd. by comparison with those of Br, Sr, Mo, Ag and found to have λ's from 1088.5×10^{-11} to 586.6×10^{-11} cm. The only impurity of the prepd. oxide used was about 0.5% Ta_2O_5. J. G. TOLPIN

The scattering of x-rays by copper and silver. ALEXANDER RUSTERHOLZ. *Z. Physik* **65**, 226–32(1930).—The scattering function of metallic Ag and Cu is obtained from the photometrically detd. integral intensities of Debye-Scherrer lines. The scattering function of Cu agrees with the results of A. H. Armstrong (*C. A.* **24**, 1027) and the values for Ag are in accord with the scattering function calcd. on the bases of the Thomas-Fermi distribution of elec. density. EGON BRETSCHER

The structure of the *K*-radiation in the ultra soft x-ray region. MARTIN SÖDERMANN. *Z. Physik* **65**, 656–61(1930); cf. *C. A.* **25**, 24.—The x-ray emission lines of C (λ = 44.54 A. U.), B (λ = 67.71 A. U.), Be (λ = 115.7 A. U.) are shown to be simple, contrary to Faust (*C. A.* **23**, 3406; **24**, 5605). EGON BRETSCHER

Calculation of the electron affinity of the hydrogen atom. P. STARODUBROVSKII. *Z. Physik* **65**, 806–13(1930).—The Hylleraas method of approximation (*C. A.* **24**, 2951) is criticized. S. obtains in 4th approximation for the electron affinity of the H atom the value E = 16.40 ± 0.03 kg.-cal./mol. EGON BRETSCHER

Intensity of mercury lines excited by positive ions. D FRISCHE. *Proc. Iowa Acad. Sci.* **36**, 307–8(1929).—Observations were made concerning the intensity of lines of the Hg spectrum as excited by pos. ions. The results were compared with corresponding data on the electron spectrum given by previous observers. Intensity measurements were made with a microphotometer. W. G. G.

An extension of simple spectra. F. PASCHEN. *Sitzb. preuss Akad. Wiss.* **1930**, 574–8.—The ordinary simple spectra, the explanation of which is based on only a single electron, acquire an extension when several electrons are excited simultaneously. In the case of 2-electron spectra with the ground state $ns\ ns\ ^1S$ excitation of the latter type leads through $np\ np$, $np(n+1)s$, $np\ 3d$, etc., finally to double ionization as the limit of the extended spectrum. Examples are drawn from the He I, Be I and Al II spectra. W. F. MEGGERS

The relativity separations of the spectrum lines of hydrogen-like elements in parallel and crossed electric and magnetic fields. D. P. ROY-CHAUDHURI. *Z. Physik* **65**, 824–9(1930). EGON BRETSCHER

The influence of the breadth of the slit on the distribution of intensity of a spectral

line. P. H. VAN CITTERT. *Z. Physik* **65**, 547–63(1930).—The distribution of intensity across a spectral line depends not only on the diffraction of the spectral app. and the size of the slit, but also on the manner of illumination of the slit. EGON BRETSCHER

The shift of the hydrogen terms in strong electric fields. C. LANCZOS. *Z. Physik* **65**, 431–55(1930).—The Stark effect of H is calcd. for very strong fields It is shown that the usual series development of the perturbation calculus becomes divergent for strong fields. EGON BRETSCHER

The continuous spectra of the atom and of the molecule of hydrogen. D. CHALONGE AND NY TSI ZÉ. *J. phys. radium* [7], **1**, 416–25(1930).—When an uncondensed elec. discharge passes through H at several mm. pressure the secondary spectrum is emitted, and also a continuous spectrum of mol. origin with an energy max near 2350 A. U. (cf. *C. A.* **24**, 2050). When the discharges are condensed so as to suppress the secondary spectrum, the Balmer lines reach great intensity and the continuous spectrum changes and becomes purely at. In this case the energy distribution appears to be related to the Balmer and Paschen series; it is nearly uniform between the different wave lengths of each series but is much more intense in the 1st than in the 2nd The continuous spectrum has been photographed to about 9200 A. U. in the infra-red W. F. MEGGERS

Energy levels of atoms in an electric field. J. S. FOSTER. *Nature* **126**, 845 (1930).—Further exptl. evidence that Stark levels with equal m values do not intersect (cf. *C. A.* **24**, 5620) is found in some expts. on Ne (cf. *C. A.* **23**, 2363). Ishida's conclusion that the selection rule is broken is believed due to exptl. error due to an imperfect adjustment of the double-image prism with reference to the axis of the Lo Surdo tube. The unknown series lines he discovered are concerned with π components which vanish or become very weak as they pass the zero field positions and have been observed previously. ARTHUR FLEISCHER

New ultra-violet spectrum of helium. JOHN J HOPFIELD. *Astrophs. J.* 72, 133–45(1930).—The resonance series of He in the ultra-violet has been extended to 10 members, the first line being at 584.328 A. U and the 10th at 506.56 A. U. Continuous bands have been found superimposed upon at. lines and intense continuous spectra of mol. origin have been discovered in the interval 500-1125 A. U. This is the only strong continuous spectrum that has yet been found in the region 500 to 900 A. U. To account for the observed facts 2 distinct species of He mol. are postulated, one of which consists of loosely bound, practically unexcited atoms and the other is made by the union of 2 atoms, one or both of which are excited to the 2^3S metastable state. The former would be closely assocd. with the resonance lines and the latter is the source of the visible bands and of the 2nd continuous spectrum. The first absorption spectra to be obtained in the region 500 900 A. U. are those of O_2 and H_2 W. F. MEGGERS

Numerical calculation of the 2*S* terms of ortho- and par-helium. EGIL A. HYLLERAAS AND BJARNE UNDHEIM. *Z. Physik* **65**, 759-72(1930).—The energy of the ground term of ortho-He is found in abs. agreement with the exptl. value. The result for the 2*S* term of par-He differs 2.5% with respect to the total energy. E. B

Determination of the distribution of electricity in the lithium atom. B. ASAKATSU AND PAUL SCHERRER. *Helv. Physica Acta* **3**, 428 35(1930).—The scattering of x-rays from fine Li powder is investigated to det. the scattering function of the Li ion (as the valency electron may be considered to be free). The lattice of Li is found to belong to the cubic face-centered system and to possess the dimension $a = 3.5$ A. U. The atom scattering curve F is obtained from the photometrically detd. intensities after the elimination of the structure factor and the temp. factor. To represent the latter the Debye-Waller formula is used with the characteristic temp. $\theta = 510°$ as detd. by Simon. The F curve thus obtained experimentally agrees excellently with Brindley's values (*C. A.* **24**, 3162) obtained on the basis of wave mechanics, if zero point energy is taken into account. Cu K_α radiation was used for the expts. E. B

The hyperfine structure of bismuth. P. ZEEMAN, E. BACK AND S. GOUDSMIT *Z. Physik* **66**, 1–10(1930). **Appendix.** E. BACK AND J. WULFF. *Ibid* 10–12. The hyperfine structure of the Bi arc lines (10 components) shows that the Bi nucleus possesses an angular momentum of $(9/2)(h/2\pi)$. The intensities agree remarkably well with those calcd. from Pauli's theory of nuclear spin. EGON BRETSCHER

The Paschen-Back effect of the hyperfine structure. S. GOUDSMIT AND R. F. BACHER. *Z. Physik* **66**, 13–30(1930).—The formulas of the Paschen-Back effect for ordinary multiplets are generalized so as to include also the hyperfine structure due to the nuclear spin. These relations are applied to the Zeeman effect of the hyperfine

structure of Bi, which has been studied by Back and Wulff (cf. preceding abstr.). EGON BRETSCHER

The Zeeman effect of the hyperfine structure of λ = 3775 A. U. of thallium. E. BACK AND J. WULFF. *Z. Physik* **66**, 31-48(1930).—The Goudsmit and Bacher formulas (cf. preceding abstr.) for the Zeeman effect of the hyperfine structure are verified experimentally in the case of λ = 3775 A. U. of Tl. The agreement with theory is perfect for weak, medium and strong fields. EGON BRETSCHER

The arc spectrum of carbon (C I). F. PASCHEN AND G. KRUGER. *Ann. Physik* [5], **7**, 1-8(1930).—The arc spectrum of C was observed in the light emitted by hollow cathodes when a discharge was passed through a stream of He. The observed wave lengths lie in the ultra-violet between 2584 A. U. and 1112 A. U. These lines represent groups of series as follows: (1) series of $2pns\,^3P$, $2pnd\,^3D$, $2pnd\,^3P$ terms, all with $2p^2\,^3P$ as limit; (2) series of $2pnd\,^1F$, $2pnd\,^1D$, $2pnd\,^1P$ terms with $2p^2\,^1D$ as limit; and (3) a series of $2pns\,^1P$ terms with $2p^2\,^1D$ and $2p^2\,^1S$ as limits. Inter-series lines have also been found. Calcn. of the series gives 90,836 cm.$^{-1}$ as the value of the ground term $2p^2\,^3P_2$, corresponding to an ionization potential of 11.21 v. for the neutral C atom. The tables contain the term values and classifications of the observed lines. C. C. K.

Large displacements in the spectra of ionized nitrogen. KWAN-ICHI ASAGOE. *Science Reports Tokyo, Bunrika Daigaku* **B1**, 47-61(1930).—The behavior of the spectra of ionized N was studied when excited by heavily condensed discharges in air at 7 mm and by sparks between metallic electrodes in air at one atm. Lines belonging to N II were found to be shifted redward. These shifts have been measured and have been correlated with the terms from which the lines arise. On the other hand lines of N III appear to be shifted toward the violet, although the displacements, if real, are very small. C. C. KIESS

The oxygen spectrum O I. F. PASCHEN. *Z. Physik* **65**, 1-3(1930); cf. *C. A.* 24, 5621.— A powerful discharge under specified conditions gives rise to 3 new lines observable in the pos. column. They have the following wave lengths and relative intensities (J): 6500.03 A. U. (J = 5) 4664.07 A. U. (J = 3), 3691.0 A. U. (J = 1) and correspond to the transitions: $(2p)^4\,^1D_2 \longrightarrow (2p)^4\,^3P_{2,1,0}$. EGON BRETSCHER

Spectrum of singly ionized chlorine (Cl II). KIYOSHI MURAKAWA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, 41-67(1930).—The spectrum of Cl II was obtained by passing a condensed discharge through a Geissler tube with powd. NaCl on one electrode. Wave lengths were measured on grating and quartz prism spectrographs extending from 6759 A. U. in the red to 2321 A. U. in the ultra-violet. Many of these lines have been classified as combinations between quintet, triplet and singlet terms derived from ^4S, ^2D and ^2P of Cl III. From series of terms the ground state of Cl II has been fixed as $^3P_2$ = 187249 cm.$^{-1}$, which gives an ionization potential of 23.22 v. The numerical details are given in the tables. C. C. KIESS

New resonance series of selenium. HALINA GRÜNBAUM. *Bull. intern. acad. Cracovie* **1929A**, 611 5(in French); *Sprawozdania i Prace Polskiego Towarzystwa Fizycznego* **4**, 357 63(1929)(in Polish); cf. B. Schmidt, *C. A.* **23**, 1056.—Selenium (Se) vapor excited by waves of the length 4811 and 4680 A. U. (Zn spark) and 4678, 4663 and 4113 A. U. (Cd spark) shows a faint fluorescence which cannot be photographed. If, however, the vapor is excited by Ca spark of the wave length 3934 and 3969 A. U., 2 distinct resonance series appear. They become visible at 350° and show great intensity at 600°; the d. of the vapor corresponds to a satn. at 320°. The observed resonance series are in concordance with Rosen's (*C. A.* **21**, 2846) formula: $\nu = A - 397.5\,n - 1.32\,n^2$, where A = 28,517 for 3934 A. U., and 28,292 for 3969 A. U. The absorption of the rays corresponds to the passage from the normal state of the pool n = 8 to the excited state n' = 5 for 3934 A. U. and from n = 8 to n' = 4 for 3969 A. U. The results permit extension of the scheme of the known Se series. J. WIERTELAK

The spectrum of trebly ionized cerium (Ce IV). J. S. BADAMI. *Proc. Phys. Soc. London* **43**, 53-8(1931).—The spectrum of the condensed spark of Ce was investigated in the ultra-violet and doublet combinations similar to those in Cs I, Ba II and La III spectra were found. Eight Ce IV lines ranging in wave length from 2778.23 to 1853.15 A. U. are classified; these involve 8 spectral terms, the lowest of which is $^2D_{3/2}$, 210,895.3 cm.$^{-1}$ corresponding to an ionization potential of 26.0 v. W. F. MEGGERS

The spectrum of doubly ionized arsenic. K. R. RAO. *Proc. Phys. Soc. London* **43**, 65-71(1931).—The doublet system of As III published by Lang (*C. A.* **23**, 2101) has been amended and extended in the light of new observations. Thirty-eight lines

(7240 to 603.79 A. U.) have been classified; term values have been evaluated and an ionization potential of about 28.19 v. is deduced for As^{++}. W. F. MEGGERS

A spectrophotometric and spectroscopic study of Phi Persei. HERBERT F. SCHIEFER. *Proc. Iowa Acad. Sci.* **36**, 281–93(1929).—A standard calibration curve for the reduction of photograms made with the Moll self-registering photomicrometer was prepd. and an intensive study of the H lines observed in the spectrum of Phi Persei was made. A short bibliography is appended. W. G. G.

Absorption lines of sulfur (S III and S II) in stellar spectra. F. E. ROACH. *Astrophys. J.* **72**, 191–8(1930). W. F. MEGGERS

The coexistence of stellar and interstellar calcium lines in the eclipsing binary U Ophiuchi. OTTO STRUVE. *Astrophys. J* **72**, 199–201(1930). W. F. MEGGERS

Heights in the chromospheres. S. A. MITCHELL. *Astrophys. J.* **72**, 146–86 (1930).—A spectrum study; cf. *C. A.* **24**, 2670. W. F. MEGGERS

Simple relations of molecular spectra with the structure of the molecule. H. DESLANDRES. *Compt. rend.* **191**, 1404–7(1930).—An attempt to show that infra red frequencies derived from Raman-effect data and residual rays are expressible as multiples of d_1/t, where t is a small whole no. and $d_1 = 1062.5$ cm.$^{-1}$. Cf. *C. A.* **23**, 2884, 5005. W. F. MEGGERS

The natural breadth of line of the radiation of a harmonic oscillator. V. WEISSKOPF AND E. WIGNER. *Z. Physik* **65**, 18–29(1930).—Previous calcns. (*C. A.* **24**, 5602) are extended to cover the harmonic oscillator. Perfect agreement with the classical formula results. EGON BRETSCHER

Intensities and summation rules of normal quadripole multiplets. A. RUBINOWICZ. *Z. Physik* **65**, 662–76(1930). EGON BRETSCHER

The validity of the Hill and van Vleck intensity formulas for the NO γ-bands. R. SCHMID, T. v. NEUGEBAUER, D. v. FARKAS AND CHARLOTTE BARABAS. *Z. Physik* **65**, 541–6(1930); cf *C. A.* **24**, 2050. —The intensity sequence of the $^2\Sigma_{(b)} \longrightarrow {}^2\Pi_i$ transitions of the branches of the NO γ-band is correctly given by the Hill-van Vleck formula (*C. A.* **23**, 34) if the relation for the "general intermediate case" is used. EGON BRETSCHER

The frequency dependence of Raman's scattered radiation. L. S. ORNSTEIN AND J. REKVELD. *Z. Physik* **65**, 719–22(1930).—It is shown that the the method by which G. S. Sirkar (*C. A.* **25**, 31) obtained a deviation from the usual λ^{-4} law is very objectionable. Correct scattering measurements on CCl_4 show that the absorption is negligible in the region of the Hg lines 4358 to 3152 A. U. (in contradistinction to Sirkar). EGON BRETSCHER

Experimental result on the scattering of light in the range of small angles. G. I. POKROVSKII. *Z. Physik* **65**, 130–2(1930).—A beam of light passes through a layer of *water* or an *alcohol-water mixture* and the light scattered is received on a photographic plate, the primary beam being removed by interposition of a little screen. The intensity of the light scattered, as function of the distance R from the primary beam is obtained photometrically and it is shown to vary proportionally with $1/R$ as required by the author's theory (*C. A.* **24**, 2923). EGON BRETSCHER

Investigation of the Raman effect of crystals. CLEMENS SCHAEFER, F. MATOSSI AND H. ADERHOLD. *Z. Physik* **65**, 289–318(1930); cf. *C. A.* **24**, 552.—*Calcspar* gives Raman lines corresponding to the following frequencies: 65, 35.5, 14, 9.2, 6.06 and 5.74μ. The latter is a combination frequency corresponding to λ = 14.16μ and 9.1μ. Higher temp. gives rise to an anti-Stokes line corresponding to λ = 9.2μ. *Aragonite* possesses the same Raman spectrum. *Magnesite* has an optically inactive frequency at 1–9.2μ. *Cerussite* exhibits internal oscillations at 9.5, 7.34, 6.78μ and external at 56.5, 68.5, 85, 98, 5, 135 and 169μ. $NaNO_3$ shows frequencies corresponding to 5.96, 7.2, 9.35, 13.75, 54 and 105μ; $Ba(NO_3)_2$ 9.56μ; $NaClO_3$ 9.75, 10.15, 10.3, 10.7, 16, 20.6, 80μ; $NaBrO_3$ 11.90, 12.5, 27, 28μ; $Cd(BrO_3)_2$ 12.7μ; $BaSO_4$ 8.80, 10.15, 15.6, 16.3, 21.7μ. $KLiSO_4$ and *gypsum* give the well-known frequencies corresponding to the SO_4 radical and 2 lines resulting from the water of crystallization. *Magnesium ammonium selenate* (λ = 12μ), *ammonium phosphate* (λ = 10.85μ) and *ammonium chlorate* have also been studied, though with less satisfactory results. It is emphasized that the inactive infra-red frequency appears mostly with great intensity. Two active and 2 inactive frequencies have generally been observed in compds. of the type XY_4. L. B.

The polarization of the Raman radiation of crystals. CLEMENS SCHAEFER, F. MATOSSI AND H. ADERHOLD. *Z. Physik* **65**, 319–29(1930); cf. preceding abstr.—The direction of polarization of the Raman lines from crystals (*calcspar*, *gypsum* and $NaNO_3$) as a function of the direction of the incident light with respect to the crystal axes is

idied. No agreement is found with the Leontowitsch theory (*C. A.* **24**, 5631).
EGON BRETSCHER

Raman spectra of some isomers. H. MLODZIANOWSKA. *Z. Physik* **65**, 124–9 930).—Raman lines of the *o-*, *m-* and *p-dichlorobenzenes*, the *nitrotoluidines* and the *uidines* are listed. The frequency shift $\Delta\nu$ is found to decrease in a regular way passing from the *o*-dichlorobenzene to the meta and para compds. E. B.

The Raman effect of crystalline and dissolved sulfates and carbonates. NIKOLAUS EMBIRIKOS. *Z. Physik* **65**, 266–9(1930).—The inactive frequencies of the following solid sulfates and carbonates are detd.: $Li_2SO_4{\cdot}H_2O$ ($\Delta\nu$ = 1003.1 cm.$^{-1}$), K_2SO_4 92.1), $(NH_4)_2SO_4{\cdot}H_2O$ (990), $MgSO_4{\cdot}7H_2O$ (986.8), $CaSO_4{\cdot}2H_2O$ (1010.1), $ZnSO_4{\cdot}H_2O$ (9920), $CdSO_4 3/8\ H_2O$ (1003.2), $MnSO_4{\cdot}5H_2O$ (993.9), $CaSO_4$ (1087.6). A coarse ystal powder of these compds. was used and benzene was added to increase the transrency. Most of the salts (and in addn. Na_2CO_3 and K_2CO_3) were also studied *N* and 2 *N* aq. soln. The frequency shift was generally smaller in soln. than for ie solid substance. The Raman lines of the crystals become more diffuse with increasg no. of mols. of water of crystn. EGON BRETSCHER

The polarization of Raman lines: some hydrocarbons. S. BHAGAVANTAM. *Indian Physics* **5**, 603–8(1930); cf. *C. A.* **24**, 5230.—The polarizations of the Raman lines benzene, cyclohexane and pentane were measured. Those showing the most comete polarization are 992 of benzene and 800 and 992 of cyclohexane. These lines present inactive oscillations of the mols. and appear faintly or not at all in the infrad absorption spectra. All the other Raman lines of benzene are nearly completely ipolarized, whereas those of cyclohexane and pentane are well polarized. C. C. K.

The origin of the continuous spectra in Raman scattering. N. N. PAL AND P N. EN GUPTA. *Indian J. Physics* **5**, 609–10(1930).—When BzH was kept colorless by ntinuous circulation in a Woods tube it gave sharp Raman lines without a continuous pectrum. When the circulation was stopped photochem. action caused the appearance the BzH of a yellow product which in turn gives a continuous spectrum extending ell into the red. C. C. KIESS

The characteristic Raman frequencies of radicals in different chemical combinaons. N. N. PAL AND P. N. SEN GUPTA *Indian J. Physics* **5**, 611–4(1930).—A review f the frequencies attributed to the CN radical in different types of compds. shows a nge from 2266 for org compds., to 2066 for some complex cyanides. The nature f the bond rather than the mass of the substituent radical seems to be the predominant ictor in the detn. of the frequency. C. C. KIESS

Further studies on the Raman spectrum of diamond. S. BHAGAVANTAM. *Indian . Physics* **5**, 573–86(1930).—With larger and better specimens of diamond than those sed previously (*C. A.* **24**, 4987) the following faint Raman lines were observed in addn. o the strong 1332 line previously reported: 1382, 1431, 1480, 1585, and the anti-Stokes ne 1332. These correspond to infra-red absorption frequencies observed by Reinober, although the frequency corresponding to 1332 is weakest in absorption and herefore represents an optically inactive frequency of the diamond mol. In the fluorescent band system of the diamond 2 more components have been found, making 5 in ll. The intensity of 1332 was found to be about 6 times that of the 992 line of C_6H_6. C. C. KIESS

Raman effect with cadmium arc excitation. P KRISHNAMURTI *Indian J. Physics* **5**, 587–91(1930).—A Cd-Sn alloy arc has been found to be a suitable source or the excitation of Raman spectra. The Cd lines 5085.8 and 6438.5 A. U. are particularly effective. With this source the colored crystals $FeSO_4.7H_2O$ and $NiSO_4.7H_2O$ failed to show a line corresponding to the absorption line at 10μ. But the crystals showed the previously observed Raman lines and a new one corresponding to a shift of 183 cm.$^{-1}$. C. C. KIESS

Further investigations on the intensities of lines in Raman spectra. S. C. SIRKAR. *Indian J. Physics* **5**, 593–601(1930).—To test the 4th power law for Raman lines having large shifts the abs. intensities of the displaced lines of cyclohexane (2853 and 800) and of C_6H_6 (3080 and 990) were detd. by a method of photographic photometry. In harmony with previous results (*C. A.* **25**, 31) it was found that the deviation from the 4th power law is more for lines excited by ultra-violet than by visible lines, and that the deviation is greater for lines of greater shift. C. C. KIESS

Forms of oscillation of the benzene ring in Raman effect. S. BHAGAVANTAM. *Indian J. Physics* **5**, 615–31(1930).—From the theory of the vibrations of an elastic solid circular ring it is shown that the vibrations of a hexagonal ring consist of 6 flexural oscillations, 3 in the plane of the ring and 3 perpendicular to it. The Raman frequencies 607, 851, 992 and 1181 of C_6H_6 are attributed to the hexagonal C ring. Of these the

most intense is 992, which also appears in the Raman spectra of various compds. contg. the C_6H_6 nucleus. It is nearly completely polarized and appears only feebly in the infra-red absorption spectrum, being optically inactive because it represents an oscillation in which the 6 C atoms move tangentially, 3 at alternate corners moving in one phase, the other 3 in the opposite phase, so that the elec. moment of the mol. does not change. The frequency 607 represents an alternate expansion and contraction of the hexagon, whereas 851 and 1181, which agree with infra-red absorption bands, represent unsym. extensional oscillations. Long exposures have revealed 3 new Raman frequencies of C_6H_6 of 694, 1970 and 2181 cm.$^{-1}$, of which the first 2 agree with infra red bands. C. C. KIESS

Raman spectra of inorganic crystals. I. Substances containing XO_3 and XO_4 groups. P. KRISHNAMURTI. *Indian J. Physics* 5, 633–50(1930).—The crystal method was employed to det. the Raman spectra of $NaClO_3$, $KClO_3$, $Ba(ClO_3)_2.H_2O$, $NaBrO_3$, $KBrO_3$, KIO_3, HIO_3, $NaClO_4.H_2O$, NH_4ClO_4, KIO_4, $3(NH_4)_2O.7MoO_3.4H_2O$ and $Na_2WO_4.2H_2O$. The principal Raman shift 930 of the chlorates is represented by 2 shifts, 770 and 842, in the bromates, and by 4, 733, 751, 784 and 808, in the iodates. All the frequencies observed for the chlorates are active and correspond to observed infra-red absorption bands. Aq. solns. of the crystals studied give Raman lines in the same positions. The perchlorates give Raman lines at 462, 633 and 933, which remain unchanged in aq. solns. The Raman lines of KIO_4 are 794 and 841, which are altered in aq. solns. The molybdate gives the shifts 932 and 880, and the tungstate gives the shift 928, all unchanged in aq. solns. C. C. KIESS

Raman spectra of inorganic crystals. II. Some hydroxides, cyanides and thiocyanates. P. KRISHNAMURTI. *Indian J. Physics* 5, 651–62(1930).—The Raman spectra of NaOH, $Sr(OH)_2.8H_2O$, $Ba(OH)_2.8H_2O$, NaCN, $Hg(CN)_2$, $K_4Fe(CN)_6.3H_2O$, KCNS, NH_4CNS and $Ba(CNS)_2$ were observed by the crystal method. An aq. soln. of $KAg(CN)_2$ was also examd. The shift 3630 was found for the OH ion, which corresponds to the 2.66μ absorption band of water vapor. The principal frequency of CN shows a progressive change through a series of compds., being 2085 for NaCN and 2192 for $Hg(CN)_2$. These frequencies are affected but little in soln. For the CNS ion 2 Raman shifts were observed, a stronger one of about 2050 cm.$^{-1}$ due to the ion S–C–N and the other of about 750 cm.$^{-1}$ due to the S–CN oscillation. C. C. KIESS

The relative intensities of different Raman lines due to different exciting frequencies. S. C. SIRKAR. *Indian J. Physics* 5, 663–8(1930).—The intensities of the 2 very close Raman lines 1342 and 1582 scattered by nitrobenzene have been measured under excitation due to the Hg lines 4358 and 5461 A. U. The intensity ratios 1.59:3.1 and 6.5:2.74, resp., have been found. The abnormal intensity with which one of the lines corresponding to the active frequency of the NO_2 group is scattered is attributed to the partial absorption of the exciting line 4358 by the NO_2 ion. C. C. KIESS

Measurements on rock salt in the infra-red to test the theory of dispersion. M. CZERNY. *Z. Physik* 65, 600–31(1930); cf. *C. A.* 24, 1292.—The refractive index n and the absorption coeff. x of *rock salt* and *sylvine* are obtained from the measurements of transparency and power of reflection. Beside the well known max. of reflection at 52μ for rock salt and 62μ for sylvine, secondary ones are found at 39μ and 46μ resp. The values of n and x are fitted into the equation of dispersion consisting of 2 terms. A discrepancy is observed on the short-wave side of the proper frequency where the ordinary dispersion equation does not satisfactorily represent the observations. *Exptl. method:* grating and method of residual rays. To obtain thin plates of NaCl (sic) a special app. has been constructed permitting the scraping of the crystals with a razor blade to produce the necessary size. EGON BRETSCHER

Structure of resonance line groups of sulfur vapor. P. SWINGS. *Bull. internat. acad. polonaise* **1929A**, 616–20(in French); cf. *C. A.* 24, 5626.—S. repeats his previous investigations (*C. A.* 24, 3169, 4221, 5226) on the resonance spectrum of S_2 vapor with greater accuracy, using very strong light and high dispersion (about 1 A. U. per mm.). Four doublet series, *A*, *B*, *C* and *D*, are produced by Hg light of the wave length 3132, 3126, 2968 and 3655 or 3650 A. U. *D* represents several line doublets with distances of the components $\Delta = 34$ cm.$^{-1}$ and differences in the av. frequency about 670. From theoretical considerations it is concluded that *D* corresponds to quantum no. 4, while *A*, *B* and *C* correspond to quantum no. 2, being long doublet series with $\Delta = 18, 16, 8$ and 16 cm.$^{-1}$, resp. In addn. to groups of strong intensity one observes a certain no. of faint rays; those for 3132 A. U. are given. With a feeble dispersion this group appears to consist of 5 rays of equal intensity. Different pressures and temps. cause differences of the resonance intensity, which are very pronounced in the case of *A* and *B*. J. WIERTELAK

Extinction coefficients of the mixtures of chromates and dichromates. N. R. TAWDE AND G. R. PARANJPE. *Indian J. Physics* **4**, 533–8(1930).—A measurement of extinction coeffs. of mixts. of chromates and dichromates by the Nutting photometer in conjunction with a spectroscope is used to est. the percentage of chromate and dichromate in the presence of each other. H. W. WALKER

The absorption of ultra-violet light by methoxybenzoic acid. ANATAZY BORYNIEC AND L. MARCHLEWSKI. *Bull. intern. acad. polonaise* **1929A**, 631–5(in English).—As formerly shown, *p*-derivs. of benzene absorb ultra-violet light much more strongly than *m*- and *o*-derivs. (cf. *C. A.* **24**, 2052). On the basis of this peculiarity one could assume a quinoid structure of the *p*-compds. It has been found, however, that *p*-methoxybenzoic acid behaves in the same manner as the free acid. The strong absorption of the *p* derivs. remains, therefore, unexplained. *o*-Methoxybenzoic acid, m. 98.5–99°, in aq. soln. obeys Beer's law. The spectrum shows 2 bands at 2850 and 2300 A. U. and is almost identical with that of salicylic acid, which also shows 2 bands at 2950 and 2295 A. U. *p*-Methoxybenzoic acid, m. 184.2°, in EtOH obeys Beer's law, but shows only one band at 2535 A. U. The extinction curves of both substances, together with those of *m*- and *p*-hydroxybenzoic acids are given in a diagram. J. WIERTELAK

Residual luminescence of photoluminescent crystals and microcrystals in the infra-red. F. MARTIN. *J. phys. radium* [7], **1**, 401–3(1930).—After being kept in darkness for 6 months, various substances were illuminated with infra-red light. The residual luminescence was observed with the eye and with a photoelec. cell. The intensity of the luminescence varies widely among the substances studied and when the duration of reëmission of light falls to 10^{-8} sec., the extinction effect, fugitive illumination and residual luminescence all disappear. The last 2 effects seem to be 2 aspects of the same phenomenon. G. M. MURPHY

The phenomena of ionization of gases during photochemical reactions in solid bodies. P. P. LAZAREV AND N. L. RODZEVICH. *Compt. rend. acad. sci. U. R. S. S.* 1930A, No. 5, 105–6.—In photochem. reactions in certain dyes held suspended in a gaseous medium, the neg. charges appearing on the gas mols. depend on the nature of the gas. This effect is multiplied considerably (sometimes 100 and more %) in gases which cause fading of the dye. It is also greater when a layer of dye spread out on a quartz plate is illuminated from the side exposed to the gas than from the side adjacent to the quartz plate. S. L. MADORSKY

The photochemical reaction between oxygen and hydrogen chloride. ARTHUR J. ALLMAND AND REGINALD G. FRANKLIN. *J. Chem. Soc.* 1930, 2073–92.—Cl_2 can be formed and destroyed in concd. aq. HCl soln. contg. dissolved O_2 (according to: $4HCl + O_2 \rightleftharpoons Cl_2 + 2H_2O$) by ultra-violet light of wave lengths 254–365 mμ. A condition of true equil. in this reaction is reached at the stationary state, the cessation here of the oxidation of the HCl soln. resulting from the Cl_2 formed. With increasing HCl concn. the Cl_2 concn. required at the stationary state increases, being 0.08×10^{-3} *N* Cl in 5.5 *N* HCl soln. and 1.6×10^{-3} *N* Cl_2 in 11 *N* HCl. Light of 250–270 mμ causes the formation of Cl_2 at concns. below the stationary state, and causes the disappearance of Cl at concns. above this. Again, those wave lengths which induce the Cl_2 reaction at concns. above the stationary state have no such action below this. In the gaseous state HCl is oxidized only very slightly by O_2 in light from a quartz-Hg lamp, but the reaction goes nearly to completion in the sunlight. The reaction is sensitized by Cl_2 and retarded by the removal of H_2O vapor. The "gaseous" oxidation is believed to take place in a film of concd. aq. HCl formed on the walls of the contg. vessel. The quantum efficiency of the reaction in the aq. soln. at 260 mμ is about 0.2, decreasing rapidly with increasing wave length. J. BALOZIAN

Studies on the photosensitizing action by iodine; isomeric transformation of allo-cinnamylideneacetic acid into the normal form in methanol, ethyl alcohol, chloroform, and in mixtures of alcohol, chloroform and water. J. C. GHOSH, D. N. DAS-GUPTA, N. C. ROY AND H. K. CHATTERJEE. *J. Phys. Chem.* **34**, 2771–81(1930).—The authors summarize the results of previous studies on the above transformation when I is the photocatalyst. For the same solvent, excitation by green light is the most effective, then blue, yellow and red in decreasing order of effect. For the excitation by the same quality of light, the solvents decrease in the order of MeOH, EtOH, mixts. of EtOH and H_2O, and mixts. of $CHCl_3$ and MeOH. In $CHCl_3$ the velocity is negligible as compared with solvents contg. the OH group. The theory of the photocatalytic action of I is discussed. H. W. LEAHY

The fluorescence of cod-liver oil. C. A. MOREHOUSE. *Proc. Iowa Acad. Sci.* **36**, 297(1929).—The fluorescence was produced by the radiation from a Cooper Hewitt quartz Hg vapor lamp. A Corex "A" blue-purple filter was used to filter out that

part of the spectrum of the exciting light in which the fluorescence appeared. The filtered light, which was almost entirely in the ultra-violet, was focused directly on the surface of the cod-liver oil by means of a quartz lens. The fluorescence spectrum was detd. by means of a const.-deviation glass-prism spectrograph. A bright band was obtained for the cod-liver oil in the region extending from 546 mμ to 436 mμ. With a 1% soln. of the cod-liver oil in alc., the same band was found but it was much fainter. A soln. of cholesterol in alc. also gave a fluorescence band in this same region, *i. e.*, 546 mμ to 436 mμ. This cholesterol had been previously tested and shown to be capable of being activated by ultra-violet light. W. G. GAESSLER

Electrothermic zinc. A. WALTER. *Trans. Am. Electrochem. Soc.* **59**, preprint, 5 pp.(1931); cf. *C. A.* **24**, 5639.—The development of electrothermic Zn during the past 30 yrs. is briefly reviewed, with particular emphasis on the many difficulties to be overcome before the process became commercial. The smelting is carried out in an arc furnace of the Heroult type. The operation is continuous and comparatively simple. The Zn vapors pass out of the furnace and into a condenser, from which the Zn is tapped at regular intervals. The crude 93–95% Zn thus produced is refined by resublimation in a sep. elec. furnace. The final product averages 99.85% Zn. The process outlined is applicable to all kinds of Zn ores, and high recoveries of accompanying metals such as Cu, Pb, Au and Ag are possible. The total elec. energy consumption amounts to 5600 kw.-hr. per 1000 kg. of 99.85% slab Zn. C. G. F.

Electrothermic zinc. G. NEWTON KIRSEBOM. *Eng. Mining J.* **131**, 55(1931).—A brief review. W. H. BOYNTON

A new experiment to demonstrate the "pinch" effect. E. BLAICH. *Elektrotech. Maschinenbau* **48**, 1083–5(1930).—An expt. is described which served to demonstrate that in an elec. furnace in which the molten metal serves as a conductor, a contraction or pinching of the cross section of the metal occurs at certain points and is accompanied by violent local currents in the molten metal. This turbulence produces a pressure effect at certain spots which can be demonstrated and measured. This phenomenon is said to be due to electromagnetic forces. H. STOERTZ

Electrolytic copper refining at Mount Lyell, Tasmania. WM. HART. *Eng. Mining J.* **131**, 3–7(1931).—The refinery at Queenstown, Tasmania, has been in operation for 25 years. A plan, photographs and sections of the electrolytic refinery are shown, and the operations outlined. The method of starting operations is probably unique, because no attempt is made to heat the electrolyte, the current being turned on when the soln. is cold. The addn. of 44 cells will increase the capacity to 13,000 long tons per annum.
W. H. BOYNTON

Cathodic forms of electrolytic tin. F. FOERSTER AND H. DECKERT. *Z. Elektrochem.* **36**, 901–23(1930).—Crude *m*-cresolsulfonic acid in the electrolysis of a H_2SO_4 soln. of $SnSO_4$ can repress the tendency of the Sn to form needles growing perpendicular to the surface of the cathode, and to form the Sn ppt. in a smooth and even surface. The by-products formed in the sulfonation of *m*-cresol influence the sepn. of the Sn because they are absorbed by the ppt. The amt. and nature of the by-products depend upon temp. and time of sulfonation. Above 120° colloidal by-products are also formed. When the concn. of impurities is low, the Sn deposit is needle-like to spongy. As the concn. increases, the deposit becomes granular or smooth, and when high the crystals become fine and arranged in unordered patterns. Finally the plated Sn becomes structureless and milk-white in color and a point is reached when colloidal material ppts. with the Sn. The absorption is less at high temps. and greatest at low temps. JOHN R. HILL

A comparative measurement of throwing power in electroplating practice. L. K. WILSON. *Metal Ind.* (N. Y.) **28**, 522–3(1930).—The interest of the com. electroplater lies mainly in the color, appearance and covering power of the plates produced in various electrolytes, rather than in comparative current efficiency. An electrolyte which does not "throw" well leaves the hollows and depressions of a cathode unplated, or else "burns" the projecting portions before the bottoms of the depressions are coated. With reference first to a no. of methods for measuring the throwing power of plating solns. (*C. A.* **16**, 2270; **17**, 3457; **18**, 3147; **20**, 1359; **24**, 2380, 3953, 4990), the article describes a method in which test tubes made of Fe or brass, or with a thin flash of Cu, Sn, Zn, Pb, Cd or other desired metal to be coated, are placed in an instrument and immersed in a plating tank. At the end of the plating period (2–20 min.), the depth of throw is measured by a throw scale calibrated every 0.05 in. and numbered from 1 to 25; comparative data of value to com. and exptl. platers are thus obtained. C. L. W.

The electrodeposition of silver-cadmium alloys. COLIN G. FINK AND BASIL G. GERAPOSTOLOU. *Metal Ind.* (N. Y.) **28**, 519–21, 562–3(1930).—From solns. of the complex cyanides of Ag and Cd, Ag-Cd alloys were deposited. The effects upon the compn. of the deposits caused by changes in the conditions of deposition were investi-

gated and the following conclusions drawn: Increased Cd/Ag ratio in the bath causes an increased Cd/Ag ratio in the deposit. Increased c. d. causes an increase in Cd in the deposit. Increased temp. decreases the Cd content of the deposit and makes the deposit more brittle. Agitation causes increased anode corrosion and decreased Cd content of the deposit. Microscopic investigation revealed a mixt. of a Ag-rich solid soln. (or else pure Ag) and a Cd-rich solid soln. Ag-Cd alloys of high Ag content do not seem to resist tarnish any better than pure Ag, when exposed to the action of H_2S.

CURTIS L. WILSON

Electrodeposition of chromium-iron alloy. G. FUSEYA AND K. SASAKI. *J. Soc. Chem. Ind. Japan* **33**, Suppl. binding 474–82; *Chem. News* **141**, 407–8(1930); cf. *C. A.* **25**, 1195.—Expts. were performed to find the best conditions of electroplating stainless iron, *i. e.*, iron contg. more than 16% Cr. A mixed soln. of $FeSO_4$ and $Cr_2(SO_4)_3$ was finally used. A soln. of violet $Cr_2(SO_4)_3$, prepd. from Cr alum, changed partly into a green form in soln. An acidity a little less than that produced in the formation of the green form of $Cr_2(SO_4)_3$ proved the best for the deposition of bright Cr; higher acidity caused H evolution; too low an acidity caused the inclusion of much hydroxide in the deposit. Free H_2SO_4 (0.05–0.1 mol.) was the most suitable acid; NaOH was added to the soln. until the required acidity was attained. To maintain this acidity, boric, oxalic or tartaric acid could be used. The free H_2SO_4 was detd. by pptg. with acetone all salts and hydroxide present, filtering and distilling off the acetone from the filtrate. Values for acid content agreed fairly well with those obtained colorimetrically with thymol blue. In practice two anodes, Fe and magnetite, had to be used and $Cr(OH)_3$ was added at intervals to replace the Cr deposited. For about 20 min. the current efficiency remained almost const., after which it decreased (because of the low overvoltage of the alloy), the Cr content of the alloy also decreasing. The higher the c. d., the greater was the Cr content of the alloy and also the current efficiency. The greater the acidity of the soln., the smaller was the Cr content of the deposit and also the current efficiency. Temp. had an effect similar to that of acidity, because the H over voltage became smaller as the temp. rose. An increase in $FeSO_4$ concn. increased the current efficiency and lowered the Cr content of the deposit. The deposits contained always some oxide (up to 10%). The amount became larger, the larger the c. d. and the lower the acidity; it decreased with increase in temp. The deposits appeared cloudy or dark when the O content was more than 5%. The deposit resisted the action of satd. solns. of NaCl, NH_4Cl, oxalic or tartaric acid, of a concd. soln. of acetic acid, or a 6 *N* soln. of NH_4OH. The Cr produced at room temp. with c. ds. below 15 amp. sq. dm. had a body-centered cubic form; with c. ds. above 18 amp. per sq. dm. a hexagonal close-packed form was obtained. For the alloy deposition not more than 15 amp. sq. dm. was used; the deposit was a solid soln. of the body-centered cubic form, having nearly the same structure as have the alloys produced by fusion. Bright deposits of metallic luster are best obtained from a soln. of 1.0–2.5 mol. Cr, 0.5 mol. Fe and 0.05–0.1 mol. free H_2SO_4 per l., at about 15°, and with c. d. of 8–15 amp. sq. dm. These conditions gave deposits contg. Fe 60–70, Cr 30–45 and O 1–5%. The current efficiency became somewhat greater when a combination of magnetite and iron anodes was used than when magnetite anodes alone were used. This plating soln. has low current efficiency (max. value shown, 24%, most values given on the graphs being below 14%), and very small throwing power.

EDWARD B. SANDELL

The electromotive activation of oxygen. ARTHUR B. LAMB AND LUCIUS W. ELDER, JR. *J. Am. Chem. Soc.* **23**, 137–63(1931).—In an effort to improve the activation of O at inert electrodes by means of catalysts dissolved in the bulk of the electrolyte, the velocity of oxidation of $FeSO_4$ solns. by gaseous oxidation was studied from the standpoint of rate of stirring, concn. of the O, concn. of H_2SO_4, concn. of the $FeSO_4$, concn. of neutral salts and effect of $CuSO_4$ coconut charcoal, Pt black and SiO_2 gel. Cu ions, coconut charcoal and Pt black have pronounced accelerating effects as does a decrease in the concn. of the H_2SO_4 below 0.1 *M*. H_2SO_4 solns. after exposure to the charcoal were able to liberate I_2 from KI, thereby proving the presence of peroxide in the charcoal and indicating that the accelerating effect of the catalyst is due to its ability to form a specific peroxide. A direct measurement of the depolarizing activity of the ferrous sulfate solns. contg. the charcoal catalyst showed that O_2 electrodes thus prepd. exhibited, at higher c. d., a higher working potential, a higher energy output and a much lower polarization than any previously studied.

MALCOLM DOLE

The effect of pressures up to 16,000 atmospheres upon the electromotive force of the Weston standard cell. THOMAS C. POULTER, CARTER RICHEY, ROBERT WILSON AND JOHN FULTON. *Proc. Iowa Acad. Sci.* **36**, 304(1929).—Weston standard cells of a variety of types were constructed and the e. m. f. was found to increase with the pressure

The shape of the curve was effected somewhat by the material of which the cell case was constructed. W. G. GAESSLER

Investigations on the electrochemical preparation of zinc and lanthanum persulfates. VICENTA ARNAL. *Helv. Chim. Acta* **13**, 1254–7(1930).—Attempts at direct prepn. of these compds. were unsuccessful. J. H. MOORE

The electrolytic production of dicalcium phosphate from apatite in India. SURENDRALAL DAS. *J. Soc. Chem. Ind.* **49**, 490–2T(1930).—Indian apatites generally contain only 15–20% P_2O_5, which limits their use in *fertilizer manuf.* to $CaHPO_4$ production by the electrolytic process. This process is used because the presence of deleterious substances leads to the waste of H_2SO_4, which is neither cheap nor abundant in India. The solv. of apatite in $HClO_4$ and other working details of the electrolytic process are noted. C anodes and Pt foil cathodes were used. A 40% soln. of $NaClO_4$ gave satisfactory results. $CaHPO_4$ is applicable to more soils than superphosphate, and the H_2 produced at the cathode can be utilized in subsidiary industries. W. H. BOYNTON

Characteristics of secondary batteries under high pressure. II. Variation of capacity of pasted-type storage battery under high pressure. SAKAE MAKIO. *Trans. Electrochem. Soc.* **59**, (preprint) 8 pp.(1931); cf. *C. A.* **24**, 1299.—A Pb storage battery was charged at 1 atm. (normal) and then discharged at various rates at a pressure of 80 atm. The capacity at 80 atm. is as much as 47% above that at normal. However, the increase in capacity is not permanent. Upon reducing the pressure to 1 atm., the capacity rapidly drops to normal. In other words, the after-effect is very short-lived, so on the whole there appears to be no practical advantage in operating batteries at high atm. pressures. Details of the high-pressure app. and a discussion of results are included. C. G. F.

Carbon tubes offer advantages in Cottrell units. A. D. CAMP. *Chem. Met. Eng.* **37**, 636–7(1931).—C is susceptible to attack only by O_2 at temps. exceeding 315°, by oxidizing agents such as HNO_3, and by CO_2 and water vapor at comparatively high temps. C has high elec. cond.; it does not soften or melt; and it has an extremely low coeff. of thermal expansion. The method of suspending the C tubes in a H_2SO_4 plant is illustrated. There are now in operation in H_2SO_4 and H_3PO_4 plants 21 Cottrell units equipped with C pptn. tubes; 23 are working in connection with the recovery of HF in oil refineries and chem. plants. C precipitator tubes show no trace of deterioration after 4 yrs.' continuous service in contact with HF and H_3PO_4. W. H. B.

The industrial development of the electrical purification of gases. LÉVÊQUE. *Rev. gén. sci. et ind.* **27**, 513–21(1930); 7 illus.—L. refers to the application of the *Cottrell method* to the recovery of losses from *lampblack factories* and of metallic fumes from smelters, but deals especially with the *purification of blast-furnace gas* at Homécourt, details of which are given. J. H. MOORE

Developments in the electrical industry during 1930. JOHN LISTON. *Gen. Elec. Rev.* **34**, 1–9, 92(1931).—The review includes chapters on: Emmet mercury vapor process; photoelectric control; elec. welding; television; vacuum tubes; lightning arresters; industrial heating. C. G. F.

Electric battery. WESTON ELECTRICAL INSTRUMENT CORP. Brit. 335,452, Nov. 28, 1929. Various details are given of the manuf. of a standard cell of the Weston type which may have a glass container with electrodes of Cd amalgam, Hg and Pt, and an electrolyte of $CdSO_4$ soln.

Dry cells. SOC. ANON. LE CARBONE. Ger. 511,583, Dec. 2, 1924. The elements for dry batteries have a solid depolarizer such as MnO_2 surrounding the pos. electrode as a dry porous mass.

Forming pressed graphite and pyrolusite depolarizing elements for dry cells. JACOB SUNDHEIMER. Ger. 511,889, May 22, 1929.

Carbon caps for galvanic cells. GEBR. KLEINMANN. Ger. 511,952, Feb. 1, 1930.

Galvanic element. SOCIÉTÉ ANON. LE CARBONE. Ger. 512,889, July 3, 1925. Addn. to 388,237. The porous mass is protected against infiltration of liquid by a skin formed by colloids mixed with the electrolyte. Thus, arrow-root is mixed with the electrolyte NH_4Cl for this purpose.

Accumulators. TH. GOLDSCHMIDT A.-G. Ger. 512,480, Aug. 1, 1929. A filling material for accumulator plates consists of highly dispersed litharge mixed with vaporized Pb, or Pb compds. and gas, and condensed and pressed.

Accumulators. COMPAGNIE GÉNÉRALE D'ELECTRICITÉ. Fr. 690,923, Feb. 18, 1930. Jars for Pb accumulators are made of a thermoplastic material composed of animal or vegetable fibers agglomerated with S and contg. fillers if desired.

Accumulators. MEYER WILDERMAN. Fr. 691,434, Mar. 7, 1930. Arrangement of porous separators almost filling the spaces between the electrodes is described.

Accumulators. EDWARD W. SMITH. Fr. 691,806, Mar. 12, 1930. Separators for elec. accumulators are made by forming a layer of inert fibrous material such as glass wool, Na_2SiO_3 and siliceous powder such as infusorial earth, allowing the mass to set and harden and then treating it with H_2SO_4 to dissolve out Na_2SO_4 and leave a porous mass.

Dry electric rectifier. SÜDDEUTSCHE TELEFON-APPARATE-, KABEL- UND DRAHTWERKE A.-G. Ger. 512,817, Oct. 31, 1928. The plate electrodes are sepd. by a layer contg. about 5% alkali metal.

Electrolytic deposition of metals. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 692,044, Mar. 17, 1930. See Brit. 324,589 (*C. A.* **24**, 3715).

Electrodeposition of metals. METALLGESELLSCHAFT A.-G. Ger. 512,913, Nov. 8, 1927. The metallic cathodes are covered with non-conducting material to avoid deposition of metal.

Electrodeposition of chromium. OSKAR HAHN (to Chrome-Plate, Inc.). U. S. 1,789,523, Jan. 20. The electrolyte is prepd. by the action of H_2O_2 on a soln. which may contain chromic acid or its suitable compds.

Revolving-drum apparatus suitable for electroplating. EDGAR S. THOMSON U. S. 1,790,289, Jan. 27. Structural features.

Apparatus for electroplating wares. SIEMENS & HALSKE A.-G. Ger. 511,022, Sept. 23, 1928. Details of arrangement are given.

Apparatus for electroplating metal objects. MAJOR ENGINEERING CORP. Fr. *690,956, Feb. 28, 1930.*

Chromium plating. *ELECTRO-MÉTAUX.*

... petroleum, which removes the bubbles.

ating with chromium. E. V. HAYES-GRATZE. **Brit. 335,161, June 13.**

troplating with Cr with the use of anodes of Pb or Pb alloy, auxiliary cath-

odes are employed to prevent excessive deposits on certain portions of the articles being plated such as automobile radiator shells; and insulating shields may be used to deflect the ions and prevent accumulation of pockets of gas. Various details of app. and procedure are described.

Chroming bath for electroplating. WILHELM A. F. PFANHAUSER. Ger. 505,864, Aug. 20, 1926. Details of construction.

Stripping chromium-plated articles. TERNSTEDT MANUFACTURING CO. Ger. 511,416, Feb. 12, 1930. The articles are subjected to anodic treatment in an aq. soln. of an org. acid that is capable of reducing Cr in soln. from the sexavalent to the tervalent state. This treatment removes the Cr without rendering the base metal passive to a second deposit. A suitable bath contains 60–120 g. of oxalic acid per l., and may be used at a temp. of 25–30° and at a voltage of about 12. Cf. *C. A.* **25**, 882.

Electric condensers impregnated with chlorinated naphthalene or the like. GRIGSBY, GRUNOW CO. Brit. 335,330, Aug. 9, 1929. Various details of manuf. are described.

Electrolytic cell (condenser). ALEXANDER GEORGIEV (to Aerovox Wireless Corp.). U. S. 1,789,949, Jan. 20. Structural features.

Weaving diaphragms for electrolytic cells from wires and asbestos threads, etc. I. G. FARBENIND. A.-G. Brit. 335,151, March 22, 1929. Mech. features.

Electrolytic cell with bipolar electrodes. ELEKTRIZITÄTS-A.-G. VORM. SCHUCKERT & CO. and ANTON FISCHER. Ger. 513,290, Apr. 12, 1929.

Electrolyzer with bipolar graphite electrodes for making alkali hypochlorites. ORONZIO DE NORA. Ger. 514,171, Dec. 19, 1929.

Electrolytic cell for extracting metals from salt solutions. I. G. FARBENIND. A.-G. (Konrad Teufel, inventor). Ger. 513,188, Feb. 22, 1927.

Electrolytic cell for generating oxygen and hydrogen. A. E. KNOWLES. Brit. 334,901, July 6, 1929. Various details are described of a cell suitable for use with NaOH or KOH soln. as electrolyte.

Electrolytic cell for the production of hydrogen and oxygen. DE NORDISKE FABRIKER, DE-NO-FA, A/S and CARL F. HOLMBOE. Norw. 46,781, Aug. 12, 1929. Structural features.

Electrolytic production of hydrogen and oxygen. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 45,860, Dec. 3, 1928. A hollow electrode contains an electrically conducting filling material on which the gas formation chiefly takes place.

Apparatus for electrolysis. DE NORDISKE FABRIKER, DE-NO-FA, A/S and CARL F. HOLMBOE. Norw. 45,940, Jan. 7, 1929. Structural features.

Cutting cavities or apertures in metal bodies by electrolytic action. W. GUSSEFF. Brit. 335,003, July 24, 1929. Various details of app. and procedure are described in which there may be used as electrolyte a 3–8% HCl soln.

Electrolysis of fused halides. I. G. FARBENIND. A.-G. (Johannes Brode, Carl Wurster and Erich Büttengenbach, inventors). Ger. 514,125, Apr. 27, 1929. Anodes made of, or coated with, W are used at a temp. below red heat.

Eliminating the anode effect in fused electrolytes. DET NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI. Norw. 45,694, Oct. 15, 1928. A stirring app. is introduced through a hollow electrode.

Electrical treatment of liquid hydrocarbons, etc. RHENANIA-OSSAG MINERALÖLWERKE A.-G. Ger. 514,320, July 8, 1923. Liquid hydrocarbons are polymerized or converted into other compds. by treatment in an elec. condenser with a. c. of high tension and high frequency in the presence of an indifferent or reactive gas, *e. g.*, O. The condenser is provided with a dielectric of porcelain, hard paper, mica or the like, and the gas is preferably injected in a finely divided state into the liquid. Alcs. and fatty oils, etc., may be treated similarly; *e. g.*, the hydrogenation of oleic acid is described. App. is shown.

Fluorine. KARL FREDENHAGEN. Ger. 511,808, July 18, 1928. Thoroughly dried acid alkali fluoride (*e. g.*, KF.HF) is electrolyzed between a Cu cathode and graphite anode. The fluoride is fused and subjected to a dry air current to prevent the access of moisture from the atm. Cf. *C. A.* **24**, 3449.

Hydrogen peroxide. I. G. FARBENIND. A.-G. (Georg Pfleiderer, inventor). Ger. 514,172, June 21, 1929. In the electrolytic manuf. of H_2O_2 at atm. or raised pressure, the anolyte and the catholyte are separately renewed, either periodically or continuously. App. is shown. Cf. *C. A.* **24**, 2065.

Sodium perchlorate. I. G. FARBENIND. A.-G. (Udo Ehrhardt, inventor). Ger. 514,340, Oct. 30, 1929. In the manuf. of $NaClO_4$ by electrolyzing a soln. of $NaClO_3$, an electrolyte contg. at the beginning at least 800 g. of $NaClO_4$ per l. is used, and more

$NaClO_3$ is added during the process so that the concn. of $NaClO_3$ does not fall below 150 g. per l. until the $NaClO_4$ content is about 1000 g. per l. The electrolysis is then continued until the $NaClO_3$ is substantially exhausted. It is necessary to work at 40–50°. An example is given.

Furnace for the electrolytic production of aluminum. P. E. Fröland. Norw. 46,412, April 29, 1929. Structural features.

High-voltage arc furnace. Aktieselskapet Norsk Staal (Elektrisk-Gas Reduktion). Norw. 46,645, July 1, 1929. Structural features.

Rotary electric cylinder furnace. Aktieselskapet Norsk Staal (Elektrisk Gas-Reduktion). Norw. 45,331, Dec. 31, 1928. The furnace is built with two or more rotating sections and intermediary stationary sections carrying the arrangements for the elec. heating.

Electric furnace suitable for dental uses. Ewald Carl Glitzke. Ger. 511,238, Nov. 22, 1927. See Brit. 298,001 (C. A. 23, 2668).

Electric foundry furnace. Demag-Electrostahl G. m. b. H. Fr. 691,453, Mar. 7, 1930.

Electric furnace for fusing metals. Emil F. Russ. Fr. 691,638, Mar. 10, 1930.

Multiple-hearth electric smelting furnace. Siemens-Schuckertwerke A. G. (Hans Freiherr von Droste and Rudolf Grundmann, inventors). Ger. 511,052, June 29, 1929.

Charging electric smelting furnaces for iron and steel, etc. Demag A.-G. Ger. 503,010, June 18, 1927. The charge is packed in a crate or the like made of the same material as the charge. Cf. C. A. 23, 1067.

Electric reduction furnace. Ivar Hole. Norw. 47,081, Oct. 21, 1929. Deviation of the current to the upper parts of the charge is avoided by means of a mantle surrounding the electrode and insulated from the latter. The mantle is carried gas-tight through the vault of the furnace.

Muffles and heating elements for electric furnaces. Établissements Bikso. Fr. 692,298, Mar. 19, 1930.

Electrically heated industrial oven. Heraeus-Vacuumschmelze A.-G. and Wilhelm Rohn. Ger. 514,354, Dec. 29, 1925.

Electrically heated annealing oven. Siemens-Schuckertwerke A.-G. (Johann Schnepf, inventor). Ger. 514,235, July 1, 1928.

Electrically heated annealing oven. Akt.-Ges. Brown, Boveri & Cie. Ger. 514,353, Apr. 19, 1928.

Electric induction heater for low-temperature heating. T. E. Beaumont and J. N. Waring. Brit. 335,337, April 30, 1930. Structural and elec. features.

Electric induction furnaces. Associated Electrical Industries, Ltd. Fr. 691,598, Mar. 8, 1930.

Electric resistance furnace. Elektriske Industriovner A/S. Norw. 45,402, Aug. 13, 1928. Structural features regarding the arrangement of heating elements above the charge are described.

Electrical heating resistances. Elektro-Hriz- und Wärme- G. m. b. H. Ger. 481,796, Mar. 20, 1927. A mixt. of C and metal oxide is molded, pressed and heated. During the heating, the carbonate layer fuses with reduced metal. The oxides mentioned are ZrO_2, ThO_2, CaO and U_3O_8.

Electrical resistances. Elektroterm A.-G. Ger. 512,264, Jan. 23, 1930. Addn. to 481,796 (preceding abstr.). Graphitic acid is added to the mixt. of C and metal oxides described in 481,796 to prevent the formation of carbides when the resistance is heated.

Electrical resistance element for producing infra-red energy. Carroll H. Bowles (to Burdick Corp.). U. S. 1,789,301, Jan. 20. A resistance element such as a suitable wire is mounted on an insulator such as a grooved rod and then coated with a compn. formed of non-metallic heat-cond. material such as SiC powder and Na silicate or other suitable binder while in a semi-liquid state; it is placed in an oven to set and dry, and then cured by heating to a high temp.

Electric heating resistances. Elektroterm. A.-G. Ger. 510,068, Apr. 4, 1928. A dry mixt. of C and metal oxides is mixed with about 10% of dry tragacanth powder and then kneaded with about 20% of water. The gummy product is extruded to form threads or bands, which are twisted and dried before baking.

Electric heating elements. Heraeus-Vacuumschmelze A.-G. and Wilhelm Rohn. Ger. 511,097, Dec. 2, 1927. Elec. heating elements are manufd. from alloys contg. more than 85% of Cr, *e. g.*, Cr 85–95 and Mo or W 15–5%.

Electrical immersion heater. J. H. CROSSLEY and ASSOCIATED ELECTRICAL INDUSTRIES, LTD. Brit. 335,354, Sept. 3, 1929. Structural features.

Cooling and regulating the temperature conditions of reactions in connection with electrothermic reaction processes. AKTIESELSKAPET MALMINDUSTRI. Norw. 45,608, Oct. 1, 1928. Steam alone or together with water is used for the cooling; the temp. is regulated by regulating the pressure of the steam.

Burning of electrodes. DET NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI. Norw. 46,761, Aug. 5, 1929. Electrodes are burned during the operation of the elec. furnace by means of the heat developed in the electrode by the elec. current. The current is applied to the electrode through a number of contact sticks inserted in the electrode at different levels. The extension of the burning zone in the electrode is regulated by applying the current to contacts located in more or less unburned parts of the electrode.

Self-burning electrodes. DET NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI. Norw. 45,726, Oct. 22, 1928. Structural features.

Self-burning electrodes. DET NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI. Norw. 46,285, March 25, 1929. The electrode mass is filled in at the top of a stationary guiding mantle and passes continuously downward through the mantle as it burns to a solid self-supporting electrode. In order to avoid sticking of the material to the mantle a non-metallic coating is placed between the mass and the mantle; the coating is removed by burning or by mech. means before it reaches the elec. contacts. Cf. C. A. **24**, 2386.

Reenforcement for self-burning electrodes. DET NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI. Norw. 45,981, Jan. 14, 1929. For self-burning electrodes in Al furnaces the mantle around the electrode, which is usually made of sheet iron, cannot follow the electrode into the metal bath, as the Fe would contaminate the Al. The reenforcement is therefore made in 2 parts: (1) a mantle of Al which follows the electrode, and (2) a number of ribs of iron which are removed before they reach the melting zone. Other structural features are given.

Furnace electrodes. DET NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI. Ger. 513,226, Mar. 16, 1927. A method of making self-baking electrodes is described.

Electrode for electrometallurgical, particularly electrolytic, furnaces. AKTIESELSKABET NORSK ALUMINIUM COMPANY. Norw. 46,762, Aug. 5, 1929. Structural features.

Holder for furnace electrodes. DET NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI. Norw. 45,137, May 7, 1928.

Electrodes for electrolytic cells for development of gases such as oxygen and hydrogen from water. KARL ROTH (to I. G. Farbenind. A.-G.). U. S. 1,790,248–9, Jan. 27. Structural features.

Electrode curtain for electric gas cleaner, comprising interlocked wire rings. METALLGESELLSCHAFT A.-G. (Theodor Bantz, inventor). Ger. 511,207, Nov. 23, 1929.

Automatic device for cleaning the discharge electrodes of electric gas cleaners. SIEMENS-SCHUCKERTWERKE A.-G. (Erich Wolfsdorf, inventor). Ger. 513,413, Mar. 1, 1927.

Electrical gas purification plant. METALLGESELLSCHAFT A.-G. Ger. 511,643, Oct. 21, 1928. Details of cleaning the electrodes by an electromagnetic tapping device are given.

Apparatus for the electrical purification of gases. METALLGESELLSCHAFT A.-G. Fr. 691,772, Feb. 27, 1930.

Electric apparatus for thermal treatment of metal filaments and wires. FIRMA CHRISTIAN WANDEL. Ger. 511,327, June 22, 1927.

Cleaning metal surfaces. MAX WOMMER. Ger. 514,157, Feb. 3, 1927. Fe and other metals are electrolytically cleaned with the aid of an a. c. and a superimposed d. c. App. is shown.

Hardening water-glass cements. STETTINER CHAMOTTE-FABRIK A.-G. VORM. DIDIER. Ger. 513,425, Sept. 10, 1927. In hardening water-glass cements used for lining metallic vessels, a d. c. is passed through the cement, the vessel constituting the pos. pole. The current decomposes the water-glass, or renders it reactive to siliceous materials, which may be added to the cement to accelerate the hardening in known manner. A current of a few milliamps. per sq. dm. of metal surface is suitable, the hardening being complete after about 3 days. App. is shown.

Lampblack, acetylene and hydrogen. I. G. FARBENIND. A.-G. Fr. 690,869, Mar. 1, 1930. Lampblack, C_2H_2 and H are made by treating hydrocarbons such as CH_4

or mixts. contg. it in an elec. arc at temps. of 2500° or above, under any pressure and under such conditions that the vol. of gas passed per hr. through the arc, measured in cu. m., is to the power of the arc, measured in kilowatts, below about 0.6.

Electric system for exploring the subsoil for detection of minerals, etc. MINES DOMANIALES DE POTASSE D'ALSACE. Brit. 335,051, Feb. 21, 1929; and Brit. 338,093, April 8, 1929.

Mercury-vapor device for flickering light effects. BRITISH THOMSON-HOUSTON CO., LTD. and C. G. GARTON. Brit. 334,949, June 14, 1929. In a device for producing flickering light effects by boiling Hg in a sealed container, the latter is filled with an inert gas, preferably N, with 5–15% of H at atm. pressure and a small quantity of inert powder, such as iron dust, is added to reduce the tendency of Hg globules to adhere to the walls of the device.

Electric luminous tubes. PATENT-TREUHAND-GES. FÜR ELEK. GLÜHLAMPEN M. B. H. (Marcello Pirani and Georg Gaidies, inventors). Ger. 513,306, Aug. 30, 1929. Elec. luminous tubes having a filling of alkali metal vapor are made of borosilicate glass contg. less than 50% of SiO_2. Part of the SiO_2 may be replaced by oxides of rare earth metals, *e. g.*, La_2O_3. Constructional details are given.

Filaments for lamps. SOC. D'ÉTUDES SCIENTIFIQUES ET INDUSTRIELLES Fr. 692,420, June 14, 1929. Filaments for wireless lamps are made from colloids of alkali, alk. earth or other metals or oxides of rare earth metals in the colloidal state.

5—PHOTOGRAPHY

E. P. WIGHTMAN

Micelle theory of the latent photographic image. F. WEIGERT. *Z. wiss. Phot.* (Schaum Festschrift) 29, 191-201(1930).—Within a micelle consisting of Ag halide, water, gelatin and "Ursilber," and which may also contain Ag_2S and dye mols., exposure causes an energy increase. Such micelles with increased energy represent the latent image. Development is then an activation of the developer mols. by the collected energy. This is therefore a chem. intermicellar process. The special photographic effects are explainable partly by the photomicellar process, which can absorb a great number of quanta in the same particle, and by the optical structure of the micelles. The S-shaped course of the density curve is caused by the internal development of the Ag halide by strong exposure which forms metallic Ag while at the same time the energy available for the development decreases. A. P. H. TRIVELLI

Early use of light filters in practical photography. E. STENGER. *Z. wiss. Phot.* (Schaum Festschrift) 29, 43–7(1930).—In the early days of the Daguerre process blue glass was used to decrease the effect of light intensity on the eye. Yellow and red glass was employed to increase the latent image obtained by shorter exposures (Becquerel effect) and green glass for landscape photography by the collodion process. William Crookes tried to eliminate the action of ultra-violet light by using a soln. of quinine bisulfate as a filter. Later he tried to get the same effect by the use of yellow glass filters. A. P. H. TRIVELLI

Amyl acetate in sensitometry. R. KIESER. *Z. wiss. Phot.* (Schaum Festschrift) 29, 87–90(1930).—The possibilities of the Am acetate lamp in sensitometric work depend upon the purity of the com. Am acetate. This can be tested with an Abbe refractometer at 15°. A. P. H. TRIVELLI

Sensitometry with spectrum and color chart. H. ARENS AND J. EGGERT. *Z. wiss. Phot.* (Schaum Festschrift) 29, 239–61(1930).—The foundations of color sensitometry are formulated with the spectrum and a color chart. Simple spectrum pictures give only qual. comparisons between different photographic emulsions and not abs. sensitivity. To obtain this, it is necessary to know the energy distribution or the intensity distribution over the whole spectrum. Sensitometric investigations show that every photographic emulsion has a typical density distribution over the spectrum which is independent of the failure of the reciprocity law. The photographic reproduction of pigments is made with a color chart. The color charts generally used are criticized and it is shown that in order to obtain quant. data, special gray scales must be photographed at the same time. A. P. H. TRIVELLI

The sensitivity of photographic emulsions for x-rays in relation to grain size. J. EGGERT. *Z. Elektrochem.* 36, 750–3(1930).—With 6 different exptl. photographic emulsions of different grain size it is shown that the photographic action of x-rays is directly proportional to the projective area of the grains. In spite of the great differ-

ences between the photographic action of x-rays and light there is also a similarity in behavior against desensitizers and the temp. coeff. A. P. H. TRIVELLI

Relation between photographic reversal and the sensitivity of the silver halide grain. FRANK E. E. GERMANN AND D. K. SHEN. *J. Phys. Chem.* **35**, 93–9(1931); cf. *C. A.* **23**, 5122.—In order to test the conclusion that only the larger grains are supplied with sensitizing material, the grains were sepd. by repeated centrifuging into the extremes of size, and coated in single grain layers. Developability-exposure curves obtained from these for the large- and small-grained fractions coincided with that of the uncentrifuged emulsion, which indicates that the lack of developability of 83% of the grains cannot be due to depletion of sensitivity-promoting material during the early part of formation. It has been found that treatment of the grains of AgI with certain developers prior to exposure increases their max. developability from 17% to higher percentages, up to 100%, depending upon the time of bathing. This increase is not removable by washing. From expts. it is concluded that the role of a sensitizer appears to be that of preventing or delaying reversal. The insensitivity of AgI emulsions is probably due to the existence of a wide range of specks among the grains combined with the phenomenon of quick reversal. The nature of photoretrogression, which is very marked in AgI, is probably due to the same causes as reversal. E. P. WIGHTMAN

Colored development of silver halide emulsions. R. E. LIESEGANG. *Z. wiss. Phot.* (Schaum Festschrift) **29**, 23–5(1930).—Development of colored pictures built up of colloidal Ag from AgCl paper emulsions is discussed. Theoretically the behavior of ... crent papers is explained on the basis of the Ag structure. A. P. H. TRIVELLI

Determination of the resolving power of photographic layers by the contact method. H. SCHNTZING. *Z. wiss. Phot.* (Schaum Festschrift) **29**, 266–80(1930).—The relative resolving power of a photographic layer is detd. as the difference in mμ of the smallest width of an opaque wedge increasing in steps of 2%, printed by contact at optimal exposure between transparent lines of more than 0.01 mm. thickness. This method is discussed as being preferable to any other method. The resolving power is governed by the turbidity, contrast, sharpness, exposure, wave length of the light, thickness of the lines, distance between the lines, time of developmental effects and the shrinkage of gelatin. A. P. H. TRIVELLI

Correct tone reproduction of color in photography. K. JACOBSOHN. *Z. wiss Phot.* (Schaum Festschrift) **29**, 202–8(1930).—A color tablet is described with which it is possible to det. at once the correct tone reproduction of color by placing the color in a gray surrounding (like the neutral color circle of Matthäi) which, to the eye, has the same neutral reflection power as the tone of the color. A. P. H. TRIVELLI

Exposing ripening specks. LÜPPO-CRAMER. *Z. wiss. Phot.* (Schaum Festschrift) 29, 5–7(1930).—Expts. on the laying bare of ripening specks in AgCl emulsions by KI treatment are described. It was shown that such emulsions have more specks within the grains than ordinary negative emulsions, which is in agreement with the higher reducibility of AgCl and the fact that photochloride is more stable than the other photohalides A. P. H. TRIVELLI

The ripening process of silver bromide. "Ursilber" and lysidine as sensitizers. J. M. EDER. *Z. wiss. Phot.* (Schaum Festschrift) **29**, 20–2(1930).—As early as 1881 E. ... posed the theory of sensitivity increase by the formation of Ag nuclei ("Ursilber") through the slow reduction of Ag halide by gelatin. Weigert and Luhr, and Schmidt and Pretschner have substantiated this by quant. analysis. Lysidine, a new sensitizer, when added to an emulsion which is not ammoniacal, increases the sensitivity 2 or more times. This would seem to be an increase of sensitivity which is not due to the formation of a Ag compd. contg. S. A. P. H. TRIVELLI

New methods of analysis of photographic products and raw materials. VII. Detecting silver iodide and silver chloride in photographic materials. H. BAINES. *J. Soc. Chem. Ind.* **49**, 473–4T(1930); cf. *C. A.* **24**, 2069.—A *spot test for AgI* is described which depends on the characteristic color of TlI and its insoly. in cyanide soln. About 1 cc of 0.2 *M* KCN soln. is gently poured onto the product, and when the covered portion is completely fixed most of the soln. is transferred by pipet to a white porcelain slab or developing dish. One or 2 drops of 1% $TlNO_3$ soln. is added. If I is present a yellow ppt is formed, whereas bromide or chloride gives a white or pale cream ppt. almost invisible on the porcelain. The method readily indicates the presence of 0.5% AgI in an iodobromide emulsion. *Test for AgCl.*—0.1 *N* NH_4CNS soln. is applied thinly to a few cm^2 of the product by means of cotton wool. After 16 sec. the product is washed in running H_2O for 15 min., removed and blotted. A few drops of ferric alum soln. free from added acid is applied to the treated portion (a red coloration indicates incomplete washing), and a little solid NaCl is now added. In the original absence of AgCl

the crystals of NaCl are colored pale yellow because of the formation of $FeCl_3$, but if AgCl were originally present the blood-red color of $Fe(CNS)_3$ is produced. The method depends on the intermediate soly. of AgCNS between AgBr and AgCl. Double decompn. with formation of AgCNS takes place only if AgCl is present. After the washing out of sol. salts the addn. of excess chloride ions reverses the original double decompn., the sol. thiocyanates thus formed being converted into the highly colored Fe salt by the ferric alum. **VIII. Determination of residual nitrate in washed emulsions.** H. BAINES. *Ibid* 479–81T.—Most of the known methods were inadequate. A modification of the Winkler method (*Chem.-Ztg.* **23**, 454(1899); **25**, 586(1901)) by Haase (*C. A.* **20**, 2472), which depends upon the production of a yellow color by addn. of a soln. of brucine to solns. contg. 0.5 to 20 mg. HNO_3 per l., in the presence of H_2SO_4, was tried and gave consistent but low results in the presence of gelatin. The method finally adopted to overcome this was to det. the quantity of nitrate forced through a membrane from an emulsion into distd. H_2O by the passage of a definite current for a definite time. This quantity would be no criterion of the original concn. of nitrate in the emulsion because of the variable quantity of other ions, but the difficulty was overcome by partial electrodialysis in the presence of a relatively large excess of an anion other than nitrate and by comparison of the quantity of nitrate ion transmitted with that obtained by a similar electrodialysis with standard nitrate soln. under the same conditions. The anion added was SO_4^{--} in the form of H_2SO_4, which gave the addnl. advantage that the p_H of the emulsion was lowered below the isoelec. point of the gelatin which caused it to migrate to the cathode. The diffusion membrane used was collodion contg. 2.5% camphor. Its method of prepn. is described. E. P. WIGHTMAN

Veröffentlichungen des Wissenshaftlichen Zentral-Laboratoriums der Photographischen Abteilung—AGFA. Bd. I. Issued by I. G. FARBENINDUSTRIE AKT. GES. Leipzig: S. Hirzel. 155 pp. M. 10. Reviewed in *Ind. Eng. Chem.* **23**, 343(1931).

Photography. LOUIS WESTON. Ger. 511,874, July 6, 1928. Non-inflammable films are treated with dil. aq. NH_3 for 6 hrs. between 30° and 50° to prevent their shrinking or wrinkling during the developing process.

Photography. I. G. FARBENIND. A.-G. (Wilhelm Schneider, inventor). Ger. 512,613, Oct. 31, 1929. A halation-preventing layer for photographic plates and films contains fuchsone dyes with one or more COOH groups in the mol. Aurine dicarboxylic and monocarboxylic acids are mentioned in examples. Cf. *C. A.* **25**, 652.

Photography. KALLE & CO. A. G. (Hermann Neuroth and Ulrich Ostwald, inventors). Ger. 514,057, Oct. 31, 1929. Images in tanned gelatin or other colloid are prepd. by bringing the colloid and an aryl azide on to a suitable support, *e. g.*, glass or paper, and exposing. The product may be worked up by the usual chromate process, and the image may be colored by dusting on a pigment or by applying a greasy pigment. An example is given. Cf. *C. A.* **24**, 3187.

Photography. N. V. CHEMISCHE FABRIK L. VAN DER GRINTEN. Ger. 514,084, Feb. 25, 1927. Photographic layers are prepd. by bringing on to paper or other support an aromatic diazo compd. contg. a tertiary N atom in the *p*-position to the diazo group, and free from substituents capable of yielding an anhydride with the diazo group. The diazo compd. from *p*-aminodimethylaniline is suitable. Development is effected by

treatment with an azo dye component, and the layer may include a salt, *e. g.*, $BaCl_2$, that hinders bleeding of the dye so produced.

Color cinematography. A. BERNARDI and RAYCOL, LTD. Brit. 335,310, July 18, 1929. Details are described of a system in which 3 or more images are simultaneously made, each through a color filter; the images are subsequently projected, one or more without color filters and the others through color filters.

Color cinematography. I. G. FARBENIND. A.-G. Brit. 335,432, Nov. 12, 1928. A high-speed panchromatic emulsion is used which contains a mixt. of coarse and fine grains of AgBr, of which the highly sensitive coarse grains are chiefly affected during the camera exposure, while the less sensitive fine grains are affected during a second or reversal exposure, in forming pictures intended for additive synthesis.

Optical system for color cinematography. F. J. CHESHIRE. Brit. 335,038, Aug. 30, 1929.

Measuring change of color in photographic layers. OTTO REEB. Ger. 511,167, Jan. 10, 1930. The degree of darkening, due to liberation of Ag, is detd. by placing the layer between two stationary condenser plates and observing the change in the capacity of the condenser.

Apparatus for developing light-sensitive materials in photography. FIRMA HANS VON SIERN. Ger. 512,769, Dec. 13, 1927. The app. is designed for the use of liquids that evolve gas.

Photographic sensitive surfaces. F. BUYLE. Brit. 335,357, Sept. 9, 1929. For prepg. surfaces for producing copies having a "charcoal or pastel like" appearance, supports such as wood, earthenware, metal, paper or "tissue" are coated with adhesive material and sprinkled with finely powd. material such as sand, glass, china clay or chalk, and a sensitive emulsion having a "minimum" of binding material such as gelatin or starch is applied. Cf. *C. A.* **24**, 4475.

Photographic films, etc. KALLE & CO. A.-G. (Maximilian Paul Schmidt and Wilhelm Krieger, inventors). Ger. 470,731, Feb. 23, 1926. Photographic films and layers are prepd. from mixts. of alkyl cellulose solns. with light-sensitive materials.

Photographic prints. KALLE & CO. A.-G. Ger. 512,614, Mar. 31, 1929. Diazo prints are obtained by applying diazo compds. of haloaminoalkylarylamines to a suitable carrier layer, exposing to light and developing in a bath contg. azo components. Thus, a paper is treated with the $SnCl_4$ double salt of diazotized 4-amino-3-chloro-6-methyl-1-ethylaniline, tartaric acid, H_3BO_3 and thiourea. After exposure, the print is developed in a soln. contg. NaOH, Na_3PO_4, NaCl and phloroglucinol. The result is a dark brown to black print on a white ground.

Photographic chromate-colloid prints. C. ROEHRICH. Brit. 335,128, April 23, 1929. A chromate-colloid print is improved after exposure by moistening it with water and then exposing it again to uniform light, and, before the second exposure, moisture is removed which adheres to the parts hardened by the first exposure (as by use of alc. or ether, heating, or the action of drying rollers).

Reflex prints. I. G. FARBENIND. A.-G. (Konrad Hebbel, inventor). Ger. 511,280, Aug. 21, 1929. Addn. to 509,762. In producing reflex prints by the method of 509,762 (*C. A.* **25**, 652), the film is treated with a hardening bleaching out soln. prior to treatment with the oxidizing soln.

Photographic line print. ARTHUR R. BAKER and WALTER N. BAKER. U. S. 1,789,013, Jan. 20. A base material such as tracing cloth is coated with a collodion or lacquer compn. and deliniating work is placed on the basic coating by photographic exposure of a light-sensitive coating contg. a dichromate, the portions of the basic coating between the parts being made substantially bare and exposed to the atm., and there is applied to the deliniated work and basic coating a solvent for the latter, such as alc. and ether, and more or less of the resulting soln. is removed from the base between the parts of the work, to leave such portions of the base free for drawing or writing on them.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Boron hydrides and "triphenylborylsodium." FRANZ FALTIS. *Z. anorg. allgem. Chem.* 187, 369–78(1930).—The structure of the B hydrides is discussed on the same principles as those developed by Ephraim (cf. *C. A.* **23**, 785) and Hellriegel (cf. *C. A.* **24**, 2619). The compd. $B(C_6H_5)_2Na$ explains the radical formation from hexarylethanes and triarylhydrazines. The cause of the dissocn. is not excessive valency

but the tendency to the formation of $(Ar:)_3A$. The central atom A surrounded by 3 aryl or similar groups is able to combine with another electron. E. SCHOTTE

Structure principles of boron hydrides. EGON WIBERG. *Z. anorg. allgem. Chem.* **187**, 362–8(1930).—The hypothesis of Hellriegel (cf. *C. A.* **24**, 2649) is attacked and the argument is based on the theory developed by W. (cf. *C. A.* **23**, 2897). E. S.

Reduction of nitrates with ferrous hydroxide. C. SANDONNINI AND S. BEZZI. *Gazz. chim. ital.* **60**, 693–700(1930); cf. *C. A.* **24**, 3962.—A review of the literature shows a certain lack of agreement regarding the nature of the oxidation of $Fe(OH)_2$ by nitrates, particularly in the works of Baudisch and Welo (*C. A.* **19**, 3182, 3333) and of Carslev (*C. A.* **24**, 1048). In view of this, expts. were carried out in which aq. $NaNO_3$, NaOH and $FeSO_4$ were boiled in the absence of O: (1) in proportions corresponding to the reaction $8Fe(OH)_2 + NaNO_3 \longrightarrow 4Fe_2O_3 + NH_3 + NaOH + 6H_2O$ and (2) with twice the proportion of $NaNO_3$ in the above equation. The quantity of NH_3 evolved and the rate of its formation were detd. The results show that, whether or not there is an excess of $NaNO_3$, the latter is reduced to NH_3 more rapidly in neutral soln. than in alk soln. (up to 20% free alkali). The % reduction was calcd. for the oxidation of $Fe(OH)_2$. In strongly alk. solns., the formation of NH_3 corresponds to oxidation of $Fe(OH)_2$ and to the Fe^{++}/Fe of the Fe_3O_4. In neutral soln. the mass becomes black (Fe_3O_4), and from the quantity of NH_3 finally evolved, it was calcd. that the reaction stops when the Fe^{++}/Fe ratio reaches the value for Fe_3O_4, which therefore is not in turn oxidized. In alk. soln. with 3–20% free NaOH, reduction is greatly retarded, and under the same conditions as with the neutral solns.; the reduction was in no case over 20%, and, instead of a black product, the $Fe(OH)_2$ was oxidized to a greenish gray mass, and the Fe^{++}/Fe ratio was, under all conditions, greater than that corresponding to Fe_3O_4. In the more strongly alk. solns. the mass became black, and the NH_3 reached 130% that corresponding to the reaction: $12Fe(OH)_2 + NaNO_3 \longrightarrow 4Fe_3O_4 + NH_3 + 10H_2O + NaOH$ and in every case oxidation of $Fe(OH)_2$ proceeded further than that corresponding to the Fe^{++}/Fe ratio. When the product from a neutral reaction mixt. with Fe^{++}/Fe ratio corresponding to Fe_3O_4 was boiled for many hrs. more, no further NH_3 was evolved, but when NaOH was then added more NH_3 was evolved. This was tested with various concns. of NaOH, and the results show that in neutral soln. Fe_3O_4 is not oxidized further, but that in alk. medium it is oxidized at a rate which depends upon the concn. of NaOH. With 2–20% free NaOH, oxidation of Fe_3O_4 is very slow, but with higher NaOH contents it becomes rapid. In weakly alk. solns. the product never becomes black, even after prolonged boiling, indicating that, parallel with the diminished reactivity, the $Fe(OH)_2$ loses its capacity of combining with ferric compds. (cf. Mjamoto, *C. A.* **21**, 1744), because of a rapid and extensive agglomeration. In strongly alk solns. both $Fe(OH)_2$ and Fe_3O_4 become sol. (cf. *Compt. rend.* **109**, 266(1889); *Pogg. Ann* 43, 117). If the soly. of $Fe(OH)_2$ is a result of the formation of a compd. of the type described by Baudisch and Welo (*loc. cit.*), at least it cannot be confirmed in any way. The fact that Fe_3O_4 reduces nitrates in neutral soln. indicates that Fe_3O_4 itself (given the soly. of the $Fe(OH)_2$ and $Fe(OH)_3$ in hot aq. caustic alkalies) is in part decompd., and the resulting $Fe(OH)_2$ is capable of a subsequent reduction. C. C. DAVIS

Amphoteric hydroxides, their aqueous solutions and crystalline compounds. XI. Synthesis and decomposition of high molecular, inorganic compounds in solution, for example, of molybdate, polymolybdate and polymolybdenum acids. GERHART JANDER, KARL JAHR AND WILHELM HEUKESHOVEN. *Z. anorg. allgem. Chem.* 194, 383–428(1930); cf. *C. A.* **25**, 631.—By use of the method previously described (*C. A.* 23, 1810, 3639) the H^+ range was accurately detd. for all Mo acids, their mol. values were fixed and an explanation was given for the reaction whereby higher mol. forms are built up from the lower forms or decompd. into lower forms. The following alkali salts of different Mo acids crystg. from aq. solns. were studied: normal molybdates, dimolybdates, paramolybdates, trimolybdates, tetramolybdates, octomolybdates or acid metamolybdates, dekamolybdates and 16-molybdates. Diffusion coeffs., light absorption, conductometric titration and thermometric titration of these compds. are described in detail. A comparison is made with the results of Sand and Rosenheim (*C. A.* 1, 599; 7, 1452) on polymolybdates. M. MCMAHON

Reversibility of the reactions between sulfur dioxide and lime and between calcium sulfide and calcium sulfate. J. ZAWADZKI AND Z. SYRYCZYŃSKI. *Roczniki Chem* 10, 715–27(727–8 French)(1930).—The equil. in $CaS + 3CaSO_4 \rightleftharpoons 4CaO + 4SO_2 - 238.6$ Cal. (1) was studied from both directions. The equil. pressures of SO_2 were found identical in all cases although, according to the secondary reaction $CaS + 2SO_2 \rightleftharpoons CaSO_4 + S_2 - 58.9$ Cal. (2), the compn. of the solid phase of the system (1) was altered. The pressures of SO_2 in contact with CaO at the beginning of the satn. by passage of the

gas across a solid layer are a little smaller than those of the equil., whereas the pressures of the same gas at the beginning of the decompn. of CaS + $3CaSO_4$ exceed those of the final equil. The results seem to exclude the possibility of explaining these anomalies by admitting the formation of solid solns. and intermediate compds. The abbreviated Nernst equation was used for calcg. the thermic effects. The heat of reaction (1) was found to be 232.4 to —5.5 Cal., av. 234.1 Cal.; that of reaction (2), 61.1 —57.2 Cal.
J. KUČERA

Permanganate decomposition in alkaline media. R. H. FERGUSON, WM. LERCH AND J. E. DAY. *J. Am. Chem. Soc.* **53**, 126–37(1931).—$NaMnO_4$ and $KMnO_4$ are converted into manganates with a loss in O in the presence of their respective concd. hydroxides. The reaction is speeded up by increased OH-ion concn. and by rise in temp. No MnO_2 was observed as a reaction product. R. H. FERGUSON

Purification of disodium phosphate. M. LEMARCHANDS AND C. TRANCHAT. *Compt. rend.* **192**, 50–1(1931).—Na_2HPO_4, as prepd. commercially by the action of Na_2CO_3 on $Ca_3(PO_4)_2$, contains various impurities, the most important of which is Na_2SO_4. The removal of Na_2SO_4 is rather difficult, but L. and T. have shown that it can be accomplished by adding $BaHPO_4$ to the soln of the impure phosphate.
LOUISE KELLEY

A laboratory process for the preparation of sulfuryl chloride. JULIUS MEYER. *Z. angew. Chem.* **44**, 41–2(1931).—Danneel's process, *C. A.* **21**, 1235, for the combination of Cl_2 and SO_2 with activated C is simplified. A ball condenser with 6 balls loosely packed with glass wool and granular C was used as the catalyst chamber. To prevent mutual gas loss the charge of the top ball was moistened with 1 cc. of liquid sulfuryl chloride. The gases enter the reaction chamber through a H_2SO_4 wash bottle which serves also as a flow indicator. 150 g. of SO_2Cl_2 may be prepd. per hr. at a gas flow of 3–4 bubbles per sec. Quant. combination of the gases is obtained at temps. up to 20°. The raw product is very pure and requires only 1 fractionation. In contrast to the Danneel process, the advantages of the method lie in the simplified app., the use of a small quantity of activated C, and the lack of a need for low temp. A. S. S.

Studies on zinc and barium ferrites. JOSEPH GUILLISSEN AND PIERRE J. VAN RYSSELBERGHE. *Trans. Am. Electrochem. Soc.* **59**, (preprint) **1**, 11 pp.(1931).—The formation of Zn ferrite by the direct addn. of Zn and Fe oxides was studied at various temps. between 580° and 660°. During the first 2 or 3 hrs. of heating, the reaction obeys Tamman's log law on reactions between solid phases. An apparent equil. appears afterward. At 580° the reaction takes place extremely slowly. It is found by thermal analysis that there is no evidence for the formation of a compd. contg. more ZnO than corresponds to $ZnFe_2O_4$, at least not below 1070°. The soly. of Zn ferrite in *N* and 2 *N* H_2SO_4 is studied. A mixt. of 7.5% SO_2 in air, passed over Zn ferrite heated at 450°, decomposes it slowly and liberates the Zn as $ZnSO_4$. The formation of Ba ferrite resulting from the heating of a mixt. of $BaCO_3$ and Fe_2O_3 was studied at 720°. It also obeys Tamman's law. The apparent equil. toward which the reaction tends is destroyed when the mixt. is stirred and heated again at the same temp.; the reaction goes on according to Tamman's law, the velocity of reaction being, however, considerably smaller than the original velocity. The results are discussed and explained on the basis of diffusion. C. G. F.

Stannites of calcium, strontium and barium. SETSURO TAMARU AND HARUO SAKURAI. *Z. anorg. allgem. Chem.* **195**, 24–34(1931); cf. *C. A.* **24**, 774.—When SnO is heated in the presence of CaO a reduction in vapor pressure indicates formation of a compd. Mixts. of SnO and CaO were heated in N_2, ground and heated *in vacuo*. With 1 hr heating in N_2 less than 1% of SnO volatilized if CaO:SnO > 1:1. With lower ratios the amt. volatilized increases. When CaO:SnO = 1:1 5 excess SnO was always present; with a ratio of 1:1, CaO is in excess. By heating CaO and ZnO in adjacent dishes *in vacuo* at 900°, with frequent grinding of the CaO, conversion to CaO.SnO was almost complete. Heating CaO-SnO mixts. in N_2 and H_2O at 800° forms $2CaO.SnO_2$ with some $2SnO_2.SnO_2$. By use of a similar procedure, SrO.SnO and BaO.SnO were prepd. from $BaCO_3$ or $SrCO_3$ and SnO. Attempts to prep. stannites of Mg, Zn and similar oxides were not successful, and no lowering of the vapor pressure of SnO occurred.
FOSTER DEE SNELL

Thiostannites of calcium, barium and strontium. SETSURO TAMARU AND YASUO TANAKA. *Z. anorg. allgem. Chem.* **195**, 35–40(1931); cf. preceding abstr.—By heating CaO-SnS mixts. in various proportions at 800° and volatilizing excess SnS *in vacuo* SnS.2CaO is isolated. Similarly SnS.2BaO and SnS.2SrO were formed. With MgO and ZnO the vapor pressure of SnS is not lowered and no compd. formation occurs. The thiostannites are gray powders readily purified by volatilizing the excess SnS used

in forming them. The sp. gr. is SnS.2CaO = 3.683; SnS.2SrO = 3.880; SnS.2BaO = 4.464. They dissolve in water with some hydrolysis. FOSTER DEE SNELL

A borate of silver. A. P. ROLLET. *Compt. rend.* **191**, 488–90(1930).—$AgNO_3$ was added to mixts of H_3BO_3 and $Na_2B_4O_7$ of varying compn. When the compn. of the mixt. exceeds $5B_2O_3$ to $1Na_2O$, then the white silver borate which ppts. has the formula $2B_2O_3 \cdot Ag_2O \cdot 2H_2O$; this borate is slightly sol. in H_2O, but the soly. increases in the presence of H_3BO_3. E. G. VANDEN BOSCHE

Carbon monosulfide. A. KLEMENC. *Z. Elektrochem.* **36**, 722–6(1930).—When CS_2 vapors are conducted through the region of a silent elec. discharge no new kind of gaseous mol. results, but the CS_2 becomes activated. This activated form of CS_2 releases its energy on coming in contact with the glass walls and decomposes to CS + S. Under certain conditions this reaction takes place with almost explosive violence and with the emission of light. The activated form of CS_2 may be frozen out with liquid air and preserved for as long as 2 hrs. On raising the temp., however, the activated CS_2 decomposes with a characteristic flame. Polymerized CS is brown in color. W. C. P.

Reactions with liquid chlorine. JULIUS MEYER AND WILLI AULICH. *Z. anorg. Chem.* **44**, 21–3(1931).—Liquid Cl shows little action upon metals below its b. p. except on Se and Te. Water accelerates the reaction. At room temp., a sudden chlorination takes place with V with evolution of heat. Au and Ag are readily chlorinated at 80° in the presence of water. Pt is hardly attacked at 100°. The tri- and di-chlorides are formed with Mn, V and Pb. MARY E. LEAS

Ceric selenate. JULIUS MEYER AND FRANZISKA SCHULZ. *Z. anorg. allgem. Chem.* **195**, 127–8(1931).—By crystn. from 50% H_2SeO_4, anhyd. $Ce(SeO_4)_2$ is obtained. This hydrolyzes with H_2O and is reduced by H_2O_2 to a sol. cerous salt. Because of the insoly. of $Ce(SeO_4)_2$ in dil. H_2SeO_4 double salts with alkali selenates could not be prepd. FOSTER DEE SNELL

Neodymium selenates (and sulfates). JULIUS MEYER AND CHARLOTTE KLEMANN. *Z. anorg. allgem. Chem.* **195**, 121–6(1931).—The following compds. were prepd. with approx. solubilities in g. per 100 g. H_2O at 0° as indicated: $Nd_2(SeO_4)_3 \cdot 5H_2O$ 4, $Nd_2(SeO_4)_3 \cdot 8H_2O$ 30; $KNd(SO_4)_2 \cdot H_2O$ 1.7; $RbNd(SO_4)_2 \cdot 2H_2O$ 1.3; $RbNd(SO_4)_2$ 1.2, $KNd(SeO_4)_2 \cdot 4H_2O$ 15; $RbNd(SeO_4)_2 \cdot 4H_2O$ 12.5; $NaNd(SeO_4)_2 \cdot 2H_2O$ 7. F. D. S.

Catalytic formation of hydrocyanic acid. II. Formation of hydrocyanic acid from hydrocarbons and ammonia. G. BREDIG, E. ELÖD AND ERNST DEMMLER. *Z. Elektrochem.* **36**, 991–1003(1930); cf. *C. A.* **21**, 3254.—The action of NH_3 on C_2H_2, C_2H_2 and CH_4 in the presence of catalysts was investigated. At temps. above 700° HCN formed, the yield rising through a max. with increasing temp. Under given conditions the HCN yield is highest with C_2H_4. The reaction between NH_3 and C_2H_4 is a catalytic surface reaction, catalyzed preferably by a mixt. of quartz and clay or by pure clay. The highest yields of HCN, based on NH_3 used, were from the proportions $NH_3 : C_2H_4$ = 1:1. The action of NH_3 on C_2H_4 or CH_4 is not direct, but by disproportionation of the hydrocarbon, *e. g.*, $C_2H_4 \longrightarrow 2C + 2H_2$, $2C_2H_4 \longrightarrow 2C + 2CH_4$, both reactions can be influenced by H or CH_4 addn. The relation of H formed to CH_4 formed depends upon temp., but at the test temp. of 800° it is quite independent of gas velocity. In the action of NH_3 on C_2H_2 the HCN yield is independent of duration of contact within the limits investigated. CH_4 forms HCN only at temps. at which the thermodynamic conditions for C_2H_2 formation are present. It is probable that HCN formation from C_2H_4 and NH_3 or CH_4 and NH_3 proceeds via intermediate formation of C_2H_2. III. **Formation of hydrocyanic acid from carbon monoxide and ammonia.** G. BREDIG, E. ELÖD AND RUDOLF MÜLLER. *Ibid* 1003–7.—The reaction between NH_3 and CO was investigated at 500°, 600° and 700°. The catalysts used were oxides of Al, Th and Ce the first without support and on broken stoneware, the second in admixt. with Al_2O_3 without support, the latter with and without support. The best HCN yields were with Al_2O_3 without support and with Ce oxide on stoneware support. SiO_2 gel and admixts. with Al_2O_3 and ThO_2 were unsatisfactory. With Ce oxide on stoneware the HCN yields, based on NH_3 used, increase with temp. rise and CO excess, but diminish on increase in velocity. With a 20-fold excess of CO and velocity of 12 l. per hr., or duration of contact 0.1 min., at 700° about 65% of the NH_3 is converted into HCN, with simultaneous NH_3 loss of 14% due to dissocn. With a 10-fold excess of CO the max. yield at 700° was about 48%; with 5-fold about 34%. Dissocn. of NH_3 is about 25–20% of the HCN yield; at 500°, 2–6%; at 600°, 5–12%; at 700°, 7–18%. From analyses of the final gases no conclusions can be drawn as to NH_3 dissocn. The reactions $NH_3 + CO = HCN + H_2O$, and $H_2O + CO = H_2 + CO_2$ take place together. IV. **Formation of hydrocyanic acid from carbon monoxide and ammonia.** G. BREDIG, E. ELÖD AND G. KORTÜM. *Ibid* 1007–23.—Increasing the excess of CO favors HCN

formation more than increasing the amount of NH_3. Addn. of N_2 causes merely a slowing down of the reaction. H_2 and CO_2 affect unfavorably the apparent equil. of HCN formation, CO_2 more so than H_2. Addn. of H_2 reduces decompn. of NH_3 into its elements. Moisture hinders HCN formation, not by displacing the equil. but by a secondary sapon. of HCN. The most probable main reactions are $2CO + NH_3 = HCN + CO_2 + H_2$, $CO_2 + H_2 = CO + H_2O$, with the following partial reactions: $2CO = C + CO_2$, $C + NH_3 = HCN + H_2$. C does not sep. in solid form, else it would coat the catalyst. The reaction $HCN + H_2O$ was investigated, but no definite conclusions were reached. Tests were made for intermediate formation of $HCONH_2$, but this was unstable at the temp. used. **V. Cerium oxide as catalyst in the formation of hydrocyanic acid.** G. Bredig, E. Elöd and Walter König. *Ibid* **37**, 2–11(1931).—The formation of appreciable quantities of Ce nitride, Ce hydride or Ce carbide as intermediate products of reaction gas and catalyst during catalysis of HCN from $CO + NH_3$ does not come into consideration. NH_3 formation by the action of N_2 and H_2 upon metallic Ce is complete only in the presence of O_2 and with simultaneous oxidation of Ce to CeO_2. It was detd. by x-rays that CeO_2 during catalysis suffered neither change of crystal structure nor lattice arrangement. Apparently the formation of HCN from CO + NH_3 takes place *via* nascent, free C. On this basis, the course of the reaction is shown. Under the conditions, no NH_4CNO is formed as intermediate product in the formation of HCN. There is apparently a relation between crystal size, adsorption power and catalytic activity of ceric oxides of the same properties, which have undergone various preliminary treatments. E. M. Symmes

Chemical reaction of formalin on potassium ferrocyanide. III. Everitt's salt. Takashi Kirigakubo. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 513–5(1930).—A greenish white ppt. is formed by the reaction of $K_4Fe(CN)_6$ soln. and HCHO (*J. Soc. Chem. Ind., Japan* **32**, 1123; Suppl. binding 357–9(1929)), having properties similar to Everitt's salt produced in the prepn. of HCN. Analysis showed that the 2 salts are identical. Literature on crystallography of the salt is scant. The greenish white ppt. obtained as above is much more nearly pure than Everitt's salt, which contains a minute quantity of granules. The relation between the rhombohedral crystal and the minute grains is not yet known, but they are perhaps isomers. Pure Everitt's salt is greenish white and stable in the air. HCHO acts on $K_4Fe(CN)_6$ soln. as a weak acid. E. M. S.

A contribution on the study of the chlorides of antimony. L. I. Saviuc. *Bull. soc. chim. Romania* **12**, 36–43(1930).—A discussion of the antimony compds. of higher order with bivalent and tervalent metals. Properties are given and formulas discussed of various salts, such as, $SbCl_5C_6H_5N.HCl$, $SbCl_5C_9H_7N.HCl$; $SbCl_6K.H_2O$; $SbCl_7Mg.9H_2O$; $SbCl_8Cr.10H_2O$; $SbCl_6Na.3H_2O.NaCl$; $2SbCl_6Cu.3H_2O.SbCl_6H.5H_2O$; $(SbCl_5)_2Cd.12CdCl_2.2H_2O$. These and more complex salts were analyzed and formulas based on the analyses are compared with theoretical formulas. Alice W. Epperson

Some combinations of cobalt and nickel salts with 2,3-diaminobutane. J. Frejka and (Miss) L. Zahlova. *Collection Czechoslov. Chem. Comm.* **2**, No. 10, 639–51(1930) (in French).—The authors have prepared derivs. of Co and Ni and diaminobutane containing the SO_4, Cl, Br, I, NO_3, CN and CNS radicals. The diaminobutane for the expt. was obtained by the authors' method of the catalytic reduction of dimethylglyoxime (*C. A.* **23**, 3662). It has been established that the behavior of 2,3-diaminobutane with respect to the salts of Co and Ni is similar to that of ethylenediamine and propylenediamine. In the prepn. of the sulfates, which previous authors have used as the starting points for other compds., certain difficulties were encountered since, by the action of $NiSO_4$ and diaminobutane (= bn)—even in the presence of excess of the ammonium—only the sulfate $[Nibn_3.2H_2O]SO_4.2H_2O$ was obtained, whereas other Ni salts under the same conditions gave only salts of the type $[Nibn_3]A.xH_2O$ and never salts of the type $[Nibn_2(H_2O)_2]A_2.H_2O$. The Ni salts reported are (s = sol., vs = very sol., ss = slightly sol., in H_2O): $[Nibn_2.2H_2O]SO_4.2H_2O$, fine, blue-violet crystals, ss; $[Nibn_3]Cl_2.H_2O$, red-violet crystals, vs, $[Nibn_3]Br_2.H_2O$, red-violet crystals, s, less than Cl compd.; $[Nibn_3]I_2.4H_2O$, red-violet needles, ss; $[Nibn_3](NO_3)_2.H_2O$, red-violet crystals, vs; $[Nibn_3](CNS)_2.H_2O$, violet needles, ss; $[Nibn_3](CNS)_2.H_2O$, violet needles, soly. not given, and $[Nibn_3][Ni(CN)_4]$, rose crystals, ss. The Co salts reported are: $[Cobn_3]Br_3$, small orange-red crystals, soly not given; the corresponding Cl compd. did not crystallize; $[Cobn_3]I_3.2H_2O$, yellow-brown powder, vs, and $[Cobn_3](CNS)_3.6H_2O$, orange-yellow powder, ss cold, s hot water. Details of the prepn. and analyses of these compds. are given.

Edward B. Sanigar

Stannic acid esters and stannic acids. P. A. Thiessen and O. Koerner. *Z. anorg. allgem. Chem.* **195**, 83–104(1931).—Ethyl stannate prepd. from $SnCl_4$ and EtONa

in abs. alc. was crystd. as $Sn(OEt)_4.2EtOH$ corresponding to a complex acid $H_2Sn(OEt)_6$. By very slow hydrolysis in abs. alc. soln. the ester is converted to a porous zinc hydroxide. The decompn. isotherms indicate the existence of the following hydrates: $2SnO_2.5H_2O$; $SnO_2.2H_2O$ (orthostannic acid); $4SnO_2.7H_2O$; $2SnO_2.3H_2O$ (pyrostannic acid, orthodistannic acid); $SnO_2.H_2O$ (metastannic acid) and $2SnO_2.H_2O$ (metadistannic acid) Of these only the last 2 are stable in a dry atm. The stable hydrates were isolated and x-ray interference bands recorded for them, for SnO_2 and for the freshly pptd. hydrate. FOSTER DEE SNELL

Action of boric acid on alkali chlorides and nitrates. L. HACKSPILL, A. P. ROLLET AND L. ANDRÈS. *Compt. rend.* 192, 48–50(1931); cf. *C. A.* 5, 3882.—When the chlorides of K, Cs, Rb and Li are heated at 100–150° with H_3BO_3 (I) in a current of steam, HCl is set free and the anhyd. pentaborate is formed in each case. With NaCl and an excess of I (50 mols. per mol. of NaCl), the removal of HCl ceases when 80% has been eliminated, indicating the formation of a chloroborate, $NaCl.(Na_2O.5B_2O_3)_2$. KNO_3 and $LiNO_3$, treated as above, give anhyd. pentaborates, but $NaNO_3$, even with a very large excess of I, gives the triborate, $Na_2O.3B_2O_3$. LOUISE KELLEY

Ammonium and potassium-dimagnesium acid carbonates. EDOUARD URBAIN. *Compt. rend.* 191, 1339–40(1930).—The reaction $MgCO_3 + KHCO_3 = MgKH(CO_3)_2$ was studied. The Mg carbonate is mixed in a little water charged with $MgCO_3$ in a current of CO_2 and variable quantities of $KHCO_3$ are added; the CO_2 current aids agitation. The end of the reaction occurs when the mother liquor rises clear above the cryst. material which should be cooled to 0° for the greatest yield. The compn. of the reaction product is upheld by analysis. This carbonate can also be prepd. by double decompn. of KCl and NH_4 dimagnesium acid carbonate. The NH_4-dimagnesium carbonate is prepd. in the same manner as the K-dimagnesium acid carbonate. A mixt. of isomorphous KCl and NH_4Cl gives a mixt. of the 2 carbonates with this method. M. MCMAHON

The stability of complex cobalt and chromium salts as solid phases. II. A. BENRATH AND H. STEINRATH. *Z. anorg. allgem. Chem.* 194, 351–7(1930).—In continuation of the investigation of the complex Cr amines (*C. A.* 23, 2899) a study was made of the reaction of these amines with HCl, HBr, HNO_3 and NH_3. The results are tabulated showing the stable phases; *e. g.*, the halogen pentamine compds. of Cr are stable toward NH_3 while the hexamine compds. change to the pentamine salts with HCl and HBr. III. A. BENRATH AND H. PITZLER. *Ibid* 358–68.—In continuation of the investigation of complex Co amines the system $(Co(NH_3)_5Cl)Cl_2 + 2HBr \rightleftharpoons (Co(NH_3)_5Cl)Br_2 + 2HCl$ was studied. The synthesis of complex Co nitrate amines in ammoniacal soln. and their decompn. in acid soln. indicated that only the hexamine salts are stable in synthesis while on decompg. the stable forms are the simple Co salts. The lower amines are metastable intermediate forms. M. MCMAHON

Studies on complex ions. III. The relative stabilities of the halogenoplatinates H. I. SCHLESINGER AND R. E. PALMATEER. *J. Am. Chem. Soc.* 52, 4316–31(1930); cf. *C. A.* 24, 2394.—For the reaction $PtBr_6^{--} + 6Cl^- \longrightarrow PtCl_6^{--} + 6Br^-$ to go 99% to completion the concn. of the chloride ion must be approx. 660 times that of the bromide ion. For the reaction between iodoplatinate and bromoplatinate ions there must be 25,000 times as much bromide as iodide ion, and completely to convert PtI_6^{--} to $PtCl_6^{--}$ there must be roughly 16,000,000 times as much chloride as iodide ion. A study of the absorption spectra of the various equil. mixts. indicates that in these reactions intermediate compds. are formed in soln. Solid intermediate compds. which have been reported in the literature are shown to be mixts. C. L. READ

7—ANALYTICAL CHEMISTRY

W. T. HALL

Nephelometric titrations. I. The equal-opalescence end-point. CLYDE R. JOHNSON. *J. Phys. Chem.* 35, 540–2(1931).—A possible source of error in the equal-opalescence end-point used in nephelometric at. wt. detns. is pointed out and work is to be undertaken to study the magnitude of such error. W. T. H.

Potentiometric precipitation titration of silver iodide. E. LANGE AND R. BERGER. *Z. Elektrochem.* **36**, 980–8(1930).—The expts. described show that $AgNO_3$ can be titrated potentiometrically with KI soln. with an accuracy of 0.003%. To obtain this accuracy, however, considerable attention was paid to the avoidance of possible errors. The titrating vessel was placed in a Cu vessel through which steam was passed to keep the temp. at 35° during most of the titration but raising it to 90° at the end. The calomel cell was connected with an electrolytic siphon tube contg. NH_4NO_3 soln. which, together with the calomel cell, was kept at 11° during the expt. by a bath of running water. The $AgNO_3$ and KI solns. were used from wt. burets and the KI soln. was kept in contact with N_2 gas. W. T. H.

Diphenylamine as indicator in the determination of iron in silicates. C. J. SCHOLLENBERGER. *J. Am. Chem. Soc.* **53**, 88–98(1931).—Fluoride (cf. Szebellédy, *C. A.* **24**, 4729) or phosphate increases the sensitivity of Ph_2NH as indicator in titrating Fe^{++} with $K_2Cr_2O_7$ by decreasing the Fe^{+++} concn. and so lowering its oxidation potential below the point at which the indicator shows color (cf. Kolthoff and Sarver, *C. A.* **25**, 48). In detg. FeO in silicates by Sarver's method (*C. A.* **21**, 2238), H_3BO_3 should not be added prior to titration with $K_2Cr_2O_7$, as Mn^{++} does not interfere and, by titrating in the crucible without delay, Fe^{++} is not oxidized by air. Org. matter may cause high results for FeO by "induced oxidation" (cf Kurtz and Lang, *C. A.* **23**, 4638). The Fe^{++} titration with $K_2Cr_2O_7$ and Ph_2NH may be followed by a $TiCl_3$ and KCNS titration for total Fe^{+++} after addn. of H_3BO_3. Procedures for the decompn. of silicates and the titrations are described. C. J. SCHOLLENBERGER

Determination of oxygen dissolved in sea water. MAURICE NICLOUX. *Bull. Inst. Oceanographique* No. **563**, 19 pp.(1930); cf. *C. A.* **24**, 4999.—The microdetn. of O_2 in sea water with 5–25 cc. samples and a special reaction tube is described in detail. During the expt. a ppt. of $Mn(OH)_3$ is formed which is treated with acid and KI and the liberated I_2 is titrated with $Na_2S_2O_3$. W. T. H.

Determination of sulfur in nickel. WILH. STAHL. *Metallbörse* **20**, 2613(1930).—Decompose 5 g. of finely divided metal in a covered beaker with aqua regia, heating until the metal is all dissolved. Transfer the soln. to a covered porcelain dish and add Na_2O_2 slowly. Evap. the soln. to dryness, add 20 drops of concd. HCl to the residue and 10 min. later 300 cc. of H_2O. Filter and det. SO_4^{--} in the filtrate in the usual manner. E. M. SYMMES

Technic of the determination of sodium. ERNEST KAHANE. *J. pharm. chim.* [8], **11**, 425–8(1930).—See *C. A.* **24**, 3457. S. WALDBOTT

New method for determining small concentrations of mercury vapor in air. B. L. MOLDAVSKII. *Zhur. Prikladnoi Khim.* **3**, 955–64(1930).—The method is based on absorption of Hg vapors from the air by gaseous Br_2 followed by absorption of the resulting $HgBr_2$ in water. V. KALICHEVSKY

New method to determine the content of mercury in air. KURT MÜLLER. *Z. Physik* 65, 739–58(1930); cf. *C. A.* **24**, 3727 —The absorption of light in air contg. various amts. of Hg was studied, a Hg-resonance lamp being used as the source of radiation and photoelec. cells to compensate fluctuations in the intensity of the Hg arc. With an absorption tube of 50 cm. length 3.9 to 1050 10^{-6} g. Hg per cu. m. can be detd. Observations were carried out in different labs., and compared with the results of chem. analysis (Stocks method). The latter gives much lower results than the phys. procedure which requires only 5 min. EGON BRETSCHER

New method for determining mercury in mercuric cyanide. E. CATTELAIN. *Bull. soc. chim.* **47**, 1406–7(1930); *J. pharm. chim.* [8], **12**, 529–31(1930).—C. recently detd. conditions most favorable for the reduction of mercuric salt to Hg_2Cl_2 by H_3PO_2 in the presence of H_2O_2 (cf. *C. A.* **24**, 5068) but with $Hg(CN)_2$ such treatment results in the formation of Hg. If, however, the cyanide is first oxidized by a satd. soln. of $KMnO_4$ in the presence of NH_4OH, the ppt. of Hg_2Cl_2 can be obtained. The excess $KMnO_4$ was reduced by heating the ammoniacal soln. with a little alc. and the ppt. of MnO_2 dissolved by HCl. W. T. H.

Content of iron soluble in hydrochloric acid in asbestos used with Gooch crucibles. E. CATTELAIN. *J. pharm. chim.* [8], **12**, 540–1; *Bull. soc. chim.* [4], **47**, 1404–6; *Ann. falsi.* **23**, 530–1(1930).—In 6 com. samples of white carded asbestos fibers to be used with Gooch crucibles, the Fe content varied from 1.187 to 8.553%; 2 gray samples had 5.369 and 12.783% and 4 samples of powd. asbestos from 0.067 to 5.179% Fe. Besides, traces of Mn were detected in all of a total of 14 samples. S. WALDBOTT

Determination of metallic iron in ores. W. ACKERMANN. *Chem.-Ztg.* **55**, 30–1 (1931).—Now that considerable quantities of Fe sponge are produced by the reduction of solid Fe ores at 700–1100°, the detn. of metallic Fe in the presence of oxides becomes

more and more important. The $HgCl_2$ method of Wilner-Merck was tested, therefore, with many synthetic mixts. As a rule the results were good but with ores contg. MnO_2, limonite, minette, and with mixts. contg. cementite, Fe_3P and FeS the results were unsatisfactory. The conclusion is drawn that in any given case it is necessary to try special tests to see whether anything is present that is likely to affect the results before relying upon the accuracy of the $HgCl_2$ method. W. T. H.

New method for the titrimetric determination of Caro's acid, persulfuric acid and hydrogen peroxide in the presence of one another. KARL GLEU. *Z. anorg. allgem. Chem.* **195**, 61-74(1931).—There are good methods known for the detn. of any one of these acids but no method previously described is infallible when H_2SO_5, H_2O_2 and $H_2S_2O_8$ are all present. Of these 3 acids, the oxidizing power diminishes in the order named. In dil. H_2SO_4 soln. at room temp., Caro's acid is reduced by an excess of HBr, liberating Br_2 for each mol. of H_2SO_5 present, and the reaction is complete before any appreciable quantity of H_2O_2 is reduced. If an excess of H_3AsO_3 is present, the liberated Br_2 oxidizes it to H_3AsO_4 and the excess can be titrated with $KBrO_3$. Then, if $MnSO_4$ is added, the H_2O_2 can be titrated with $KMnO_4$, the formation of a slightly yellow color (due to Br_2) being used as the end point. Finally, by adding an excess of H_3AsO_3, followed by H_2SO_4 and boiling 10 min., the $H_2S_2O_8$ is all reduced and the excess arsenite can be titrated with $KBrO_3$. The procedure is carried out as follows: The soln. of the 3 acids should, at the start, contain 10-20 milli-equiv. of H_2SO_4 in a vol. of 50 cc. Add a measured vol. of 0.1 *N* As_2O_3 soln. and 5 cc of *N* KBr. After 1-2 min. add 0.1 *N* $KBrO_3$ soln. dropwise from a buret until free Br_2 is present as shown by the yellow color. At once remove this with As_2O_3 soln. Continue titrating in this way until finally after 1 min. standing only a little Br_2 is developed which is removed with As_2O_3. From the vols. of As_2O_3 and of $KBrO_3$ used, compute the H_2SO_5 content. Now add 2 cc of 4 *N* $MnSO_4$ soln. and titrate with $KMnO_4$ until a slightly yellow color is obtained. This gives the H_2O_2 content. Finally add a measured excess of As_2O_3 soln. followed by 10 cc. of 18 *N* H_2SO_4; boil 10 min. and titrate back with $KBrO_3$ soln. Numerous test analyses of synthetic mixts. are given. W. T. H.

Determination of hygroscopic moisture of some mineral salts under production conditions. V. P. ZEMLYANITZIN. *J. Chem. Ind.* (Moscow) **6**, 1685-6(1929). Z describes the use of CaC_2 in detg. moisture. DAVID KAZ

Various observations on the analysis of sodium sulfate. A. NOEL. *Ind. verrieres* **1**, 123-4(1930).—Detn. of Fe by pptn. and titration and direct detn. of Na_2SO_4 are discussed. M. A. L.

New method for determining small quantities of water and carbonic acid in silicates. E. DITTLER AND H. HUEBER. *Z. anorg. allgem. Chem.* **195**, 41-59(1931).—The method consists in heating the substance in a Pt boat within a quartz tube in a stream of dry O_2 to 1200-1400°, leading the gases from the combustion tube into molten α naphthylene chlorophosphine, $C_{10}H_7POCl_2$, whereby 2 mols. of HCl are formed for every H_2O mol. evolved from the silicate. This HCl is carried by the O_2 stream into a measured vol. of NaOH soln. and, after the expt., the excess base is titrated against standard HCl with methyl orange as indicator. The tube contg. the phosphine deriv. is designed specially to ensure complete reaction between the H_2O and phosphine. Before starting the expt. the tube is heated in an oil bath, while a stream of dry O_2 is passed through it until no more HCl is evolved. A blank expt. showed that subsequent HCl evolved from the reagent amounted to only 3×10^{-5} g per hr., which need be considered only when the H_2O content of the silicate is low. When CO_2 is evolved, it is also absorbed by the base but can be detd. together with the HCl from the H_2O by a double indicator titration with methyl orange and phenolphthalein, or by using $Ba(OH)_2$ as absorbent and titrating first the excess $Ba(OH)_2$ and then adding excess acid, boiling off CO_2 and titrating the excess acid. The results obtained indicate that the method is good. W. T. H.

Detection and determination of small quantities of water in ethyl alcohol. F. SCHÜTZ AND W. KLAUDITZ. *Z. angew. Chem.* **44**, 42-4(1931).—Young's method of distg. with anhyd. benzene will serve to detect 0.1% H_2O in alc. by the formation of a ternary mixt. b. 64.5°. For practical purposes, however, the use of Dupré's test of adding CaC_2 and measuring the vol. of C_2H_2 evolved is more advantageous. But the following method of forming Cu acetylide with the C_2H_2, treating it with acid and Fe^{+++} salt and titrating the Fe^{++} formed is preferable. As app., a round-bottomed flask, connected with a condenser and the latter with an absorption flask, is shown with all connections of ground glass. The flask is dried carefully and weighed with and without the alc., 10-15% as much CaC_2 is added and the mixt. boiled 1.5-2 hrs. with reflux condensation. The evolved gas is passed through 50 cc. of $CuSO_4$ soln. which has been dild. with a little water. The resulting ppt. is filtered through a glass filtering crucible

the crucible and ppt. are placed in an acid soln. of Fe^{+++} salt and the titration is carried out with $KMnO_4$. The method is also applicable to detg. water in other liquids, *e. g.*, benzene and toluene. The results appear to be excellent. W. T. H.

Separation and determination of alkali chlorides, bromides and iodides in mixtures. Extension of the method to chlorates, bromates and iodates. COUSIN AND DUFOUR. *Trav. pharm. chim.* [8], **12**, 439–44(1930).—The detn. of Cl, Br and I in mixed aq. solns. of the alkali salts proceeds in 3 stages: (*a*) In a definite vol. of the mixt. det. the vol. of 0.1 *N* $AgNO_3$ soln. consumed in pptg. the total halogens as Ag salts by the Charpentier-Volhard method. (*b*) In another equal vol. of the mixt., set free the I by means of a nitrite soln. of *ferric ammonium alum*. Distil the I into a cooled aq. soln. of KI and det. I with 0.1 *N* $Na_2S_2O_3$. (*c*) In the well-cooled residual fluid from (*b*), liberate the Br by means of *PbO_2* in dil. AcOH soln., distil the Br into aq. KI soln. and titrate the I equiv. to Br with 0.1 *N* $Na_2S_2O_3$. PbO_2 in dil. AcOH soln. does not set free Cl from chlorides. To calc. the Cl present, subtract from the above total vol. of $AgNO_3$ soln. the sum of the two vols calcd. from the detd. quantities of I and Br. A quant. recovery of the halogen salts and their mixts. was made by this method. For quant. sepn. of chlorates, bromates and iodates reduce these first with Zn in neutral soln. by boiling on the water bath under reflux for 1 hr. A mixt. of bromates and iodates is also reduced with concd. HCl soln., excess of SO_2 must then be expelled by prolonged boiling, *i. e.*, for at least 30 min. S. WALDBOTT

Detection of fluorides using the zirconium lake of alizarin. IRWIN STONE. *J. Chem. Education* **8**, 347–9(1931).—To prep. the lake, mix a soln. of 0.5 g. alizarin in 200 cc. of alc with one of 1.5 g. $ZrCl_4$ in 75 cc. alc., filter and wash with alc. Suspend the moist ppt. in alc. to make 25 cc. and, as reagent, use 5 cc. of this suspension with 100 cc. of water. To 2.5 cc. of the soln. to be tested, add an equal vol. of concd. HCl and 0.5 cc. of the reagent. If the soln. contains more than 0.3 g. of F^-, the red color will turn to yellow almost immediately. Any oxidizing agent that liberates Cl_2 from HCl interferes by bleaching the reagent. As a rule it can be removed by a preliminary treatment with sulfite. In the detection of Al by the Atack-Yoe method, the presence of traces of F^- interferes with the test and large quantities make it useless. In fact the Atack-Yoe could be used in the above test for fluorides but is more sol. in HCl which is quite advantageous. W. T. H.

Stop-watch method for the determination of iodide in mixtures of halides. H. LEVY. *J. Soc. Chem. Ind.* **49**, 481–2T(1930).—The test depends upon the pseudo-catalysis by I^- of the oxidation of $S_2O_3^{--}$ by HNO_2. HNO_2 itself does not oxidize $S_2O_3^{--}$ but reacts with HI to give I_2 which in turn oxidizes $S_2O_3^{--}$ to $S_4O_6^{--}$. If the quantity of I^- is small, the second reaction takes place more rapidly than the first and the concn. of I_2 at any time is too small to give the starch test. If more than 1 mol. of HNO_2 is present for each mol. of $S_2O_3^{--}$, the complete oxidation of the latter is marked by the accumulation of I_2 in the soln. The speed of the oxidation of $S_2O_3^{--}$ by HNO_2 will depend on the quantity of I^- present. Directions for carrying out the test are given in detail. W. T. H.

Determination of iodide in the presence of bromide and chloride. FRIEDRICH L. HAHN. *Z. anorg. allgem. Chem.* **195**, 75–82(1931).—Iodide can be detd. potentiometrically in the presence of CCl_4 with the MnO_4^- reduced to Mn^{++} and the I^- oxidized to IO_3^-, or in the absence of CCl_4, to the formation of ICl with twice as much $KMnO_4$. If not more than 1 mol of I^- not more than 10 mols of Br^- are present, the first method is decidedly preferable but with larger quantities of Br^- it depends upon the properties of the potentiometer used which method will give the better results. The second end point can be detd. without the potentiometer if CCl_4 is present and the titration is continued until the soln. no longer shows the presence of any free I_2. W. T. H.

Spot test for nitrite. FRIEDRICH L. HAHN. *Mikrochemie* **3**, 31–3(1931).—Directions are given for prepg. pure α-naphthylamine oxalate and for cleaning, moistening and drying filter paper in such a way that a suitable test paper is obtained. When all the proper precautions are taken the test for nitrite is very sensitive. W. T. H.

Determination of the persulfate ion. A. KURTENACKER AND H. KUBINA. *Z. anal. Chem.* **83**, 14–36(1931).—No less than 169 expts. are described which were performed in testing the various methods that have been proposed for the detn. of $S_2O_8^{--}$. Exact results were obtained by the following procedure: Treat 45 cc. of 0.1 *N* $FeSO_4$ with 1 cc. of H_3PO_4, d. 1.7, add the persulfate soln., dil. to 100–200 cc. and titrate the excess with $KMnO_4$. W. T. H.

Colorimetric determination of cobalt in the presence of nickel. E. S. TOMULA. *Z. anal. Chem.* **83**, 6–14(1931); cf. *C. A.* **24**, 3727.—Take 40 cc. of the neutral soln. contg. Co on a 100 cc. measuring flask. Add 5 g. of NH_4CNS and 50 cc. of acetone,

Mix well and make up to the mark. Compare the color of the soln. (due to $(NH_4)_2[Co(CNS)_4]$) with that obtained with standard Co solns. treated similarly The standard soln. used in a diln. expt. should not be over twice as strong as the soln. analyzed or *vice versa*. When the concn. of Co is 8×10^{-3} mol. per l., a satisfactory test is obtained if no more Ni than Co is present. With more dil. solns. relatively more Ni can be present. In the test analyses the total Co content varied from 45.1 to 0.034 mg.
W. T. H.

Separation of lead from barium, strontium and calcium with ammonium acetate. J. MAJDEL. *Z. anal. Chem.* **83**, 36–45(1931); cf. *C. A.* **24**, 3194.—The conclusions drawn from the expts. described are as follows: When $PbSO_4$ is pptd. together with $BaSO_4$ some of the Pb is pptd. as $BaPb(SO_4)_2$ and this double salt does not dissolve, like $PbSO_4$, in NH_4OAc soln. and the error resulting is greater as the Ba content is increased With Sr a similar double salt is produced which is, however, sol. in NH_4OAc so that the Pb results may be as much as 20% too high if based on the assumption that only $PbSO_4$ dissolves. With a mixt. of $CaSO_4$ and $PbSO_4$ the results are better although not perfect with a single sepn.
W. T. H.

The evolution of elementary organic microanalysis. J. V. DUBSKÝ. *Chem. Weekblad* **28**, 46–52(1931).—See *C. A* **24**, 803.

Preparation of organic reagents in the analytical laboratory. III. Diacetyldioxime. K. H. SLOTTA AND K. R. JACOBI. *Z. anal. Chem.* **83**, 1–5(1931); cf *C. A* **24**, 2734.—Me Et ketone is converted into diacetylmonoxime by treatment with Et nitrite in ethereal soln. Then, without removing the monoxime, Na hydroxylaminedisulfonate is added; this gives the desired product. The last reagent is prepd from Na_2CO_3, SO_2 and $NaNO_2$. Directions are given in detail and a complete bibliography is appended.
W. T. H.

Microanalytical determination of carbon and hydrogen in organic mercury compounds. MAX FURTER. *Mikrochemie* **3**, 27–30(1931).—The results obtained by burning some org. compds. contg. C, H, Hg, S and N indicate that there are 2 difficulties to be overcome. (1) There is danger of some Hg distg over and being absorbed in the drying tube and (2) the PbO_2-asbestos filling of the combustion tube is likely to become poisoned so that it does not catalyze properly the combustion of C and H. The observation of Verdino (*C. A.* **22**, 3603) that Hg compds. can be burned without difficulty needs modification.
W. T. H.

Microdetermination of carbon and hydrogen by the method of Fritz Pregl. A. FRIEDRICH. *Mikrochemie* **3**, 20–6(1931).—Good results have been obtained in the microdetn. of C since pains have been taken to make sure that the O_2 used in the combustion is free from impurities. Sometimes the H results were unsatisfactory and the trouble was eventually traced to the moisture from the soda lime in the bubble counter It was found that passage of the gas through 50% KOH served to remove all CO_2 from the preheated gas and the soda lime was, therefore, omitted from the bubble counter and the results were then much better.
W. T. H.

Determination of hydrogen sulfide, methane and hydrocarbon vapors in the air. E. POZNER AND R. A. MELIKOVA. *Zhur. Prikladnoi Khim.* **3**, 965–77(1930).—H_2S is absorbed in NaOH soln., hydrocarbon vapors are adsorbed by activated charcoal (CH_4 is not affected), and methane is detd. by combustion.
V. KALICHEVSKY

A new color test for aromatic amines. I. DE PAOLINI. *Atti accad. sci. Torino* (Classe di sci. fis., mat. e nat.) **65**, 201–4(1930).—Benzoyl peroxide, in the presence of even traces of aromatic amines, produces a reddish brown to violet color. The test is carried out by adding the amine to an EtOH suspension of Bz_2O_2, and warming slightly. The test is general for all classes of aromatic amines and is probably due to the formation of quinones by oxidation.
A. W. CONTIERI

Bromo-iodometric investigations. I. Determination of urea, ammonium salts and formates. J. H. VAN DER MEULEN. *Chem. Weekblad* **27**, 550–2(1930); cf *A.* **24**, 5115.—To det. urea, take 25 cc. of a soln. contg. 35 to 40 mg., add 50 cc. H_2O, 10 cc. *N* $KHCO_3$ soln. and finally 10 cc. 0.5 *N* Br_2 soln. in 10% KBr. Stopper the flask and allow the soln. to stand for 30 min. Then add 10 cc. *N* KI and 15 cc. *N* HCl and titrate with $Na_2S_2O_3$. Titration of a blank soln. will give the cc. $Na_2S_2O_3$ equiv. to the urea. Instead of bicarbonate, borax can be used and is sometimes preferable. NH_4 salts and formates can be detd. in a similar way. **II. Determination of iodine in iodides.** *Ibid* 558–60.—To 25 cc. of soln. contg. about 0.1 g. I in a 250 cc. flask add 50 cc. H_2O, 10–15 cc. of Br-KBr soln., followed by 10 cc. *N* $KHCO_3$ soln. and 10 cc. urea soln. (10 g. urea per 1000 cc.). Heat the mixt. until all Br_2 has disappeared and then cool. Add KI

and HCl and titrate as above described. **III. Determination of the components of a mixture of iodates and bromates.** *Ibid* 578–9.—In the mixt. the bromate is decompd. with HBr. Then an excess of a carbonate or borate is added and also a reducing agent. In this way the bromate is destroyed and the iodate can be titrated. In a part of the original soln. the total iodate and bromate is detd. by the addn. of HI and titration of the I_2 liberated. **IV. Determination of components in a mixture of bromate, iodate and iodide.** *Ibid* 618–9.—The total amt. of bromate, iodate and iodide is detd. by addn. of excess Br water and consequent reduction of the excess Br. In a second portion iodate and bromate are detd. by addn. of HI. In a third portion iodate and iodide are detd after reduction of the bromate and addn. of enough excess Br water to convert the iodide into iodate. E. SCHOTTE

New method (gravimetric) for the determination of formaldehyde and of urotropine (hexamethylenetetramine). MIRCEA V. IONESCU AND CORNELIU BODEA. *Bull. soc. chim.* **47**, 1408–19(1931).—Ionescu (*C. A.* **22**, 3374) has called attention to the fact that menthone soln. is an excellent precipitant for HCHO and for urotropine and Verlander (*C. A.* **23**, 4646) has also described methods based upon this reaction. A series of expts. is described which were undertaken to det. the best conditions for carrying out the pptn. of the insol. product ($C_{17}H_{24}O_4$) which is formed with both urotropine and with HCHO. The soln. should be neutral and fairly dil., an excess of 5–10% menthone soln should be added and the mixt. allowed to stand 6 hrs. in the cold before filtering. Or, after adding the reagent, the soln. can be boiled for 10 min. and filtered when cold but long boiling causes decompn. The ppt. can be weighed after washing well with cold water and drying at 110–115°. Not more than 0.3 g. of urotropine should be present. If the soln. is acid at the start, it should be neutralized with Na_2CO_3 and then made barely acid with AcOH. Then use at least 3 times the amt. of menthone theoretically necessary and let stand twice as long. W. T. H.

A simple method for the detection of β-naphthol. G. DE HAAS. *Pharm. Weekblad* 68, 29–32(1931).—The green fluorescence obtained with AcOH and concd. H_2SO_4 distinguishes β-naphthol from α-naphthol, thymol and other phenols. The test is performed by adding to 1 cc. of the aq. β-naphthol soln. (1:1000), 5 cc. of glacial AcOH and a lower layer of 5 cc. of concd. H_2SO_4. A yellowish green zone forms at the interface of the 2 liquids and a green fluorescence develops on shaking. Thymol, cresols, phenol, guaiacol, creosote and α-naphthol give violet, brown or red colors but no fluorescence. The reaction is sensitive to concns. of 1:100,000, where the Millon and Br reactions are neg. It is useful for detecting β-naphthol in the presence of α-naphthol. The reaction evidently depends on the formation of a sulfonic acid. The fluorescent substance cannot be shaken out with Et_2O, petr. ether or $CHCl_3$. J. J. L. ZWIKKER. *Ibid* 63: The fluorescence is due to AcH present as impurity in the AcOH used by de Haas. With pure AcOH distd. over CrO_3 no trace of fluorescence is obtained, but an intense fluorescence occurs when a soln. of AcH is used in place of AcOH. A. W. D.

Determination of piperidine in a mixture with pyridine and its higher homologs. A. TRAVERS AND FRANQUIN. *Compt. rend.* **191**, 1340–3(1930).—Titration curves show that piperidine can be titrated electrometrically with the H_2 or quinhydrone electrode in the presence of pyridine, α-picoline, 2,4,6-collidine and α,α'-lutidine. W. T. H.

Some reactions of antipyrine and pyramidone. Detection of antipyrine in pyramidone. M. RIBÈRE. *J. pharm. chim.* [8], **12**, 444–7(1930); cf. *C. A.* **13**, 216; **20**, 1887. The following 4 reagents differentiate between antipyrine (*A*) and pyramidone (*B*): (*a*) CCl_3CO_2H (20%) and (*b*) $HClO_4$ produce only with *A* white ppts. sol. in excess of the reagent, or on heating. (*c*) *Ammoniacal* $AgNO_3$ is reduced at once by warming with *B*; *A* does not affect it. (*d*) *Acid* $HgNO_3$ *soln.* (*C*).—Dissolve Hg 2 g. in HNO_3 20 g.; after several days add 10 drops of a 5% soln. of $NaNO_2$. When 10 drops of *C* is added gradually to 2 cc. of a 1% soln. of *A*, a white turbidity appears and then a white ppt. is formed which becomes granular on shaking. Upon boiling, the ppt. disappears, but returns on cooling with brick-red color. Under the same conditions, *B* forms a violet color. For an approx. detn. of *A* in *B*, modify reagent *C* by adding an equal vol. of 20% CCl_3CO_2H (*D*). Add 10 drops of *D* to 2 cc. of a soln. of 0.10 g. of the *A*-*B* mixt. in 10 cc. H_2O. If *A* = 25%, the reactions are the same as for *A* alone, shading off for *A* = 15 and 10%. For *A* = 1%, the test is still pos. as follows: Carefully underlay with a pipet 2 cc. of the soln. with 1 cc. of *D*. A violet ring is seen (oxidation of *B*), and above it a white turbidity about 1 cm. high, indicating *A*. The limit of this test is at about 0.1% *A*. S. WALDBOTT

Titrating aldose sugars with standard iodine and alkali. G. M. KLINE AND S. F. ACREE. *Bur. Standards J. Research* **5**, 1063–84(1930); cf. *C. A.* **24**, 5670.—Expts. show that the customary procedure of adding a large excess of I and NaOH in the

titration of aldose sugars results in overoxidation and gives high values. A better utilization of the reagents is obtained by slow addns. of small portions of the reagents alternately to the sugar soln. Ketoses and non-reducing sugars are so slightly attacked that their presence does not interfere with routine detn. of aldoses in mixed samples. The method also provides an accurate means of standardizing the I against the NaOH soln. or *vice versa* by employing an excess of pure dextrose. In the procedure recommended, a sample which will react with approx. 20 cc. of 0.1 *N* iodine is dissolved and if necessary made neutral to phenolphthalein, 5 cc. of iodine is added from a buret, then 7.5 cc. 0.1 *N* NaOH dropwise. The process is repeated until 22 cc. of I soln. and 35 cc. of NaOH have been added, the whole requiring 5–6 min. After 2 min. the soln. is acidified with HCl and the liberated I titrated with 0.1 *N* $Na_2S_2O_3$. The excess of HCl may be titrated as a check. For best results, the excess I should require between 1.5 and 3 cc. of $Na_2S_2O_3$. R. C. HOCKETT

Hydrothermal origin of the Rand gold deposits. I. Testimony of the conglomerates. L. C. GRATON. *Econ. Geol.* **25**, Supplement to No. 3, 1–185(1930).—The Witwatersrand Au region of South Africa is the greatest metal mining district of the world, having in 45 yrs. produced more than half of the world's stock of Au accumulated during all time. It is the deepest mine in the world, 7640 ft. The origin of the deposits involves the future of the district. This paper summarizes the impressions favoring an epigenetic origin for the Au, rather than the placer hypothesis. Evidence is given as to the origin of the conglomerate reef, which leads to the conclusion that syngenetic accumulation of detrital Au with the reef gravels is so highly improbable and so unlike any of the detg. conditions under which Au placer deposits have been formed that the detrital hypothesis cannot be accepted. The evidence afforded by the conglomerates as possible and actual channel-ways has been considered and summarized and leads to the conclusion that the Au is and must be of hydrothermal introduction. ALICE W. EPPERSON

Beardmore-Nezah gold area, Ontario. GEO. B. LANGFORD. *Econ. Geol.* **25**, 251–69(1930).—The Au area lies 45 miles north of Lake Superior and east of Lake Nipigon. The general geology is given in detail. All consolidated rocks are of pre-Cambrian age, the basement member consisting of volcanics, plutonics and a minor quantity of sedimentary rock. The igneous rocks are all of basic types and are altered until they come under the general name of green-stones. Timiskaming Fe formations are the only ones held to be economic possibilities, although no com. ore bodies are developed. Au occurs in fissure veins of high-temp. origin. A bibliography is given. ALICE W. EPPERSON

Zoning in Michigan copper deposits. R. D. HOFFMAN. *Econ. Geol.* **25**, 285–6 (1930).—H. refers to Broderick's article (*C. A.* **23**, 4651) and emphasizes its value. The indication that Cu deposition may extend over a range of 20,000 ft. along the dip of the lode allows the geologist to measure one of the factors entering into the estn. of the

extension in the depth of a given ore body and opens up interesting exploration possibilities in the upper portions of the Keweenawan series. ALICE W. EPPERSON

The Sherrit-Gordon copper-zinc deposit. J. F. WRIGHT. *Econ. Geol.* **25**, 286–9 (1930); cf. Bruce, *C. A.* **23**, 4910.—W. presents evidence that the supposed syncline is more probably an overturned anticlinal fold. ALICE W. EPPERSON

Antimony and molybdenum deposits near Novotroïtsk on the Unde River, Transbaïkalia. A. A. SAUKOV. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, No. 13, 345–9.—Ore samples taken from these deposits analyzed 10–30% Sb_2S_3, hand-picked ones as high as 57.9% Sb_2S_3, with 0.52 g. Au per ton. Molybdenite deposits were found in the same district but were rather poor. S. L. MADORSKY

The Tin Mountain spodumene mine, Black Hills, S. D. G. M. SCHWARTZ. *Econ. Geol.* **25**, 275–85(1930).—The mine is located about 7 miles west of Custer, S. D., and closely resembles the Etta mine, which is the largest producer of Li minerals. The deposit is on the opposite side of the batholith from the Etta mine. The geology of the deposit is described, and the minerals observed are noted, those most abundant being microcline, quartz and spodumene. Tourmaline is very scarce. Pollucite is present and an analysis of it is given. The principal minerals of the 2 mines are the same, with the striking difference of an abundance of pollucite in the Tin Mt. mine. A. W. E.

Lignin and coal formation. ANTONIO PULT. *Atti III congresso naz. chim. pura applicata* **1930**, 529–32.—A review of various theories of the part played by lignin in coal formation. E. M. S.

Geology of southern Alberta and southwestern Saskatchewan. M. Y. WILLIAMS AND W. S. DYER. Can. Dept. Mines, Geol. Survey, *Memoir* **163**, 160 pp.(1930).—There are extensive coal mines and a very large untapped reserve of gas in the region. Enormous quantities of fine quality semi-refractory clays are also available.

C. H. LORIG

Occurrence of petroleum in North America. SIDNEY POWERS *Am. Inst. Mining Met. Eng., Tech. Pub.*, No. **377**, 46 pp.(1931). E. H.

Analyses of oil and gas from distillation of sediments. P. D. TRASK AND C. C. WU. *Econ. Geol.* **25**, 235–41(1930).—Preliminary results are given of an investigation on origin and environment of source sediments of Am. Petroleum Institute research program, its object being to study conditions under which sediments that may in future be source beds of petroleum are now accumulating. Analyses are given of oils from marine sediments, of the black ppt. which forms in the watery portion of the distillate, and of gases from sediments. The oils are similar and appear to be unsatd. and to contain S. The ppt. is high in Fe, H and C. The gases are so similar that it is thought impracticable to interpret the analyses of gas from sediments. Tables of analyses are given.

ALICE W. EPPERSON

Origin and environment of source sediments of petroleum deposits. J. D. HASSMAN. *Bull. Am. Assoc. Petroleum Geol.* **14**, 1465–8(1930).—A vast amt. of humic acids is formed in swampy regions where there is more sand than clay (*N. Y. Acad. Sci* 22, 1912, pp. 9–112; *Bull. Am. Assoc. Petroleum Geol.* **5**, 75–9(1921)). The origin of asphalt and hydrocarbons from humic acid in a Florida vandyke-brown lime has been shown. H considers that nature activates or energizes Si- and C-contg. materials so that they emit subatomic energy which produces chem. reactions at ordinary temps. and pressures by means of specific H ions. Evidence is offered that hydrocarbons are synthesized from humic acids by such emissions. ALDEN H. EMERY

Vanadium in carbonaceous minerals. JUN YOSHIMURA. *Bull. Inst. Phys. Chem. Research* (Tokyo) **9**, 878–81(Abstracts 84(in English) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, No. 271–3)(1930).—A peculiar-looking *semi-anthracite coal*, found in the prefecture of Fukui in a Jurassic deposit assocd. with sandstone, shale, liparite and clay, has been studied. It contains little water and gives a large quantity of ash. Detns. of the ash by Hillebrand's method gave a content of 0.01–0.03% V_2O_5—about the same as in the neighboring rocks. From these results it is concluded that the coal did not come from a vegetable source as usual but was partially carbonized through geological agencies. The ash of a coal from Heijo showed 0.091% V_2O_5. J. B. AUSTIN

Chemical composition and properties of Crimean keffekilite. I. D. KURBATOV AND V. A. KARGIN. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, No. 13, 321–4.—Samples of Crimean keffekilite were studied as to compn. and adsorptive properties. The material contains on the average about 50% SiO_2, 15% Al_2O_3 and over 20% H_2O. It cannot be used for purification of mineral oils but can be used, after preliminary activation, for purification of aq. acid solns. It adsorbs aniline dyes well from solns. S. L. M.

Experiments bearing on the biochemical reduction of sulfate waters. GEORGE

THIEL. *Econ. Geol.* **25**, 242–50(1930).—T. attempted to measure the role of bacteria as agents in biochem. reduction of meteoric sulfate solns. in carbonaceous sediments. In each of 7 types of sediments with varying amts. of org. matter, reduction was greater when microbian decompn. was undisturbed. There was some reduction in sterilized sediments, especially those high in $CaCO_3$. Conclusion: Too much emphasis has been placed on the importance of "dead org. matter" in ore genesis, especially as applied to carbonaceous sedimentary rocks. Expts. indicate that at the time of ore deposition org. matter was still being broken down by bacterial activity into its component parts, which by mutual interactions were capable of reducing sulfates. ALICE W. EPPERSON

Corrosion and regeneration of porphyry-quartz. G. G. LEMMLEIN. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, No. 13, 341–4.—Quartz crystals having irregular outlines are sometimes found. This irregularity is usually explained on the basis of corrosion by the magmatic melt just preceding solidification. A study of such corroded crystals was made. S. L. MADORSKY

Blast-furnace slags on Kola Peninsula and Novaya Zemlya Island. D. S. BELYANKIN. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, No. 10, 245–50.—Fragments picked up here proved on chem. and phys. examn. to be blast-furnace slags. The Novaya Zemlya fragment resembled the Cleveland, England, blast-furnace slag, and the Kola fragment resembled that of Lehigh Valley, Pennsylvania. The theory is advanced that fragments were carried from the respective countries to the White sea region by the Gulf Stream. S. L. MADORSKY

Patina on quartz as a time indicator. E. GEHRCKE. *Physik. Z.* **31**, 970–3(1930).—The patina on specimens of quartz and flint can serve for the detn. of geological age. A layer 0.3 mm. thick can be formed in 6 months at 20° by 10% NaOH but requires 50,000 years if the alkalinity is 0.7 mg. NH_3/l. FRANK URBAN

Colloid-chemical theory of salt lakes. S. A. SHCHUKAREV AND T. A. TOLMACHEVA. *J. Russ. Phys.-Chem. Soc.* **62**, 777–816(1930).—Kurnakov, and after him Krotov (*C. A.* **22**, 4424), regard the deposition of salts from seashore lakes as the result of ionic interchange, whereby first SO_4 ions (reaction between $MgSO_4$ and $CaCO_3$) and then Mg ions (reaction between $MgCl_2$ and $CaCO_3$) are removed from the soln. The above view fails to explain the accumulation of sulfates and carbonates in inland lakes, a phenomenon which can be accounted for on the basis of exchange adsorption by the silt colloids. The greater concn. of Na and Mg ions causes them to displace Ca ions from the clay and humus material of colloidal nature. Geological and climatic changes may transform the sea lake into an inland salt deposit; NaCl is subsequently leached out by the rain water, and the adsorption proceeds in the opposite direction, Ca ions being removed from soln. in exchange for Na as Na_2SO_4 and Na_2CO_3. The above theory, as applied to Lake Sakskoye (Crimea), was experimentally tested by studying the adsorbent properties of the lake silt. It was necessary, in order to remove the adsorbed metallic ions, to wash the silt with HCl, although such treatment resulted in the loss of $Fe(HS)_2$ and consequent change in adsorption power. The residue consisted of finely divided clay contg. 2% org. matter. It was suspended in water, and H-electrode titrations were made with $BaCl_2$, $CaCl_2$, $MgCl_2$, NaCl and LiCl solns. For bivalent ions, the adsorption order was Ba > Ca > Mg, for univalent, Na > Li. In solns. more dil. than 0.3 *N*, the adsorption conformed to Freundlich's isotherm. The adsorption capacity of the silt for H ion appeared to be greater than for Ba ion. The adsorption of Ag ion was followed with the aid of a Ag electrode. Suspensions of the silt were also titrated with NaOH and $Ba(OH)_2$ solns., the buffer action in the latter case being greater. Addn. of neutral salts also increases the buffer action, which thus depends on the adsorption of cations. The changes in the compn. of the water of salt lakes lying near the sea are caused by biochem. reduction of the sulfates and exchange adsorption. The latter process prevails when the sulfates disappear rapidly from soln. (as in the case of lakes which do not communicate with the open sea). B. SOYENKOFF

Uniform terminology and formulas for ore dressing. Ore dressing committee of the Gesellschaft deutscher Metallhütten und Bergleute e.V. *Metall u. Erz* **27**, 637–42 (1930).—In this comm. report a standardization of hearth terminology is recommended and a method for calcg. ore dressing efficiency is suggested. The relation of the practical degree of sepn. at any time to the max. degree of phys. sepn. is designated "*efficiency*," while by "*max. efficiency*" is understood the relation between the max. practical degree of sepn. and the max. theoretical degree of phys. sepn. An explanation by H. MADEL is included. H. STOERTZ

Dressing of iron pyrites and heavy spar at Meggen. GLATZEL. *Metall u. Erz* **27**, 642–54(1930); **28**, 7–14(1931).—A thorough discussion of the dressing of these ores, including also the geology of the deposits, chronological development of their treatment, equipment used, power requirements, efficiency, water consumption, waste water purification and cost. H. STOERTZ

Development of world copper economy in relation to progress in mining, ore dressing, and smelting technic. ERNST HENTZE. *Metall u. Erz* **28**, 1–7(1931).—Mine and smelter production as well as world consumption of Cu has increased about 100% since 1920. The technical progress of mining, ore dressing and smelting during this period has been such that the production has come more and more into the hands of a few large companies, and Cu therefore today costs relatively no more than before the war. Annual production and cost data are given for 20 large American producers. H. STOERTZ

Flotation fundamentals. I. Dept. Mining and Met. Research, Univ. of Utah, *Tech. Paper* 1(1928).—**The floatability of pure minerals and synthetic mixtures of pure minerals under standardized conditions.** A. M. GAUDIN, HARVEY GLOVER, M. S. HANSEN AND C. W. ORR. *Ibid* 3–5. **Galena.** A. M. GAUDIN. *Ibid* 6–30.—The effect on the floatability of galena of various collectors, depressing agents and toxic agents is

shown in an extensive series of graphs of recovery vs. amt. of reagent per ton. **Pyrite.** A. M. GAUDIN AND C. W. ORR. *Ibid* 31–49.—A similar series of graphs is given for pyrite. When K Et xanthate is used as a collector, pyrite is the most floatable of the sulfides of Fe, Pb and Zn. The amt. of collector required for complete recovery frequently would barely form a complete monomol. film on the mineral grains. Depression of pyrite can be produced by pptg. insol. compds. on the mineral surface. **Differential flotation of synthetic mixtures of galena and sphalerite, and galena and pyrite.** A. M. GAUDIN AND C. W. ORR. *Ibid* 50–55.—With mixts. of galena and sphalerite, both NaCN and $ZnSO_4$ are depressing agents for sphalerite; their joint effect is better than either singly. K chromate depresses galena, but fails to help to float sphalerite. $CuSO_4$ floats sphalerite but fails to depress galena. The use of $CuSO_4$ + K chromate gives the desired sepn. CaO or NaOH depressed both pyrite and galena. Cyanide depressed pyrite and floated galena. **Flotation of carbonate minerals by fatty acids as affected by soluble salts.** A. M. GAUDIN AND MAHLIN S. HANSEN. *Ibid* 56–77.—All carbonate minerals tried (calcite, magnesite, cerussite, siderite and rhodochrosite) were floated. Differential flotation of one from another may be possible by the use of suitably selected fatty acids as collecting agents. **Flotation of some oxide and silicate minerals.** A. M. GAUDIN AND HARVEY GLOVER. *Ibid* 78–101.—*Quartz* can be floated with oleic acid or Na oleate when a sufficient amt. of frothing agent is added to form elastic bubbles. The amt. of oleic acid is < the amt. to form a complete monomol. film. Pb and Cu salts greatly activate, while quadrivalent and tervalent salts inhibit, the flotation of quartz when Na oleate is used as a collector. Flotation of quartz is very sensitive to acidity; a slightly alk. circuit is best. Na silicate is the best depressing agent for quartz when Na oleate is used as a collector. *Cassiterite* can be floated with Na oleate and with satd. fatty acids provided a suitable frothing agent is used. *Hematite* can be floated with Na oleate and some of the satd. fatty acids when a suitable frothing agent is used. Cu and Pb salts decrease the recovery of hematite. *Feldspar* can be floated with Na oleate and satd. fatty acids provided a suitable frother is added. Although quartz is floated by these same reagents, feldspar floats first. Sol. salts affect feldspar similarly to quartz. II. **The floatability of pure minerals and synthetic mixtures of pure minerals under standardized conditions. Chalcocite.** A. M. GAUDIN AND PAUL M. SORENSEN. *Ibid* **4**, 25 pp.—The effect on the floatability of chalcocite of various collectors, depressing agents and toxic agents is shown in an exhaustive series of graphs. Anions that form insol. Cu salts inhibit the flotation of chalcocite. Complete depression is accomplished by the addn. of small quantities of thiosulfate, sulfite, sulfide, ferrocyanide or ferricyanide ions. III. **Floatability of pure minerals and synthetic mixtures of pure minerals under standardized conditions. The flotation of the carbonates of copper, malachite and azurite.** A. M. GAUDIN AND J. SHELDON MCLAUGHLIN. *Ibid* **5**, 37 pp.—Malachite and azurite can be floated from a siliceous gang by means of suitably selected satd. fatty acids and fatty acid soaps. These reagents will not effect a sepn. of Cu carbonates from a calcite gang because of the formation, by the Cu and Ca ions present, of identical surfaces on the 2 carbonates. Relatively large amts. of several N-contg. org. substances such as amines and hydrazines will float $CuCO_3$ from calcite. Org. N-S reagents, such as thiocarbamates, are more powerful. Xanthates and thiocarbamates have been shown to collect because of the formation of insol. Cu compds. on the surface of the $CuCO_3$. Org. hydrosulfides act similarly. **IV. Floatability of pure minerals and synthetic mixtures of pure minerals under standardized conditions. Sphalerite.** A. M. GAUDIN, C. B. HAYNES AND E. C. HAY. *Ibid* **7**, 40 pp.(1930).—Sphalerite is difficultly floatable. Heteropolar org. compds. whose hydrocarbon groups contain < 5 C atoms usually do not collect the mineral satisfactorily. H-ion concn. of the pulp is very important, several collectors requiring control of the p_H within very narrow limits. Surprisingly few collectors were found. The most powerful was diisoamylammonium diisoamyldithiocarbamate; others were the xanthates higher than hexyl, the thiocresols, thioalcohols, trithiocarbonates, certain amines and hydrazines. The mineral is very amenable to activation by salts of the metals whose sulfides are less sol. than ZnS; the most powerful are Ag, Cu, Hg and Pb salts. The sequence of potency of these various activators is not the same for all collectors, but depends on the insoly. of the salt formed by the anion of the collector with the cation of the activator, as well as the insoly. of the sulfide coating on the sphalerite. Cyanide is not a depressing agent for pure sphalerite, but it is most suitable to undo the activation brought about by Cu salts. **V. Floatability of pure minerals and synthetic mixtures of pure minerals under standardized conditions. Some attempts at reducing the cost of floating copper carbonate ores. A. M. GAUDIN AND ARVID E. ANDERSON.** *Ibid* **9**, 25 pp.(1930).—By the use of Pb salts,

particularly $Pb(NO_3)_2$, in connection with Am xanthate, the cost of floating $CuCO_3$ ores can be reduced about 1/3. $Zn(NO_3)_2$ and possibly other Zn salts have been found of value as activators under certain restricted conditions. No collector more effective than Am mercaptan has been discovered. The possibility of regenerating the reaction product from the collector that usually goes with the concentrate has been outlined. Some data pertaining to the flotation of malachite and of cerussite at various p_H values and with various added substances have been detd. A. H. E.

Progress in flotation and equipment. S. G. SWAINSON. *Eng. Mining J.* **131**, 69–71(1931).—Significant recent developments in flotation technology are noted in connection with Mn, phosphate rock, fluorspar, barytes and coal. On a lab. scale other non-metallic minerals have been floated such as: bauxite, mica, calcite, kaolinite and feldspar. Every plant in the Michigan Cu country has adopted flotation, and concentrates running 50–60% Cu are being produced from tailing of 0.30–0.60% Cu In Northern Rhodesia a new process under development reduces the Cu to the metallic state; it is then sepd. by flotation. Crushing machinery, fine grinding and classification, flotation machines, traction thickeners and filters are briefly discussed.
W. H. BOYNTON

Application of a reclassification method to the flotation process for the improvement of ore dressing results. H. BÖRNER. *Metall u Erz* **27**, 654–9(1930).—An investigation of metal distribution in the flotation process with the aid of sieve and uniformity analysis, as applied to Au ores, and the dependence of metal recovery upon the grain size of the flotation slime. Whether this reclassification process can be applied depends upon the value of the metal being recovered. H. STOERTZ

The effect of dissolved substances on gravity concentration. F. J. TROMP AND E. BEYERS. *J. Chem. Met. Mining Soc. S. Africa* **31**, 130–1(1930); cf. *C. A.* **24**, 3200, **25**, 268.—Discussion. ALDEN H. EMERY

A new concentrator at Rio Tinto. R. O. STOKES. *Can. Mining J.* **52**, 97–9 (1931).—This 2000-ton flotation plant treats disseminated Cu sulfides. The novel arrangement of classifiers and ball mill is noted. A general flowsheet of the concentrator and a flowsheet of the flotation section are shown. The pipe arrangement of ball mill and classifier is illustrated. Flow meters are of the restricted orifice type and work on the principle of the difference of pressure on each side of an orifice plate, which pressure is transferred to a Hg U-tube, one limb contg. a float. The provision of d. recorders on both the rougher and cleaner flotation circuits thus enables the operator to see at a glance what the diln. is at any moment and gives a clue to other changes which cannot be detected immediately. Also in *Mining Mag.* **43**, 329–36(1930)
W. H. BOYNTON

The Lake Shore mine. A. BRIAN. *Can. Mining J.* **52**, 89–92(1931).—An outline of the development of the mine and a description of some of its present equipment are given. Several illustrations are included. W. H. BOYNTON

Kowkash gold area. L. F. KINDLE. *Can Mining J.* **52**, 94(1931).—A preliminary rept. and recommendations for prospecting are given. W. H. BOYNTON

Central milling in the Tri-State district. ELMER ISERN. *Eng. Mining J* **131**, 49–54(1931).—The trend toward central milling is growing. The operations along these lines on the holdings of the Commerce Mining & Royalty Co. in the western part of the Kansas-Oklahoma section of the Tri-State Zn-Pb district are described. The flowsheet of the Bird Dog Mill is shown and the operation of the mill outlined.
W. H. BOYNTON

Sizing by elutriation of fine ore-dressing products. A. M. GAUDIN, J. O. GROH AND H. B. HENDERSON. *Ind. Eng. Chem.* **22**, 1363–6(1930).—A study has been made of the functioning of the type of elutriator designed by Gross, Zimmerley and Probert (*C. A.* **23**, 4655). Tables are given showing the rates of flow required in elutriators of a given cross section to sep. a given mesh size of particle. Temp. corrections are also given for water and acetone. Non-polar liquids like kerosene cause flocculation of most particles. Heteropolar liquids like alcs. cause flocculation of silicates but not sulfides. Acetone gives results in about one-fourth the time required for water. Microscopic measurements show good agreement between actual and calcd. particle size.
H. C. DOTS

Chemistry of leaching bornite. JOHN D. SULLIVAN. Bur. Mines, *Tech. Paper* 486, 20 pp.(1931).—Bornite can be leached with $Fe_2(SO_4)_3$. The rate of soln. was virtually independent of the strength of $Fe_2(SO_4)_3$ if enough reagent was present. As Fe^{+++} salts reduce current efficiency and necessitate higher current densities in electrolytic pptn. it is desirable to keep their concns. as low as possible. If the Fe^{+++} remained const., the rate of soln. was independent of acid strength (0.25–10%). The rate for

10–28-mesh particles was practically identical with that for 100–200-mesh mineral. Smaller material was attached only slightly more rapidly and larger material only slightly more slowly. Temp. had a marked effect. Leached particles retained practically their original form. The final particle was composed of S and insol. material. H_2SO_4 and air will attack bornite more slowly than $Fe_2(SO_4)_3$. $FeCl_3$ was more effective than $Fe_2(SO_4)_3$. ALDEN H. EMERY

Recovering smelter dust and oxide. N. F. KEPNER, W. ROMANOFF AND C. O. THIEME. *Eng. Mining J.* **131,** 60–4(1931).—The practice and equipment and tech. control in the modern secondary-metal smelter of H. Kramer & Co., Chicago are briefly described. The prepn. of scrap for the smelting furnace and furnace operation are summarized. The dust-collecting equipment is calcd. to be of sufficient capacity to handle the gases and dust from 3 reverberatories or 2 furnaces and a 42-in. blast furnace operating simultaneously. Cr-Ni-Fe alloy flue branches and a manifold were necessary because of excessive temps. A spray chamber with water from a high-pressure pump was necessary. A general layout of the flue system as far as the spray chamber is given and indicates the manner in which the branch flues lead to the manifold "A." Pyrometric control was found necessary to preserve the life of the high-temp.-resistant steel branches. W. H. BOYNTON

The development of the foundry technic during the later years. SIXTEN NILSSON. *Teknisk Ukeblad* **76,** 34–9, 44–7(1929).—An illustrated review. C. A. ROBAK

Air discharge of circular tuyères. RICHARD S. MCCAFFERY AND DANIEL E. KRAUSE. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. **385,** 10 pp.(1931).—The report of a gain in efficiency with lower blast pressure by using a diverging tuyère made it desirable to investigate the shape of the air streams issuing from various types of tuyères. Model tuyères were made a $^1/_8$ scale, and air was supplied at a pressure of $1^1/_2$ in. of Hg. The blast from a single tuyère was discharged into the atm. and a Pitot tube was used to explore the air stream. A diverging tuyère broadens the air stream. The longer the diverging portion of a tuyère, the broader the air stream. The diverging tuyères have considerably less linear velocity than those of the converging type. A diverging tuyère is most efficient when the angle of divergence is between 9° and 10°. The 12° divergence gives a greater discharge for short tuyères but does not give as great a discharge as a 10° divergence when the length is increased to 4 times the throat diam. A converging tuyère with greater velocity causes more turbulence. The benefits derived from the use of a diverging tuyère are probably due to better distribution of air in the furnace. A. W. HOLMES

Open-hearth combustion control. MARTIN J CONWAY. *Iron Steel Eng.* **8,** 29 (1931).—The most important step in open-hearth furnace control is automatic stack draft control. The approximation to perfect combustion and waste-gas control have resulted in increased output and a marked increase in furnace life and lowered fuel costs. The use of control app. requires a trained and intelligent personnel. W. H. BOYNTON

Cleaning, distribution and uses of blast-furnace gas. WILLIAM A. HAVEN AND C. B. THORNE. *Iron and Steel* (*A. S. M. E. Trans.*) **52,** 81–9(1930).—The Fe blast furnace is the largest producer of by-product gaseous fuel of all metallurgical processes. Many American plants use the gas exclusively in boilers. A more advantageous distribution is an important factor in pig-Fe costs. For every ton of pig Fe produced, about 135,000 cu. ft. of gas is generated, with a fuel value of about 90 B. t. u. per cu. ft. From 25 to 35% is required for the stoves. The remainder may be used to generate power, but a more profitable use is suggested in the steel furnaces and coke ovens. These uses involve cleaning, with a cost of 1.179 cents per ton of pig Fe for gas cleaned to 0.15 grain per cu. ft., and 5.455 cents when cleaned to 0.08 grain per cu. ft. The use to which the gas is to be put will det. the degree of cleanliness desired and thus the cost of cleaning. CURTIS L. WILSON

Heating [pig-iron] mixers with blast-furnace gas. K. D'HUART. *Stahl u. Eisen* **50,** 785–8(1930).—The construction of several types of mixer fired with blast-furnace flue gas is illustrated, and a new direct-fired regenerative mixer and ancillary plant is briefly described with reference to diagrammatic plans. B. C. A.

Statistical analysis of blast-furnace data. RICHARD S. MCCAFFERY AND RONALD G. STEPHENSON. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. **384,** 13 pp.(1931).—A preliminary study of the daily operating reports of 15 blast furnaces. Because of the quantity of data and the no. of variables to be compared, the method of elec. tabulating and accounting machines of the International Business Machines Corp. was adopted. The original data were recorded by punching on cards. A sorting machine sorted the cards for the different variables, and a printing machine made a record of sorted cards.

Special comparisons were used in classifying the slag. An inspection of some of the results showed that for each 1% increase of Si in the pig the daily tonnage decreased by 2%. The consumption of coke per ton of Fe is increased 100 lb. for each 1% increase of Si. S elimination varies directly with Si. S in the slag approaches a limit of 2.20% as Si increases to max. of 4.25%. S in the metal does not change materially. The ratio of S in the slag to S in the metal also increases with the Si content of the metal. A. W. HOLMES

Blast-furnace slags. RICHARD S. MCCAFFERY. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 383, 5–26(1931).—A progress report is made on work being done at the Univ. of Wisconsin on iron blast-furnace slags. Both actual blast-furnace slags and slags synthetically produced in the lab. have been used in the studies. At present the viscosity of slags covering the range of silica 25–55, alumina 0–35, lime 25–55 and magnesia 0–20% has been studied. These measurements were made at temps. 1250–1650°. Some of the slag viscosity diagrams are reproduced in the report. A. W. H.

Determination of viscosity of iron blast-furnace slags. RICHARD S. MCCAFFERY, CLARENCE H. LORIG, IRA N. GOFF, JOSEPH F. OESTERLE AND OSCAR O. FRITSCHE. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 383, 27–54(1931).—The app. used in the Univ. of Wisconsin slag viscosity tests is described. An Ajax-Northrup high-frequency induction-type furnace operated from a 35 kv. amp. high-frequency converter supplies energy for heating. The secondary was a graphite crucible and its molten charge. This crucible is supported from the bottom through a graphite support, and water cooled metal connections by a vertical reduction gear, which will revolve the crucible at speeds of 10 to 40 r. p. m. When the slag in the crucible is molten a square graphite spindle is immersed in it. This spindle is suspended by a spring filament and is carefully centered. When the crucible contg. the molten slag is rotated within the furnace at a const. speed, the slag tends to drag the spindle around and displace it angularly with respect to its original position in the molten slag. The angle of displacement is a measure of the viscosity of the slag. Round spindles were tried but were not as accurate because the molten slags did not all wet the graphite and this allowed slip between spindle and slag. A. W. HOLMES

A new arrangement for the granulation of blast-furnace slag with water and air. F. SPIES. *Stahl u. Eisen* 51, 10–14(1931).—The liquid blast-furnace slag is brought together with a small quantity of water in a channel. The excess water runs off through slots at the end of the channel where, through one or more nozzles, compressed air is supplied, which hurls the slag in the supply container. The water content of the finished slag can be regulated by the amt. of water added; it *can be used in cement or brick*. The advantages of this method are the low cost of the outlit and the fact that very little water is required. J. A. SZILARD

Effect of magnesia on slag viscosity. RICHARD S. MCCAFFERY, JOSEPH F. OESTERLE AND OSCAR O. FRITSCHE. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 383, 55–68(1931).—Slags with 5% magnesia are decidedly more fluid than those with zero magnesia and with increasing amts. of magnesia up to 20% the fluidity increases. When magnesia is present increase in temp. causes greater increase in fluidity. When magnesia is present there is not so much difference in viscosity caused by other elements. These results have been detd. on silica-alumina-lime and magnesia melts in which Fe and Mn were absent. A. W. HOLMES

The calibration of reduction rolls for seamless tubes. P. GOROL. *Stahl u. Eisen* 51, 33–7(1931).—Methods are discussed to obtain seamless pipes of any desired size by using reduction rolls. J. A. SZILARD

The iron industry of China. KARL WENDT. *Stahl u. Eisen* 51, 1–8(1931).—The development of the Fe industry, the location of the ore and coal deposits and a description of the foundries in China are given. J. A. SZILARD

The production of high-test cast iron. RICHARD MOLDENKE. *Iron Steel Can.* 14, 1–2, 17–9(1931); cf. *C. A.* 24, 4989.—A review. E. H.

Developments in products at Lukens Steel Company. J. H. MCELHINNEY. *Iron Steel Eng.* 8, 6–8(1931).—A brief review. W. H. B.

Air filtration as applied to the steel industry. M. R. ROBINSON. *Iron Steel Eng.* 8, 15–20(1931).—Air filtration becomes an intimate part of air conditioning and finds an important field to serve in the protection of expensive elec. equipment in the steel industry. Emphasis is placed on the importance and value of air filtration for conditioning the air about the steel mill. Information is included on the cost of four ventilation frequency changer set, showing savings. W. H. BOYNTON

Fundamental and applied research on the physical chemistry of steel-making. C. H. HERTY, JR. *Metals & Alloys* 1, 883–9(1930).—See *C. A.* 25, 478. A. J. M.

Open-hearth steel process as a problem in chemical kinetics. ERIC R. JETTE. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 380, 34 pp.(1931).—An attempt has been made to analyze the complex set of reactions and processes comprised in the open-hearth steel process. The major premise was that the reaction $FeO + C = Fe + CO$ was the rate-detg. reaction. Because of the unknown diffusion consts., variation of catalyst concn., etc., it was not possible to arrive at a complete solution.; nevertheless certain values are gained. From a kinetic standpoint a knowledge of the FeO content is more important than C content. Diffusion consts. are likely to lead to false results. As long as open-hearth practice continues in the use of highly oxidizing finishing slags "overoxidation" is unavoidable. A. W. HOLMES

The design, development and manufacture of special steel castings for locomotive and car construction. H. R. BARTELL. *Eng. J.* (Canada) 13, 677-82(1930).—A review. C. G. F.

The formation and decomposition of cementite. P. PINGAULT. *Compt. rend.* 191, 1007–8(1930).—Pure cementite, prepd. by the action of NaCN upon Fe filings at 650°, was heated in a vacuum at various temps. and subjected afterward to the attack of HNO_3 (d. 1.2). After 10 hrs. at 1000° only faint traces of graphite could be found. After 1 hr. at 1075° the cementite was agglomerated and distinct traces of graphite were found. After 1 hr. at 1175° the cementite was transformed partly into metallic globules having the microscopic characteristics of gray cast Fe and partly into a powder, contg. much graphite. Below 1000°, therefore, the pure cementite may be considered very stable, but as soon as the melting temp. of cast Fe is approached, the decompn. of the cementite becomes rapid. In forming cementite from pure Fe and NaCN in the absence of air, it was found that the cementation of the Fe was negligible at temps. of 600–50° and 850–900°. The same results were obtained in pure and in com. NaCN. Different results obtained in the presence of air are believed to be due to the carbonizing action of the decompn. products of the NaCN. Soft-steel electrodes were immersed in a NaCN bath kept at 650° and a current was passed. The effect varied considerably with the c. d. After 40 hrs. at 1 amp./sq. dm. the anode was much hardened while the cathode remained unchanged. At 20 amp./sq. dm. there was no hardening of the electrodes, but the anode was corroded. At 60 amp./sq. dm. the loss of wt. of the anodes after 15 hrs. amounted to 2.5 g./sq cm. The powder derived from the decomposed anodes contained 6% C and 2–2.5% O. It consisted of cementite detached from the anode on account of the great speed of formation and, on account of its fineness, slightly oxidized by the washing media employed. LEOPOLD PESSEL

Mechanism of the tempering of martensite. P. CHEVENARD AND A. PORTEVIN. *Compt. rend.* 191, 1059-62(1930); cf. *C. A.* 24, 5697.—The phenomena of tempering are complicated by the simultaneous presence of austenite and martensite and the difficulty of obtaining the latter in a pure state. The proportion of austenite was estd. by the dilatometric method and conclusions were thus drawn as to the behavior of martensite itself. The following changes take place simultaneously: Martensite ⟶ cementite + martensite (with less C). Austenite ⟶ cementite + austenite (with less C). Austenite ⟶ cementite + martensite. Some of the physical changes are plotted against the tempering temp., simultaneously with pure martensite and quenched steel. The hardness increases at first because of the fineness of the pptd. cementite particles and the increasing concn. of C in the α phase, but on further increase of temp. it decreases rapidly as a result of the coalescence of the cementite particles. The hardness of the martensitic structure, therefore, passes through a max. As austenite is much softer than martensite, the curve of quenched steel is approx. parallel to that of martensite in the beginning, but it approaches the latter with an increase of temp. in consequence of the decompn. of austenite and merges with it when the change is completed. A similar conformity appears in the dilatometric curves, and should also exist for other phys. and chem. qualities. The corrosion by acids, for instance, is a function of the C content in the α phase, which decreases with rising temp., and is also a function of the no. of cementite particles which pass through a max. A max. of coloration with etching reagents is predicted. LEOPOLD PESSEL

Problems of the metallic state. J. D. BERNAL. *Metallwirtschaft* 9, 983–7(1930).—Although many thermal and microscopic investigations on metals and alloys have been made, the theoretical chemistry of the metallic state has been neglected. After discussing the characteristic properties of metallic atoms and classifying in tabular form the space lattices of the binary alloys of 20 metals, B. concludes that investigation of individual problems is not at present as necessary as a correlation of the structural mech., elec. and magnetic properties of typical metals, compds. and solid solns. CURTIS L. WILSON

Shrinking of plate metals on heating. IKUTARO SAWAI, YOSHIHIRO UEDA AND MORIO NISHIDA. *Z. anorg. allgem. Chem.* **193**, 119–32(1930); cf. *C. A.* **24**, 4497.—Velocity of shrinking of Au and Ag plate was studied in CO_2 and N_2 as well as in air; the results show that O_2 has a profound influence, probably because of the existence of an adsorbed gas layer upon the surface of the metal. Shrinking occurs when $v_2 > v_1$, in which v_2 is the velocity of shrinking and v_1 is the velocity of thermal expansion. In a discussion of theoretical considerations, shrinking at elevated temps. is assumed to be a surface-tension effect. H. STOERTZ

Transformation points in metals. A. SCHULZE. *Z. Metallkunde* **22**, 308–11 (1930).—Conclusion of article previously abstracted (*C. A.* **24**, 3973). This article contains data on the elec. resistance, thermal expansion and thermal e. m. f. of Tl and Co as a function of temp. It is concluded that *Tl has a transformation pt. at 225° and Co at 1128°*. The Tl contained Tl, 99.4, Pb 0.5, Zn 0.1, As 0.02 and Ga 0.01%. Three samples of Co were used, the first was in wire form prepd. from a "pure" powder by sintering, the purity of which is indicated by its temp. coeff. of elec. resistance of 5.92×10^{-3}; the second was prepd. from powder by melting in a quartz tube *in vacuo* and exhibited a temp. coeff. of elec. resistance of 6.58×10^{-3}; the third was technical Co analyzing Co 99.2, C 0.02, Si 0.03, Mn 0.26 and Fe 0.47%. ROBERT F. MEHL

Forming properties of thin sheets of some nonferrous metals. W. A. STRAW, M. D. HELFRICK AND C. R. FISCHRUPP. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. **406**, 14 pp.(1931).—A simple method is described of detg. the forming ability of sheet brass, phosphor bronze and nickel silver which duplicates actual mfg. conditions. Data of direct application in selecting grades, tempers and thicknesses of material for design and manuf. are given in terms of min. radii of 90° forming tools which produce bends without cracking the surface of the materials. Examples are shown of the application of the results in connection with the design of formed parts and forming tools. C. L. MANTELL

Investigations upon the structure of metallic systems by means of x-rays. A. WESTGREN. *Z. Metallkunde* **22**, 368–74(1930).—The usefulness of x-ray detns. of structure in the study of constitution of metal systems is pointed out in detail. The structural analogies already found in the binary systems of Cu, Ag and Au are found to be much more extensive than first thought. The new structural analogies are listed and discussed. This paper is a sequel to those previously abstracted (*C. A.* **23**, 3425, 4915). ROBERT F. MEHL

Metallo-technical Röntgen investigation. New experimental results. A. HERR *Giesserei-Ztg.* **27**, 590–8(1930).—The application of x-rays in detecting defects in large metal parts such as locomotive cylinders is discussed. H. STOERTZ

Effect of surface conditions and electrodeposited metals on the resistance of materials to repeated stresses. R. H. D. BARKLIE AND H. J. DAVIES. *Proc. Inst. Mech. Eng.* (London) **1930**, No. 3, 731–50.—The tensile stress in Ni electrodeposited on steel reduces fatigue limit. The stress increases in a linear manner with the deposition potential. The internal stress can be lowered or eliminated by increasing the temp. and using a. c. superposed on d. c. Electrodeposits of Cu free from internal stress will reduce fatigue limit. Zn and Pb have little effect. Intermediate Pb films between stressed Ni and mild steel insulate the steel from the effects of stressed Ni deposits. The adhesion of the Ni increases with increasing thinness of the intermediate Pb film. Repeated electrochem. treatment destroys the mech. continuity of the surface. An unsuitable cleaning process by permitting occlusion of H during pickling may cause abnormal brittleness. Circumferential grooves have a more serious effect on the safe stress in hard steel than in mild. ANN NICKOLSON HIRD

The properties of forging ingots of electrolytic copper, reverberatory copper, arseniferous copper, aluminum bronze with 4% aluminum in relation to the conditions of working. P. SIEBE AND G. ELSNER. *Z. Metallkunde* **22**, 238–45(1930).—Conclusion of article previously abstracted (*C. A.* **24**, 3976). This portion of the article discusses arseniferous Cu and Al-bronze with 4% Al. The values of tensile strength, elongation, reduction in area and notch-impact strength obtained after various types of forging treatment are listed and a summary table is given in description of the structural changes observed in the 4 types of metal studied with hot- and cold-working and with various types of heat-treatment. *Conclusions.*—At low forging temps. the tensile strength and elongation of a crude ingot are increased but the reduction of area decreased. At higher temps. of heating the decrease in the strength values is greater in the cold-forged material. This is explained by the greater grain-growth in the ingots forged at the lower temps. Cold-drawing in general increases the strength of the cold-forged ingot, but the reduction in area decreases, whereas it remains const. in the hot-forged ingot. R. F. M.

Three crystalline modifications of electrolytic chromium. KUMAZO SASAKI AND SINKITI SEKITO. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding, No. **11**, 482–5(1930); cf. Ollard, *Metal Ind.* (London) **28**, 153(1926); Smith, *Metal Ind.* (London) **28**, 456(1926); Bradley and Ollard, *C. A.* **20**, 2600; Sillers, *C. A.* **21**, 1617.—The authors have confirmed, by x-ray analyses, the existence of the hexagonal close-packed modification, and of the body-centered cubic modification of Cr as well, obtaining a modification of the same type as that of α-Mn, contg. 58 atoms in a unit cube. The Cr was obtained by electrolyzing solns. of $Cr_2(SO_4)_3$ contg. 1–2.5 mols. of Cr and 0.20–0.35 mols. free H_2SO_4, with Cu-wire cathodes and artificial magnetite anodes. Fe, Zn, Co and Cr cathodes gave the same results. For the x-ray spectrograms the anti-cathode was of Cr, and the spectra were obtained of the deposits on the wires to avoid transformation of the modifications. At c. ds. below 15 amp./sq. dm. the body-centered cubic form was deposited, above 18 amp./sq. dm. the hexagonal close-packed form, and at intermediate c. ds. a mixt. of the 2 forms. The temp. had to be kept below 20° for the hexagonal form to be given. At 26° the body-centered cubic form only was given even at a c. d. as high as 30 amp./sq. dm. The variety (violet or green) of $Cr_2(SO_4)_3$ and its concn. in the soln. were without effect on the structure of the deposits. The lattice const. of the body-centered form was calcd. to be 2.877 ± 0.003 A. U. The axial ratio of the hexagonal form was found to be 1.626, and the distance between neighboring at. centers 2.717 A. U. The lattice const. of the cubic form of the α-Mn type was found to be 8.717 A. U. The sp. grs. of the above forms are calcd. to be 7.21, 6.08 and 7.48, resp. Spectrograms of the hexagonal and the α-Mn forms taken at intervals showed that, at room temp., both changed to the body-centered cubic form, the former after 40 days and the latter after 230 days after deposition. This showed the different spectra to be those of different modifications of Cr and not due to oxide inclusion in the deposits.

EDWARD B. SANIGAR

Distribution of crystals of chromium electrodeposited in thin plates. D. T. EWING, H. E. PUBLOW AND C. D. TUTTLE. *Mich. Eng. Expt. Sta., Bull.* No. **33**, 20 pp. (1930).—The purpose of the investigation was to study the nature of crystal formation of metals deposited electrolytically. The work was limited to the initial stages of deposition in order to note the effect of the compn. and the phys. condition of the basis metal upon the nature of the deposit. The compn. of the plating soln., the c. d. and certain other factors were not varied, but the temp. and time were varied. A study was made of the crystal growth of Cr deposited on carefully polished surfaces of steels with C contents of 0.20, 0.85, 1.20 and 1.50% and on Armco iron. The time of plating varied from 15 sec. to 8 hrs., and temps. of 45° and 55° were used. The Cr plating soln. contained 250 g. CrO_3 and 2 g. Ba_2SO_4 per l. The initial Cr deposits were not microscopically uniform; invariably the Cr deposited first upon the cementite and spread rapidly to the ferrite within the pearlite areas. This effect was noted in the samples of low C content as well as in those in which cementite was concentrated within the crystal boundaries. It was found that Cu and Ni, however, deposited evenly, not selectively, over the surface of the steels, and Cr deposited over the Cu and Ni was uniformly distributed over the metal surface. The color of the deposits changed during the first stages of deposition; up to 15 sec. the deposits were dull, after which they became brighter. At the higher temp. (55°) the changes noted above were accelerated and the basis metal was more uniformly covered in shorter time. The higher temp. also decreased the tendency for Cr to deposit selectively. Short cracks formed after the first few min. of deposition; no correlation was found between the cracks and the crystal boundaries of the basis metal. Thirty-three photomicrographs are included of the steels used as basis metals and of the deposits obtained. E. B. S.

The electrical conductivity of copper. G. ELSNER AND P. SIEBE. *Z. Metallkunde* **22**, 397–401(1930).—A study of the influence of cold-working and annealing upon the elec. cond. of Cu. Two types of electrolytic Cu (99.90 and 99.80% Cu) and two types of refined Cu (99.80 and 99.64% Cu) were studied. The Cu was in the form of wires, heated at temps. from 100° to 800° and cold-drawn from 30 to 97%. The heat treatment for the production of max. cond. is in the moderate temp. ranges. With decreasing purity this temp. is displaced downward. The decrease in elec. cond. after the attainment of max. value depends probably upon structural conditions. Cold-working in general diminishes the cond. The differences in cond. produced by the preceding heat treatment more or less completely disappear in the highly worked material; this depends upon the degree of purity. In the refined Cu, with low purity, the effect of heat treatment still appears after cold work, a pptn. process probably interfering.

ROBERT F. MEHL

The solubility of silver in copper. F. MÖLLER. *Metallwirtschaft* **9**, 879–85(1930).—

The soly. of Ag in Cu in Cu-rich alloys was detd. by resistance measurements on wires contg. 4, 5 and 6% Ag, at different temps. A break in the temp.-resistance curve occurred at the point where there was a transition from solid soln. to mixed crystals for each alloy. Plotting this transition temp. against the compn. of the alloy gave the boundary of the mixed-crystal field. In the same expts. the solid-liquid line was obtained. The triple point occurs at 7% Ag. The discrepancies between these results and those obtained by Weinbaum (*C. A.* **24**, 1607) by x-ray and hardness measurements on quenched alloys, and the mechanism of the process of quenching are fully discussed. CHANNING W. WILSON

Thermomagnetic property of manganese. YOSOMATSU SHIMIZU *Sci. Repts Tohôku Imp. Univ.* 1st Ser. **19**, 411–7(1930).—The modifications of Mn were studied by detg. its magnetic susceptibility at different high temps. The purity of the metal used was 99.9%. A specially designed elec. furnace, using a carborundum tube as resistance element, was used in conjunction with a du Bois electromagnet. The magnetic susceptibility of Mn of 99.9% purity at room temp. was found to be 7.55×10^{-6}, a value which is smaller than that obtained by previous investigators working with a less pure material. At 810° the magnetic susceptibility undergoes an abrupt increase. The change from α- to β-Mn takes place at that point. At 1100° there occurs another similar increase, indicating the change from β- to γ-Mn. The magnitude of the change in susceptibility at the $\beta \longrightarrow \gamma$-transformation is much greater than that at the $\alpha \longrightarrow \beta$-transformation. LEOPOLD PESSEL

Properties of pure nickel. LOUIS JORDAN AND WM H. SWANGER, *et al* *Bur. Standards J. Research* **5**, 1291–1307(1930). –Rather pure electrolytic Ni was further purified by annealing in H. A study was made of suitable refractory crucibles and of melting conditions to produce extremely pure, compact metal. The ingots finally prepd. had a purity of 99.94%, contg. not more than 0.001% O. Details of the methods are given which lead to the following values: density 8.907 g./cc. at 23° (as cast), 8.901 (worked and annealed), 8.917 (calcd. from lattice dimensions); length of side of unit cube (face-centered) 3.525 A. U.; m. or f. p. 1455° (International Temp. Scale), elec. resistivity 7.236 microhms/cm. at 20° (annealed); temp. coeff. of elec. resistance 0.0067 ohm per degree per ohm at 0° (from 0° to 100°); satn. value of intrinsic induction 6150 gausses; magnetic transformation 370–380° (by magnetometer measurements); thermal transformation 350° (by thermal analysis); thermal e. m. f. with Pt 1.485 mv. at 100°, 6.165 mv. at 500°, 12.130 mv. at 1000° (Ni is thermoelectrically neg. to Pt); av. coeff. of thermal expansion: 13.3×10^{-6} (25–100°), 14.4×10^{-6} (25–300°), 16.5×10^{-6} (300–600°), 17.8×10^{-6} (600–900°); hardness: Baby Brinell 68–78, scleroscope 5.0, Rockwell 42–44; tensile strength 46,400 lb./sq. in. Curves are reproduced showing the ultra-violet reflectivity. LEOPOLD PESSEL

Cadmium bearing metal. A. J. OCCLESHAW. *Commonwealth Eng.* **18**, No. 5, 177–9(1930).—An alloy contg. Cd 96.7, Cu 3.1 and Mg 0.2% has the properties requisite for a high-class bearing metal. Under the microscope 2 constituents are visible, one being a network of a relatively hard high-Cu material, and the other a matrix of relatively soft low Cu eutectic. Brinell hardness is 48, while tin-base alloys have hardness of 26.5. The freezing range is 380–320°, which is about 100° higher than that of tin-base metals. The Cd alloy casts well but not quite as sharply as tin-base alloys. The Cd alloy contracts more on solidification. Tests made on properties as bearing metal indicated that it was equal to phosphor bronze, both showing small distortion at 2500 lb. per sq. in. It is better than tin and lead white bearing metals which rarely run on test machine at 1500 lb. per sq. in. without distortion or flow. The Cd bearing metal is suitable for use at high loads and speeds. A. W. HOLMES

Strengthening in reversed loading and gliding resistance. P. LUDWIK. *Z. Metallkunde* **22**, 374–8(1930).—The relations between the yield pt., ultimate tensile strength, breaking strength, hardness and the fatigue limit were studied. Hardness detns. during the fatigue test upon electrolytic Cu showed increases up to 6.5% at stresses at the fatigue limit. At stresses smaller or greater than the fatigue limit smaller hardness increases were observed. Expts. were made to det. the effect of notches upon the fatigue limit, and the sensitivities of different industrial alloys were studied from this standpoint. The corrosion fatigue limits of several non-ferrous alloys were detd. Comparable expts. with bending fatigue and torsional fatigue with polished specimens gave a ratio of torsional fatigue limit to bending fatigue limit of 0.577 ± 6%, which is the same ratio as the yield points on torsion and tension static loading. Cast iron gave a different ratio because of the internal notch effect induced by the graphite flakes. With similar types of notches sensitivity on torsion was found to be only 0.575

that on bending. The amt. of exptl. data is too great to be included in an abstract. R. F. M.

Strengthening by reversals of stress. W. SCHWINNING AND E. STROBEL. *Z. Metallkunde* **22**, 378–81(1930).—Steel with 0.05% C and brass with 72% Cu were studied by subjecting wires of these materials to reversals of stress (bending) and then detg. the ultimate tensile strength, the yield point and the elastic limit. Data collected are given graphically. More data and conclusions will be given in a concluding article. ROBERT F. MEHL

Bearing properties affected by variations in composition. CLAIR UPTHEGROVE. *Foundry* **59**, 72–4(1931). LEOPOLD PESSEL

Hydrogen development in pickling. HEINZ BABLIK. *Korrosion und Metallschutz* **6**, 223–8(1930).—The H_2 development of 4 kinds of Fe sheet varying in chem. compn. was detd. in HCl and H_2SO_4 of varying concns. and the results were plotted in curve form. Although the chem. compn. of the specimens showed only relatively small differences, considerable differences of the speeds of soln. existed. The latter also depend upon a time factor which is different with each material. The speed of soln. is higher at the beginning of the attack, but soon drops to a fairly const. value. Under the conditions under which H_2SO_4 is used, it develops considerably more H_2 than does HCl. The relative soly. of the 4 kinds of Fe remained the same in both acids. The influence of inhibitors upon the H_2 development and the influence of HCl and H_2SO_4 upon the quantity of absorbed H_2 are discussed. The necessity of pickling a sensitive material with nothing but HCl is emphasized. LEOPOLD PESSEL

Sheet and tinplate rolls. An investigation into the roll loads, stresses and the cause of roll breakage. J. SELWYN CASWELL. *Proc. S. Wales Inst. Eng.* **46**, 813–34 (1930). cf. *C. A.* **24**, 5694.—Discussion. ALDEN H. EMERY

Metal spraying. S. H. GRIFFITHS. *Proc. Staffordshire Iron and Steel Inst.* **45**, 60–5(1929–30).—The most common type of metal-spraying pistol is illustrated and its operation and design are discussed. The careful control of the sandblasting operation previous to the application of the metal spray is of the utmost importance in attaining an adhesive coating. The advantage of metal spraying is pointed out for *in situ* application. DOWNS SCHAAF

The influence of superheating molten cast iron. J. E. HURST. *Foundry Trade J.* **43**, 55(1930).—Cast Fe was superheated to as high a temp. as possible in a coke-fired crucible furnace, approx. 1550–1600°, and then cast on a centrifugal-casting machine. The tensile strength, modulus of elasticity, and Brinell hardness were slightly higher than those of Fe cast at 1200–1250°. Loss of Si in the superheated material caused easy machineability and complete loss of chill, from which the conclusion is drawn that superheating produces a grayer iron. Cf. *C. A.* **24**, 808. CURTIS L. WILSON

Simple methods of improvement and control of gray-iron manufacture. L. F. C. GIRARDET. *Trans. & Bull. Am. Foundrymen's Assoc.* **1**, 624–43(1930).—Practical control methods for securing the desired properties in gray iron castings are discussed and described under 3 classifications: (1) mech. properties, (2) metallographic structure, (3) chem. analysis. The Fremont shear test is advocated as a means of showing the properties of the casting itself. C. L. READ

Aluminum improves malleable-cast-iron properties. JOHN H. HRUSKA. *Foundry* **59**, No. 1, 70–1(1931).—Expts. were carried out on a large scale under mfg. conditions to det. the influence of Al upon malleable cast Fe. The material, to which Al was added in form of Al shot of 92.86 Al, was made in a 25-ton air furnace and one 800-lb. ladle of molten metal was used to pour 11 sets of test bars. After malleablizing the bars were machined to size and tested for tensile and bending properties. Up to approx. 0.1% Al the fractures appear normal. At 0.1–1.0% Al the fractures become gray and then dull with irregular crystn. Excess of Al (above 0.1%) changes the round globules of graphite into irregular, flaky shapes. A rapid change in phys. properties takes place. Elongation and reduction of area become extremely low when Al exceeds 1.0%. Heat treatment cannot restore any of these properties in bars contg. more than 0.5% Al. A small addn. of Al, 0.01–0.05%, has a marked beneficial effect upon elongation, reduction of area and tensile strength. LEOPOLD PESSEL

Nickel-vanadium and nickel-molybdenum cast irons. I. Nickel-vanadium cast irons. JEAN CHALLANSONNET. *Rev. métall.* **27**, 573–603; *Bull. assoc. tech. fonderie* **4**, 291–315(1930).—A study was made of the effect of Ni and V and Ni-V mixts. (1) on a synthetic cast iron contg. 3.70% C and 0.08% Si and (2) on 3 types of common cast irons. The synthetic cast iron was melted at 1700° in a high-frequency furnace and alloyed at 1600° with 1 and 2% Ni, 0.25 and 0.50% V and with Ni-V mixts. in the percentage concns. 1 + 0.25, 1 + 0.5, 2 + 0.25, 2 + 0.5. All these alloys were sand-

cast at 1500° in 2 cylindrical molds of 25 and 8 mm. diam. Dilatometric and micrographic investigation showed: Ni did not displace the Curie point (200°), while 0.25 and 0.5% V lowered it to 160° and 130°. The Ac_1-point (700°) and the Ar_1-point (630°) were both lowered by Ni but not by V, while in the Ni-V alloys the V overcame the lowering effect of Ni. With Ni alone, graphitization on heating begins at temps of 1000° and lower, while V alone prevents graphitization (at least up to 1100°). In Ni-V cast irons V raises the temp. of beginning graphitization, 0.25% V neutralizing the lowering effect of 1% Ni. The amt. of graphite pptd. was about 0.4% when 2% Ni was added. The special alloys made with com. cast irons contained the same percentages of Ni, V and Ni-V, but the percentages of C and Si were 3.55 + 1.46 for type A, 3.7 + 2.7 for type B, and 2.5 and 2.5 for type C. The amts. of Mn, P and S were in all cases approx. the same: 0.5% Mn, 0.08% P and 0.035% S. The samples were melted in a gas furnace of 45 kg. capacity and sand-cast in a mold of special construction, providing specimens for mech., dilatometric and phys. tests. The dilatometric curves obtained with thin rods (in which cooling had taken place rapidly) showed that for alloy-type A addn. of 1 and 2% Ni led to a lowering of the cementite content, at the same time producing a martensitic structure. The heating curve indicated that the temp. of beginning graphitization falls below the Ac_1-point. Addn. of 0.25 and 0.5% V represses the formation of graphite and does not favor the martensitic quench. The Curie point is lowered 20° and 70° while the temp. of beginning graphitization on heating is raised from 900° to 925° and 975°. In the specimens contg. both Ni and V, the latter opposes the graphitizing effect, of Ni while Ni does not influence the effect of V on cementite. In cast irons of type B and C, V does not noticeably raise the temp. of graphitization. The effect of different rates of cooling was studied by providing the mold with a special limb of regularly decreasing width, in such a way that the cooling was fastest at the bottom (thickness 3 mm.) and slowest at the top (thickness 35 mm.). The lower portions were hardest and showed mostly the structure of white cast iron, particularly in those alloys contg. V, either alone or with Ni, while in the thicker sections there was found mottled and (or) gray cast iron. The curves obtained by plotting the Brinell hardness as a function of the thickness showed that Ni alone tends to equalize the hardness in the different layers, its effect being least in alloys of type B. The effect of V on the hardness is, for identical C content, greater the lower the percentage of Si. The amt. of Si remaining the same, V produces greater hardness the lower the percentage of C. In cast irons contg. both Ni and V, Ni opposes the quench-hardness of V, the more so the higher the C and Si content of the alloy. With regard to the tensile strength and the resistance to shearing the improvements in the cast irons can be traced (1) to the refining action of Ni on the pptd graphite and (2) to the increase in combined C content caused by the V. In alloys of type B the influence of V is less marked than in alloys of type A, because of the greater Si content and the correspondingly smaller quantity of combined C in the alloy. H. S. v. K.

Oil-hardening and air-hardening cast iron. J. E. Hurst. *Foundry Trade J.* **43**, 385–6, 395–6; *Iron and Steel Ind. and British Foundryman* **4**, 91–5(1930). The strength properties of cast Fe contg. 1.32–3.37% Ni and 0.44–0.61% Cr were investigated as cast centrifugally, after hardening by quenching in oil and air blast, and after tempering. The Brinell hardness increased from 236 to 259 for the specimens as cast up to 460–474 after quenching in oil, from 850° to 875° and to 407 after quenching in air from 875°. The hardness diminished progressively upon tempering in a salt bath down to 342 for a tempering temp. of 495°. The tensile strength decreased from 21.3–24.6 tons per sq. in. as cast to 13.85–15.4 for the quenched material, recovering to a max. of 22.5–25.4 after tempering at 375°. Microscopic examn. showed the structure as cast to be pearlitic, after hardening somewhat martensitic, and after tempering sorbitic. Curtis L. Wilson

The problem of age-hardening on the basis of experience with iron alloys. W. Köster. *Z. Metallkunde* **22**, 289–96(1930).—The changes in properties in Fe alloys resulting from quenching from the eutectoid temp. and subsequent storage at room temp. or at slightly elevated temps. (*Vergütung*) are discussed on the basis of the systems Fe–C, Fe–N, Fe–Cu. These changes are similar to those exhibited by the well-known age-hardening Al alloys of the duralumin class. The changes in properties of iron and steel following cold deformation and storage at room temp. and at slightly elevated temps. (*Altern*) are likewise discussed. It is concluded that these changes may also be explained upon the basis of a pptn. process. Robert F. Mehl

The theoretical foundations of age-hardening of the duralumin type in ternary systems upon the basis of phase relationships. E. Scheil. *Z. Metallkunde* **22**, 297–302(1930).—It is proposed that the cryst. phase exhibiting a metastable satn. surface

defines the course of pptn. of 2 types of cryst. phases from a supersatd. solid soln. The course which the compn. of the solid soln. describes during pptn. is given with simple assumptions for 3 basic cases. The conditions are given for the dissolving of one type of crystal. A special case is described of significance for the hardening of alloy steels.
ROBERT F. MEHL

Change of density in iron and steel caused by cold-working and by tempering. KANZI TAMARU. *Sci. Repts. Tohoku Imp. Univ.* 1st Ser., 19, 437–48(1930).—Armco Fe of a com. grade was forged, annealed, cold-rolled and tempered at different temps. Its d. was decreased by cold-working 0.12%. When tempered at different temps. the d. shows a max. at 150° and a min. at 400°. At higher temp. the d. increases until it resumes the value which it had before rolling. The hardness shows corresponding changes at 150° and 400°. Steel also shows a similar change, but smaller in magnitude. In electrolytic and Armco Fe, which were remelted in a vacuum, the change in d. due to cold-working and that due to tempering were very small. In the case of the same metals, which were remelted in air, the d. is normally decreased by cold-working. This seems to be due to the soundness of the ingots which results from the deoxidizing agents. In the case of Armco Fe which underwent a high degree of cold-working and was more compact, the slight initial increase of d. is due to the ordinary effect of tempering and the following decrease of it up to 400° is to be attributed to the increase of available internal stress at the cost of an unstable one. The increase of d. at a higher temp. is caused by recrystn. and the release of internal stresses. The max. and min. of d. of 0.1% C steel are explained in the same way as those of Armco Fe. Their magnitude diminishes with an increase of C, being hardly noticeable in 0.2 and 0.4% C steels. This is due to the difficulty of removing internal strains in steels contg. hard cementite in larger amts.
LEOPOLD PESSEL

The structures of the high-chromium stainless steels and irons. EDGAR C. BAIN. *Blast Furnace Steel Plant* 18, No. 11, 1690–7; *Heat Treating and Forging* 16, 1419–26 (1930). A brief compilation is made of the structural nature of these irons and steels.
J. B.

Heat resistance of aluminum steels and aluminum coats over iron. A. HAUTTMANN. *Stahl u Eisen* 51, 65–7(1931).—The heat resistance of Al steel alloys was measured by the amt. of O taken up in g. per sq. m. in 48 hrs. when heated in air in an elec. furnace at 1000°. The alloys were prepd. from Armco-Fe and ferro-aluminum. The heat resistance of the alloys as a function of the Al content shows a sudden increase between 4 and 9% Al. With 0% Al the increase in wt. is 45.7 g./sq. m.; with 1.84% Al, 36.2 g./sq. m.; with 3.72% Al, 31.5 g./sq. m.; with 9.44% Al, 0.57 g./sq. m.; with 22.91% Al, 0.29 g./sq. m.; and with 38.32% Al, 0.14 g./sq. m. After exposure the first 3 samples were covered with a heavy grayish black layer of Fe-scale. The last 4 samples were covered with a thin layer of red to white Al_2O_3. It is assumed that the protective effect of the Al is a reduction of the Fe_3O_4 formed by at. Al to Fe, with the formation of Al_2O_3. It was also found that up to 4% Al the sp. gr. of the alloy corresponded to the calcd. values. Above 4% the sp. gr. detd. is higher than the calcd. values. This indicates that alloying causes an increase in density. The more densely packed atoms may account for the increased heat resistance. Two methods for Al coating were investigated: the coating by heating Fe rods in powd. 52 or 59% ferro-aluminum and the coating by dipping the rods in molten pure Al. The samples prepd. by the 2 methods were compared for heat resistance at 1000°. In this case not the increase in wt. but the time required to develop Fe_3O_4 blooming on the surface was taken as the measure of heat resistance. The protective layers were destroyed more quickly than expected because of the formation of cracks in the coating surface. Of the 2 types of coatings the one obtained by heating the Fe rods in powd. ferro-aluminum (59%) for 300 hrs. at 1000° was the best. Curves are given showing the increase in the Fe thickness and the depth of the diffusion layer as function of the heating period temp.
J. A. SZILARD

Aging of iron and steel. R. F. MEHL. *Iron and Steel Can.* 13, 265–9(1930).—A brief review, especially of aging theories.
ROBERT F. MEHL

The age-hardening of steel. G. SACHS AND W. STENZEL. *Metallwirtschaft* 9, 959–65(1930).—The fact that steel becomes harder after cold work and subsequent aging at room temp. or tempering at low temp. has been known since the beginning of testing materials. That it also becomes harder upon quenching from below A_1 and subsequent aging has been recognized only recently. This phenomenon is considered analogous to the age-hardening of duralumin. Expts. were made to det. the effect of degree of cold work, time and temp. of tempering, and whether "work-aging" might not be considered simply "quench-aging" accelerated by cold work. Speci-

mens of a soft 0.04%-C iron wire were annealed at 940° and cooled slowly. For work-aging, they were deformed by twisting, and the tensile strength was measured after aging at various temps. for various lengths of time. While the original annealed material showed no improvement with time, the cold-worked material increased in strength, aging most rapidly at 100°. For quench-aging, pieces were heated to 700° and quenched in water. In both types of aging the max. effect was reached at room temp. only after days or even months, while at 100° it was reached in a few min. Work-aging occurred up to 400°. With quench-aging, no effect was noticed above 120°. Both aging effects seemed due to pptn. from supersatd. solid solns., pptn. taking place, however, at different velocities. CURTIS L. WILSON

X-ray study of grain size in steels of different hardness. W. A. WOOD. *Phil Mag.* **10**, 1073–81(1930).—A Moll microphotometer is used to det. the half-breadths of the Fe lines. The relation of particle size to the breadth of x-ray interference lines is applied. A relation is found to exist between the measured half-breadths and the hardness nos. of the various steels investigated. A definite linear relationship is found between the hardness and the inverse square of the particle size. This relationship is discussed and the relation may be explained on the assumption that the hardness varies inversely as the superficial area of the grains. The data are given. W. E. V.

Transformation and constitution of high-chromium steels. TAKEJIRO MURAKAMI, KOJIN OKA AND SEIJI NISHIGORI. *Tech. Repts. Tôhoku Imp. Univ.* **9**, 405–45(1930). The transformation and constitution of high-Cr steels contg. 10–30% Cr and less than 1.1% C were investigated by magnetic, dilatometric and microscopic methods. By means of magnetic analysis isothermal curves for the A_2 point were obtained, its relation to the compn. of the steel was shown, and the compn. ranges, in which the lowering of the transformation takes place, were detd. The A_2 point descends with increasing Cr content when the C content is const., while it rises with increasing C content when the Cr content is const. In the same alloy the Ar″ change increases in magnitude as the max. heating temp. rises or the cooling rate increases, though in high Cr steels, in which no γ phase is formed, no transformation is observable. The Ar″ transformation decreases in magnitude with increasing Cr, when the C content is const., while the transformation is more readily lowered in medium-C steels than in high or low-C steels when the Cr content is const. By measurement of the thermal dilation with slow rates of heating and cooling the A_2 and A_1 points were detd. When the C content is const., the magnitude of the A_1 and A_2 transformations gradually decreases, until it vanishes, as the Cr content increases. When the Cr content is const., the A_2 transformation increases in magnitude and its beginning temp. on heating descends, as the C content increases. The temp. of the transformation rises gradually at first and then rapidly as the Cr content increases. When the Cr content is const. the A_2 transformation increases in magnitude and its beginning temp. on heating descends as the C content increases. These relations were also shown with the isothermal lines for the A_1 point. By means of microscopic observation the section diagrams for const. C content and those for const. Cr content were constructed. By means of isothermal diagrams the change of structure accompanying the changes of temp. and compn. is described in detail. A general diagram was constructed and conclusions are drawn as to the process of crystn. of several alloys belonging to the resp. fields. The influence of different heat treatments upon the change of microstructure of the typical alloys is illustrated by means of photomicrographs. LEOPOLD PESSEL

Chromium cast steels resist heat and corrosion. H. D. PHILLIPS. *Foundry* **59**, 65–9(1931).—A review of the chem., phys. and metallurgical characteristics of these materials, with special consideration of their casting and heat treatment. L. P.

Nickel steels. The effect of nickel on the heat treatment and physical properties of steel. V. N. KRIVOBOK. *Iron & Steel Can.* **13**, 219–20(1930).—Ni steels with 2.5–3.5% Ni have the same metallographic constituents as the C steels, yet the mech. properties are much improved. Most Ni steels contain 0.5–5.25% Ni and 0.20–0.50% C. One % of Ni lowers the Ac_3 transformation about 45°F. (25°C.), and the Ac_1 only 18°F. (10°C.) Ni retards the grain growth. G. T. MOLOK

Thermo-diffusion of elements in steel. JOHN H. HRUSKA. *Heat Treating and Forging* **16**, 1397–9(1930).—A brief summary. J. BALOZIAN

Corner ghost in steel ingots. SOJI MAITA. *Blast Furnace Steel Plant* **18**, 1701–5 (1930).—Corner ghost may occur in all kinds of steel because they are caused by stresses. Chem. compn. of the steel also affects the formation of corner ghost. A slow and controlled cooling may reduce or eliminate the corner ghost in steels. G. T. MOLOK

Effect of heat treatments on efficiency of high-speed steels. ERDMANN KOTHNY. *Iron Age* **126**, 1848–52(1930).—Results of tests are given which show that the cutting

efficiency of high-speed tools working hard and medium-hard steels, can be considerably increased by tempering at 590°. R. S. DEAN

The selection and heat treatment of gear steel. E. F. DAVIS. *Fuels and Furnaces* 8, 1341–8, 1385(1930).—The chem. compn. and hardness of various gear steels used in the automotive industry, with their quenching temps., are given. The 3½% Ni steel is cited as being the most extensively used, and the 5% Ni steel as the best of all gear steels from the standpoint of impact strength and fatigue properties. C. L. W.

The mechanism of quenching high-carbon steel tools. PERCY J. HALER. *Fuels and Furnaces* 8, 1653–9(1930).—The methods of quenching steel tools of various shapes are discussed with reference to plunging velocity and distortion. The effects of low and high plunging velocities upon the stream lines in the cooling media are illustrated. CURTIS L. WILSON

Hot-hardness characteristics of some modern tool steels and alloys. E. G. HERBERT. *Proc. Inst. Mech. Eng.* (London) 1930, No. 3, 681–92.—Hot-hardness of tool steel may be greatly modified by a superhardening process, produced artificially or as a result of abrasion by the chip in normal cutting. In superhardened steel max. hardness occurs just under the skin. Alloy steels are capable of greater induced hardness than plain C steels of the same original hardness, an important quality in cutting hard material where the tool becomes superhardened. Even a water-cooled tool may be heated above its softening temp. while cutting. Co tool steels such as "S. O. B. V." show abnormally high induced hardness and a tool life 84% higher than others. Hot-hardness curves, obtained by the Herbert Pendulum Hardness Tester, are given for "Widia," both heating and cooling, up to 800°. Hot-hardness which fell off at 600° is regained on cooling. Hot-hardness curves are given comparing nitrated steel, high-speed steel and high-C steels up to 600°. The hardness due to the superhardening by the Cloudburst Process persists up to 600°. Comparison curves of hardened and superhardened modern tool steels are given. ANN NICKOLSON HIRD

Influence of the atmosphere on the scaling of mild steel. W. H. BLACKBURN AND J. W. COBB. *J. Soc. Chem. Ind.* 49, 455–62T, 463–6T(1930); cf. *C. A.* 21, 1437.—Small specimens of mild steel were heated for 3 hrs. at 1000° in various atms. and the increase of weight was detd. The loss of metallic iron, when no excess of O was present, was found to be 0.43% with oil as fuel and 0.24% with coke. With 3% O in the atm. the losses were 1.27% and 1.09%. The exclusion of O is of the greatest importance, if scaling is to be minimized. The addn. of 0.5% O results in rapid scale formation. The mixing of the fuel gas with O and the elimination of free O should be completed before the metal is reached. In the absence of free O scaling was definitely lessened by fuels which were rich in C and low in H. The use of high-temp. coke with a low moisture content is recommended. The influence of the addn. of various reducing gases to the furnace atm., upon complete prevention of scaling and upon 50% reduction of scale formation, was detd. The amt. of reducing agent necessary to secure complete absence of scaling or even a reduction to 50% was much larger than could be used in ordinary practice, representing a quantity of potential heat of the same order as that of the primary fuel. H was the most effective agent for the complete prevention of scaling, involving the least thermal expenditure, while CO involved the greatest. Even with H as anti-scaling agent, however, the thermal expenditure amounted to 1.3 or 0.8 times the thermal value of the fuel, depending on whether oil or coke was used. The thermally stable methane was much less effective than either ethylene or acetylene, which are both readily decompd. by heat. The free C (soot), however, present in a smoky atm., was found to have a negligible effect in preventing scale A clear atm., with the same reducing gases, CO and H, was found to be equally effective. In adding CO and H to the furnace atm., the former was found to be more efficient up to the point where scale formation was reduced 43%. Beyond this, H was more efficient. There seems to be no ground for assuming that a smoky reducing flame from bituminous coal would be any more effective in minimizing scaling than a clear reducing flame from coke. The "neutral" atm. from coke would be definitely less scaling than that from coal on account of the lower content of water vapor. Also in *Blast Furnace Steel Plant* 19, 273–6(1931). LEOPOLD PESSEL

steels. S. J. HEWITT. *Ind. Chemist* 7, No. 80(1931); cf. *C. A.* 24, 1325. E. H.

Nitride hardening of alloy steel for Diesel-engine use. C. R. ALDEN. *Oil and Gas Power* (*A.S.M.E. Trans.*) 52, 57–63(1930).—The process of nitriding, or surface-hardening special steels at a low temp. by the action of anhyd. NH_3, is described and illustrated, together with the sequence of operations preceding nitriding. The properties of nitrided Nitralloy steels which make them valuable on various parts of engines

are discussed in detail, such as extreme surface hardness; resistance to wear, scoring, abrasion and corrosion; min. distortion in hardening; hardness maintained at high temp.; and machineability and forgeability. C. L. W.

Alloys of the transition elements. A. WESTGREN. *Metallwirtschaft* 9, 919–24 (1930).—In a comprehensive review of the work of various investigators upon the at. structure of the transition elements and the space lattice of their intermetallic compds., W. concludes that the existing data are not yet sufficient to create a complete and harmonious picture of the conditions under which these elements react in their alloys. CURTIS L. WILSON

Aluminum and aluminum alloys as materials of construction in the chemical industry. DORNAUF. *Metallbörse* 20, 1913(1930).—Experience in using pure Al, Al-Si and Al-Mg alloys is described. Duralumin and Al-Cu are not useful, but must be plated with pure Al. Pure Al (99.5–99.8%) is used to handle concd. HNO_3, org. compds. and in the dairy, brewing and food industries. Its disadvantages are poor casting properties and low tenacity. Al-Si and Al-Mg alloys have twice the strength of pure Al, cast well, and have as high chem. corrosion resistance. The Si alloy is used for valve bodies, stirrers, mixers, filter frames, retorts, evaporators, acid equipment and contact app., and the Mg alloy for pump cylinders, elevator buckets and stills. Often lab. corrosion tests give results different from actual practice, because of voltage produced under liquids by contact with other metals or because of welding. E. M. S.

Casting studies on light aluminum alloys. Influence of the chemical composition. ANDRÉ COURTY. *Compt. rend.* 191, 1128–30(1930); cf. *C. A.* 24, 3475.—Al-Si, Al-Cu and Al-Zn alloys of varying compn. were examd. by a method described previously. The following conclusions were reached: In detg. the casting qualities it is necessary to consider the d. of the metal as well as its compn. In the light Al alloys investigated, the "castability" diminishes, within the proximity of the range of pure metal, with an increase of metals in solid soln. In the Al-Si alloys, in spite of the rapid elevation of the fusion point and the distinct decrease in d., the "castability" was found to be superior in the high-Si alloys (up to 21.72% Si) as compared with the eutectic (13% Si). In the Al-Cu alloys the alloy of 6% Cu has the "castability" of Al and the alloy of 12% Cu surpasses in "castability" pure Al by 20%. Within the large zone of the solid soln. diagram of the Al-Zn alloys the "castability" is diminished with an increase in Zn, in spite of the rapid increase of the d. It requires 30% Zn to obtain an alloy of the "castability" of pure Al. LEOPOLD PESSEL

Constitution of high-purity aluminum-titanium alloys. WM. L. FINK, KENT R VAN HORN AND P. M. BUDGE. *Am. Inst. Mining Met. Eng., Tech. Pub.* No 393, 18 pp.(1931).—A survey of the existing literature showed that the constitution of the binary Al-Ti system had not been definitely established. The present investigation of this system included thermal, microscopic and x-ray studies of a no. of high-purity alloys. Cooling curves are not reliable for the detn. of the liquidus because the thermal point representing primary crystn. in the region investigated is weak and lowered by undercooling. Accurate results were obtained by detg. the soly. of $TiAl_3$ in Al by chem. analysis of the supernatant melt. The constitutional diagram for Al-rich Al-Ti alloys is given. The Al-Ti constituent occurring as plates in the Al-rich alloys was chemically sepd. and found to have the compn. represented by the formula $TiAl_3$. X-ray diffraction data were obtained by the powder, Laue and rotating-crystal methods. Diffraction patterns showed that $TiAl_3$ crystals are tetragonal with lattice dimensions of $a_o = 5.424$, $c_o = 8.574$, $(c_o/a_o) = 1.58$. The application of the theory of space groups to the x-ray data resulted in a unique soln. of the at. arrangement of $TiAl_3$, $4d$-8 (a, b, c, d). This soln. was verified by comparing the calcd. and observed intensities of the powder reflections. C. L. MANTELL

Fabrication of chromium-nickel-iron alloys. J. S. EWING. *Proc. Am. Assoc. Textile Chem. Colorists* 1931, 13–5; *Am. Dyestuff Reptr.* 20, 15–7(1930).—An alloy contg. 8% Ni and 18% Cr is austenitic in character and nonmagnetic; tensile strength 90,000 lbs./sq. in.; yield point 45,000 lbs./sq. in.; hot-working range 2150–1750°F. It can be arc-, gas-, resistance- or spot-welded. MILTON HARRIS

The influence of third metals upon the constitution of the brasses. III. The influence of tin. O. BAUER AND M. HANSEN. *Z. Metallkunde* 22, 387–91(1930); cf. *C. A.* 24, 2094.—A continuation of the comprehensive work of B. and H. on ternary brasses. Earlier work upon the Sn–Zn–Cu system is critically reviewed here. ROBERT F. MEHL

Deposition of black copper oxide on brass. HENRY L. KELLNER AND HARRY A. CURTIS. *Ind. Eng. Chem.* 22, 1321–4(1930).—An investigation of the "black-bronzing" of brass, carried out by dipping the cleaned brass in a bath composed of basic Cu car-

bonate and aqua ammonia, revealed that the Cu carbonate does not dissolve as such but decomposes, the carbonate and some of the hydrate going into soln., leaving a residue of partially dehydrated hydroxide. The bath corrodes the surface of the brass, and the black deposit, which consists of partially hydrated CuO, is laid down over the roughened surface. This deposit is translucent when viewed under the microscope.

Die pressing of brass and copper alloys. JOHN R. FREEMAN, JR. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 391, 8 pp.(1931).—The die pressing or hot forging of brass and Cu alloys is discussed, including the advantages of die pressings as compared to castings. A description is given of shearing the slugs from extruded rods or shapes; and the different types and relative advantages of crank, drop and screw presses are discussed. The importance of die design is emphasized. Types of dies are illustrated by drawings.
C. L. MANTELL

Effect of combinations of strain and heat treatment on properties of some age-hardening copper alloys. W. C. ELLIS AND EARLE E. SCHUMACHER. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 395, 13 pp.(1931).—For the purpose of developing combinations of higher strength and cond. than are obtainable by heat treatment alone in the age-hardening Cu alloys, an investigation has been made of the effects of combinations of heat treatment and strain hardening on the properties in question. Hard drawing after heat treatment increased the tensile strength of a Cu-Ni-Si alloy contg. 4% of Ni plus Si from 113,000 to 148,000 lb./sq. in. The properties of the alloy were further improved after hard drawing by low-temp. aging. Aging for 4 hrs. at 300° increased the cond. 19% without appreciably decreasing the tensile strength. Strain was found to accelerate pptn. in this system, which is in line with observations on other dispersion hardening systems. Cu alloys contg. Co and Si did not show as pronounced aging effects after hard drawing as did the Cu-Ni-Si alloys. As a result of the study a material suitable for use as an elec. conductor combining high strength with reasonably high cond. has been developed. Representative values for strength of this material are 145,000 lb./sq. in. combined with an elec. cond. of 38% that of annealed Cu.
C. L. M.

Age-hardening mechanism in copper-aluminum alloys. SADAJIRO KOKUBO AND KÔTARÔ HONDA. *Sci. Repts. Tôhoku Imp. Univ.* 1st. Ser. 19, 365–409(1930); cf. *C. A.* 24, 5208.—Specimens contg. from 0 to 12% Cu were heated for 30 min. at 545° and then quenched in water at 15°. After aging for 10–20 days at room temp., each specimen was heated for 6 hrs. at different temp. up to 500°, then cooled slowly in the furnace. The d., elec. resistance and hardness were than detd. and the relation between the changes in these qualities and the Cu content were studied. The dilation and thermal curves for quenched specimens were also taken during slow heating. The d., elec. resistance and hardness of Al-Cu alloys contg. from 0 to 12% Cu are greater in the quenched than in the forged state. The amt. of this difference increases with the content of Cu. During aging at temps. below 150° the d. and the hardness of the alloys increase with time, rapidly at first and then slowly, tending to a max., but the elec. resistance, while increasing at first, decreases afterwards. The change in elec. resistance, due to a given period of aging at 30°, increases linearly with the content of Cu up to 6% and decreases afterwards. The alloys were first quenched, aged at room temp. and then heated for 6 hrs. at different temps. After a slow cooling, their d., elec. resistance and hardness were detd. During heating the d. is slightly increased, reaches a max. at 150° and then begins to decrease. In the same range of temp. the resistance continuously decreases. The hardness decreases slightly at first and shows an inconspicuous min. at 60°. Afterwards it increases rapidly, attaining a conspicuous max at 70°. The d. falls rapidly in the range 170–270°, attaining a conspicuous min at 2[illegible] The elec. resistance and the hardness also show similar decreases in the same range of temp. In the range 270–500° the d. increases rapidly, finally nearly reaching its initial value. The elec. resistance decreases at first but shows a slight increase afterwards. The magnitude of these changes increases linearly with the Cu content of the alloys up to 6%, but decreases linearly afterwards. The age-hardening of Al-Cu alloys is being explained on the basis of Konno's theory and the untenability of the pptn. theory demonstrated.
LEOPOLD PESSEL

The nature of the β-transformation in copper-tin alloys. I. HIROSHI IMAI AND ICHIJI OBIN. *Mem. Ryojun Coll. Eng.* 3, No. 2C, 117–35(1930).—A no. of Cu-Sn alloys ranging in compn. from 20.22 to 33.13% Sn were sand-cast in round bars. After being annealed for 50 hrs. at 700° the sample rods were studied both in the fully annealed state and in the chilled condition (1) by means of measurements of elec. resistance at different temps., (2) by plotting differential heating curves and (3) microscopically.

The results obtained suggest a eutectoid breakdown at 525° in the following sequence $\beta \longrightarrow \beta' \longrightarrow \beta'' \longrightarrow \alpha + \delta$. The martensitic needle structure observed in the β-solid soln. is ascribed to an incomplete transformation of β into β'. The thermal effect at 590° is probably due not to a change of phase but to a change in at. energy, comparable to the A_2-effect in Fe-C alloys. H. S. VAN KLOOSTER

Plasticity of copper-zinc alloys at elevated temperatures. ALAN MORRIS. *Am Inst. Mining Met. Eng., Tech. Pub.* No. 390, 9 pp.(1931).—A series of drop-hammer tests at elevated temps. has been made on brasses ranging upward from 62% Cu. The alloys usually considered most difficult to hot-work show the least plasticity. α-Brasses that have been heated so as to develop a large grain appear to have a greater tendency to crack than samples of the same alloy that have not been so overheated. A method of calcg. the av. resistance of the sample to the blow is offered, which may prove to be a means of correlating the work of various investigators, although they have used samples of different sizes and different weights of blow. The calcd. resistances of Pb, Sn, Al and Zn at room temp. are compared with the plastic flow points, as detd by ordinary test. The relation between these 2 quantities varies with the different metals. The calcd. resistance of Pb, Sn and Zn are much higher than the plastic flow points while in Al the difference is not so great. This difference is probably due chiefly to greatly increased speed of deformation under the hammer, but to some extent may be due to strain hardening. C. L. MANTELL

Studies upon the Widmanstätten structure. II. The copper-zinc alloys and the copper-aluminum alloys. ROBERT F. MEHL AND O. T MARZKE. *Am Inst. Mining Met. Eng., Tech. Pub.* No. 392, 32 pp.(1931); cf. *C. A.* **24**, 5195. The pptn of the α- and γ-phases from the β- in the Cu–Zn system and of the α- from the β- in the Cu–Al system have been studied. These alloys were of special interest since it was possible to ppt. phases of different crystal structures (α- and γ-) from the same basic lattice (β) and thus to decide unequivocally whether the structure of the parent lattice is solely determinative in the type of Widmanstätten structure obtained. It is shown that the α-ppt. in Cu–Zn alloys is in the form of true needles nearly parallel to the (111) direction in the β lattice. The true direction of the needles is in the neighborhood of (553), thus exhibiting 12 families. The etching effects of the α-needles show that the α lattice in each needle family bears the same relationship in orientation to the β lattice. The γ-ppt. on cooling or on quenching and reheating takes the form of stars, which on longer heating shrink into well defined polyhedrons. The atom plane in the β-lattice bounding these polyhedrons is the (110) plane, and the atom plane in the γ lattice is very probably also the (110) plane. Reasons are advanced for the formation of needles in the α-pptn. and of dodecahedrons in the γ-pptn. The formation of these 2 distinctly different types of Widmanstatten figure adds further support to the previously enunciated theory (*C. A.* **24**, 5195) that the type of Widmanstatten figure is controlled not entirely by the structure of the present solid soln. but by a cooperation between the lattices of the parent solid soln. and of the ppt. The pptn. of the α phase from the β- in the Cu–Al system is closely analogous to that in the Cu–Zn system. Because of the far-reaching structural analogies in metal systems, it is suggested that Widmanstätten structure analogies exist also. C. L. MANTELL

Equilibrium diagram of the iron-vanadium carbon system. MASAKICHI ŌYA. *Sci. Repts. Tôhoku Imp. Univ.* 1st Ser. **19**, 449–72(1930); cf. *C. A.* **24**, 4496. The equil. diagram of the Fe–V–C system, contg. under 9.9% C, has been detd by means of thermal, x-ray and microscopic analysis. No ternary compd. exists in this system, but 5 liquidus surfaces, for the γ, α, (Fe_3C), ϵ and β phases, exist. The following binary eutectic and peritectic reactions exist in this system: melt $\longrightarrow \gamma + (Fe_3C)$, melt $\longrightarrow \gamma + \epsilon$, melt $\longrightarrow (Fe_3C) + \epsilon$, melt $\longrightarrow \alpha + \epsilon$, melt $\longrightarrow \epsilon + \beta$, melt $\longrightarrow \alpha + \beta$ and $\delta +$ melt $\longrightarrow \gamma$. In this system, the following two ternary eutectic reactions and also a peritectoeutectic reaction take place: (1) melt $\longrightarrow \gamma + (Fe_3C) + \epsilon$, (2) melt $\longrightarrow \alpha + \beta + \epsilon$, (3) $\delta +$ melt $\longrightarrow \gamma + \epsilon$. The compns. and temps. of these non-variant points are as follows: (1) 3.4% V, 4.2% C, 1122°, (2) about 35.0% V, 1.0% C, (no temp. stated), (3) 7.0% V, 2.3% C, 1330°. In the region of the γ-phase there exist 3 soly. surfaces, on which α, ϵ and (Fe_3C), resp., begin to sep. and 3 binary eutectoid curves along which the reactions $\gamma \longrightarrow \alpha + \epsilon$, $\gamma \longrightarrow \alpha + (Fe_3C)$, and $\gamma \longrightarrow (Fe_3C) + \epsilon$ take place. A number of photomicrographs and the proposed equil. diagram are enclosed. L. P.

Crystal forms of galvanizer's dross and zinc-iron alloys. WALLACE G. IMHOFF. *Iron Age* **126**, 1772–5, 1853–4, 1932–4(1930); cf. *C. A.* **24**, 5706.—Galvanizer's dross is a mixt. of Zn with needle-like crystals of Zn-Fe alloy. These crystals are rhombohedrons when formed below 900°F. and pyramids of the first order in the hexagonal system when formed at 950°F. The crystals break down if the temp. is increased.

with the sepn. of Zn. The higher Fe crystals so formed take up Zn, however, if the temp. is lowered and revert to the original dross. The results showed conclusively that sweated dross does not give good metal and such practice should be abandoned since the metal changes back again when put in with good Zn and makes more dross by changing back to the lower form of alloy crystals. Any operations to obtain Zn from dross should be so performed as merely to crowd the Zn-Fe alloy crystals closer together at a temp. not over 850°F. R. S. DEAN

Zinc and zinc-alloy use in the automotive industry. I. ROBERT M. CURTS. *American Metal Market* **38**, No. 21, 13(1931).—A brief review of the part that Zn and its alloys have played in the past and a discussion of recent developments in Zn-base alloys, which have enhanced their field of use in the automotive field. This instalment covers electro-zincing, rolled Zn and rolled-Zn alloys. It is now possible to apply a very satisfactory Ni or Cr plate to rolled-Zn parts. W. H. BOYNTON

The influence of phosphorus in iron-carbon alloy. YOICHI YAMAMOTO. *Bull. Inst Phys. Chem. Research* (Tokyo) **9**, 838 51 (Abstracts 82 (in English) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, 271–3(1930). —The influence of C on the soly. of P and the mode of occurrence of Fe_3P have been investigated. The effects of P on Brinell hardness and on graphitization have been studied. When C was above 2.0% and P above 0.5%, flakey graphite sepd. No other results are given in the English abstract. J. B. AUSTIN

Examinations of metals and alloys for resistance against attack by salt solutions. I. Influence of variations of experimental conditions. E. MAASS AND W. WIEDERHOLT. *Korrosion und Metallschutz* **6**, 218–23(1930).—An investigation was made of the attack of mother liquors of sylvinite, carnallite and Glauber salt upon sheets of iron, electrolytic Cu, brass, Al and an Al alloy contg. 3% Mn, 2.5% Mg and 0.5% Sb. The extent of corrosion was detd. by the loss of wt. method. The attack is severest with Cu and less severe with Fe. Al stood up relatively well at room temp., but is severely attacked at 95–100°. The Al alloy showed the pit type of corrosion. With ordinary immersion methods the mother liquor of sylvinite shows the greatest corrosiveness, the mother liquor of carnallite shows less and the mother liquor of Glauber salt least. At higher temp. the carnallite liquor is more corrosive than sylvinite liquor, because of the dissocn. of the $MgCl_2$. By moving the sheets or the soln., the formation of protective layers in the Glauber salt soln. is disturbed. The losses of wt., therefore, are greater here than in sylvinite liquors under similar conditions. The corrosion is diminished by the exclusion of air, and increased 2.5 times by the introduction of O, 5.4 times by stirring the soln. and 8.6 times by heating the soln. to 95–100°. **II. Influence of solid salts upon metals and alloys.** *Ibid* 241–50. The attack of solid salts upon 40 different metal sheets was investigated by spreading the salts over the specimens and leaving them undisturbed for the period of one year, under atm. conditions as far as temp. and moisture was concerned, but protected against rain. The salts investigated were: $MgCl_2$, carnallite, Hartsalz, KCl, NaCl and $MgSO_4$. The metals investigated included Ni, Cu, Ni-Cu alloys, Ni-Fe-Cr alloys, bronze, brasses, Al, Al-alloy and a number of Fe and steel specimens. A detailed description of the corrosion pictures obtained is given. The corrosiveness of the salts decreased in the above mentioned order. None of the materials was found to be absolutely resistant. The Ni-Cr steels stood up fairly well against NaCl and $MgSO_4$, but showed slight pit attack under the other conditions. These steels, as well as the non ferrous metals, show the attack in isolated pits, while the ferrous metals generally show a more evenly distributed, although much more severe, attack. Aside from the Cr-Ni steels pure Ni showed the least attack. With increasing Cu content the pits become broader and more numerous. The Ni-Fe-Cr alloys show relatively little attack. The formation of a brown corrosion product indicated that the Fe in the alloy was being attacked. Among the Cu alloys electrolytic Cu stood up best. Bronze showed a similar behavior. Among the brasses, those contg. a mixture of α and β crystals were more severely attacked than the pure α-brasses and were covered with a white corrosion product. The α-brasses, with Cu varying between 63% and 72%, show no indication of any influence of this variation upon their corrosion resistance. The Al alloy showed more or less severe pit corrosion. Further development of the bronzes by proper choice of additional alloying constituents seems to offer some promise. LEOPOLD PESSEL

Fundamentals of corrosion. G. MASING. *Z. Metallkunde* **22**, 321–6(1930).—A review of theories. ROBERT F. MEHL.

Methods of corrosion testing. ERICH K. O. SCHMIDT. *Z. Metallkunde* **22**, 328–33 (1930). The testing methods for the detn. of corrosion resistance of light metal plates developed during the last 5 years at the Deut. Versuchsanstalt für Luftfahrt are de-

scribed and the different methods of evaluation given. The corrosion tests are reproduceable and agree well with practical experience. ROBERT F. MEHL

The corrosion of metals. G. L'HOIR. *Bull. assoc. étudiants école sup. brasserie univ. Louvain* 30, 101–6(1930).—A brief review of the electrolytic theory of corrosion and of the causes facilitating corrosion. A. PAPINEAU-COUTURE

Corrosion of metals. F. MÜLLER. *Z. angew. Chem.* 43, 225–9(1930).—A review of recent theories and expts B. C. A

Corrosion and metal protection in steam power plants. III. Examination of a cracked condenser tube. R. STUMPER. *Korrosion und Metallschutz* 6, 217–8(1930); cf. *C. A.* 24, 3299.—Examn. of a cracked brass condenser tube led to the conclusion that the cracking was due to severe internal stresses of the cold-drawn tube and not to any special form of corrosion. In order to prevent cracking, the tube should have been annealed after cold drawing, or if greater hardness was desired, it should have been heated to 250–300°. LEOPOLD PESSEL

Influence of sodium chloride solutions of different concentrations upon the course of the corrosion attack in the intermittent immersion test. ERICH K. O. SCHMIDT. *Korrosion und Metallschutz* 6, 250–5(1930).—Specimens of lautal, 0.5 mm. thick, were immersed in an intermittent immersion app. in NaCl solns. of 1, 3, 5, 10 and 20% concns. The extent of corrosion was detd. by examn. of the surface, of the microstructure and of the tensile qualities. The corrosion attack of the NaCl solns. of 3, 5, 10 and 20% concns. shows differences only at the beginning of the corrosion test but later becomes uniform. In the 1% NaCl soln., however, the corrosion attack is considerably less. The explanation for this phenomenon lies in the fact that, after the first corrosion attack has roughened the specimens, the quantity of the adhering liquid will be approx. the same, in spite of the different concn. As these salt solns. are gradually drying in the air, the further corrosion attack is caused by moist NaCl, the abs. quantity of which has little influence. L. P

The corrosive action of quenching solutions upon metals. T. LIEPUS AND H. OSTERBURG. *Metallwirtschaft* 9, 904–6, 926–7, 946–8(1930).—The most common quenching baths consist of aq. solns. of NaCl, $MgCl_2$, $CaCl_2$, or mixts. of these. In order to det. to what extent such solns. attack various metals at low temp., small sheets of carefully cleaned wrought Fe, Cu (contg. Cu_2O), Sn and Zn of high purity, and com. 99.5% Al, were placed in the solns. at —5° and under other conditions approximating those of com. practice. The metals were removed every 10 days for 90 days, weighed and exaind. The 6 solns. used were "Reinhartin," a com. prepn. contg. CaCl, $MgCl_2$ and org. addns.; KCl with 29.9% salt; alk. KCl with 29.9% salt plus 0.3% NaOH; NaCl with 22.4% salt; alk. NaCl with 22.4% salt plus 0.77% soda; and $MgCl_2$ with 20.6% salt. The expts. showed that Sn resists the corrosive action of the solns. best of all, with Al second, Zn third, Cu fourth and Fe fifth. The usefulness of the cooling baths depends largely upon the metal used, the alk. solns. being the most favorable with Fe, but with Zn and Al the most unfavorable. CURTIS L. WILSON

Mode of action of corrosion inhibitors in metal pickling. H. PIRAK AND W. WENZEL. *Metallborse* 20, 2539–40, 2589(1930).—A review of various theories. Some preference is given to that of Chappell, Roetheli and McCarty (*C. A.* 22, 2910). L. E. GILSON

Corrosion and protection against corrosion in rolled aluminum alloys used in aircraft. P. BRENNER. *Z. Metallkunde* 22, 348–55(1930).—The influence of heat-treatment and cold-working upon the corrosion resistance of duralumin and other age-hardening Al alloys is discussed. For aircraft manuf. the new alloy "Duralumin-Legierungen ZB" is important because of its increased strength, higher elastic limit and yield point without diminished corrosion resistance. The improvement in corrosion resistance from artificial oxide coatings and by platings is marked. The improvement may be made even greater by a combination of the 2 methods. ROBERT F. MEHL

Action of oxygen on the corrosion of iron and steel in aqueous solution. HIKOZÔ ENDO AND SHIGENORI KANAZAWA. *Sci. Rept. Tôhoku Imp. Univ.* 1st Ser. 19, 425–35 (1930).—Expts. were carried out to investigate the action of dissolved O upon the corrosion of Fe and steel. By means of potential measurements the theory of O concn. cells was confirmed. The corrosion of Fe and steel in aq. solns. is considered to take place in 2 stages, and dissolved O is thought to have an accelerating effect upon both of them. The primary action of dissolved O lies in the formation of concn. cells and the ensuing acceleration of the soln. of Fe, forming a soln. of ferrous ion. The secondary action of O concerns the removal of the H film and the oxidation of the $Fe(OH)_2$. Various phenomena of corrosion are explained by considering these 2 sep. factors. LEOPOLD PESSEL

Corrosion and heat resistant nickel-copper-chromium cast iron. J. S. VANICK AND P. D. MERICA. *Iron & Steel Can.* 13, 241–2, 260–1, 263(1930).—The development of a cast Fe contg. approx. 14% Ni, 6% Cu, 2–3% Cr, 3% C and as much Si as ordinary cast Fe is described and the qualities of this material are discussed. Amsler wear tests of the brake shoe type indicated a wear resistance approx. 5 times that of ordinary cast Fe. The arbitration bar transverse strength can be varied between 2500 and 4000 lbs., the arbitration bar transverse deflection between 0.2 and 0.3 in., the tensile strength between 20,000 and 35,000 lb./sq. in. Izod impact tests, made with a special light-wt. hammer, gave readings of 80–110 ft.-lb., as against 9–15 ft.-lb. in ordinary cast Fe. Corrosion data are given showing the superiority of this material in comparison with ordinary cast Fe. In some cases it gives even better results than brasses and bronzes and can then be substituted for them, usually at a lower cost. It is especially recommended for contact with relatively strong acids and has a low corrosion rate in caustics, organic acids, tap water and the atmosphere. The heat resistance of this material in an oxidizing atmosphere is considerable in the range of 1200–1500°F. and may be 12–15 times greater than that of plain cast Fe under the same conditions. In the range of 1600–1700°F, however, this diff. is considerably decreased. It also resists well the combined attack of high temp. and chem. corrosion. It shows less growth at elevated temp. than ordinary cast Fe because of its austenitic character; it shows less tendency to graphitization; and its loss of strength at increased temp. is also smaller. The alloy is non-magnetic and has a high elec. resistance (1.75 % of the cond. of Cu). By special heat treatment it can be made magnetic or non-magnetic. The coeff. of thermal expansion is 50% greater than that of ordinary cast Fe and is similar to that of bronze. This feature may render the material important for sleeves in combustion engines. Up to 2% Cr the material has the machinability of cast Fe, which is reduced, however, if the Cr content exceeds 3%. The material can readily be welded by arc or acetylene, giving a soft, machinable weld. It is also suitable as a filler rod for the welding of ordinary cast Fe. LEOPOLD PESSEL

Knowledge of the corrosion process from the corrosion of copper-bearing steel. C. CARIUS. *Z. Metallkunde* 22, 337–41(1930); cf. *C. A.* 24, 1835, 2411.—It is concluded that an enrichment of Cu upon the surface takes place during the rusting of Cu-bearing steel. The manner of formation of the Cu ppt.—coherent ppt. during rusting in distd. water, incoherent during rusting in salt solns.—influences the rusting process fundamentally. By comparison of the oxidation potential of an aq. corrosion agent with the characteristic potential of the metal, a conception of the susceptibility of the metal toward attack by the soln. concerned may be obtained. The smaller the difference with respect to the oxidation potential of the soln., the smaller is the attack in the case where the metal has the tendency to pass into soln. as ions. R. F. M.

The corrosion of lead and its significance in a general knowledge of corrosion. M. WERNER. *Z. Metallkunde* 22, 342–6(1930).—Grain size plays a role in the corrosion of Pb but not more so than in the corrosion of other metals. The addn. of other metal forming local elements helps only if a passive layer is formed. The occurrence of a eutectic between Pb and the added metal can nullify the improvement. If the passive layer does not form, the effect of local elements is just as harmful as in other known cases. The changes in corrosive behavior from cold-work do not appear with Pb because of its recrystn. at room temp. The best lead from a corrosion-resistance standpoint is probably that least contaminated with O. The lack of trustworthy methods of test makes the study of the corrosion of lead difficult. Attempts should be made to develop sound methods. ROBERT F. MEHL

The periodical inspection of the first series of painted steel plates exposed to aerial corrosion at Southampton. J. A. NEWTON FRIEND. *Dept. Sci. Ind. Research, Deterioration of Structures in Sea Water, 11th. Rept. Comm. of the Inst. Civil Eng.* 1930, 6; cf. *C. A.* 24, 3977.—These plates have now been exposed more than 5 yrs. Galvanized plates are still in good condition, as are those covered with 2 or 3 coats of Fe_2O_3, although a few of the latter have begun to rust. Asphaltum paints continue to be as bad as coal-tar varnish. Dehydrated coal-tar has roughened and rusted somewhat, but the plates with coal-tar over red lead are still in good condition. I. H. ODELL

Examination of the tarred steel plates exposed at Weston-super-Mare and at Southampton (third series of painted plates). J. A. NEWTON FRIEND. *Dept. Sci. Ind. Research, Deterioration of Structures in Sea Water, 11th. Rept. Comm. of the Inst. Civil Eng.* 1930, 7–9; cf. *C. A.* 24, 3978.—This final report covers exposures of 28.5 months at Southampton and 17.5 months at Weston-super-Mare. Addn. of CaO to horizontal-retort tar had a beneficial effect, but this was not observed in the case of vertical-retort tar. Paraffin wax (5%) usually improved the protection of the latter.

The results as to temp. of application were similar to those given in the last report, the conclusion is that the plates need only to be warm enough to insure complete dryness, and the tar hot enough for the requisite fluidity. Plates tarred with the mill-scale still adherent were in good condition except where the scale was broken.
I. H. ODELL

Fatigue strength of welded steel joints. W. HOFFMANN. *Z. Ver. deut. Ing.* **74,** 1561–4(1930).—Welded pipe joints have an av. vibratory strength about 50% that of the material. The strength is influenced by the width and thickness of the weld as well as the ease with which the material is welded. The nature of the fluxing material is also of importance to the strength of the weld. Red short welds show little fatigue resistance. In general, burning depth should be as deep as possible and the weld should have a flat surface. Both impact and vibratory fatigue strength are higher for welded joints than for riveted joints. H. STOERTZ

X-ray inspection of welds in pressure vessels. ANGEL ST. JOHN. *Iron Age* 126, 1828–32(1930).—A detailed description of the x-ray equipment in use by the Babcock & Wilcox Co. for the testing of welds. R. S. DEAN

Significance of acetylene welding for the construction of apparatus in large-scale chemical manufacture. H. HOLLER. *Z. Ver. deut. Ing* **72,** 1579–84(1930).—The high development of acetylene welding has now made it possible to use all tech. metals in the construction of large equipment for the chem. industry. The significance of this is discussed. H. STOERTZ

Technical safety questions in acetylene welding. EDUARD SAUERBREI. *Z. Ver. deut. Ing.* **74,** 1591–5(1930).—A discussion of the various *causes of explosions* in acetylene welding, including the formation of detonating gas and the possibility of igniting explosive mixts. Air penetrates into the equipment in a number of ways, among them removal of sludge and renewal of H_2O. Ignition of C_2H_2-air mixts. is brought about by spark formation, incandescent carbide, open flames, striking back of flames, sucking back of O during the welding operation and handling frozen equipment.
H. STOERTZ

Influence of nitrogen upon electric arc welding. JULIUS FUCHS. *Z. Ver. deut. Ing.* **74,** 1569–72(1930).—The effect of N content (0.034–0.150%) upon the mech. properties of welds was studied. No very definite effect was observed, but it was found that bare com. wire could not be used for elec. welding. H. STOERTZ

Significance of burning depth in arc welding and means for its improvement. ERNST SCHWARZ. *Z. Ver. deut. Ing.* **74,** 1565–7(1930).—Welding wires with low C content give a greater burning depth. Diminishing the velocity of feed and increasing the welding current also increase burning depth within certain limits. As the most favorable burning depth the following recommendations are made for various types of welds: butt welds 2 mm.; for V-welds the depth must be at least sufficient that hollow space in the vertex of the angle be avoided; for cast Fe welds the greatest possible depth attainable should be used. H. STOERTZ

The diffusion of zinc into tin and lead into tin in the liquid state. (A contribution to the kinetics of the soldering process.) A. MERZ AND E. BRENNECKE. *Z. Metallkunde* **22,** 234–7(1930).—Conclusion of previous article (*C. A.* **24,** 3977). From the Nernst theory of reaction velocity in heterogeneous systems and the principle of the slowest reaction the diffusion const. is deduced as the essential factor for the velocity of the soldering process. It is shown that for the systems "solid Zn–liquid Sn" and "solid Pb–liquid Sn" the process of merging of the solid and the solvent is defined merely by soln. and diffusion. Contact between solid Cu and liquid Sn leads to the formation of Cu_3Sn which inhibits the interaction of the 2 metals. The diffusion consts. for the metal pairs Zn-Sn and Pb-Sn were detd. in the temp. range 260–360° according to the Graham-Stefan method; an app. for performing this detn. is described. Likewise the temp. coeffs. of the diffusion consts. for Zn-Sn (260–370°) and for Pb-Sn (260–555°) were detd. The diffusion consts. are independent of the concn. in the ranges studied. ROBERT F. MEHL

Apparatus **for grinding and classifying ores.** HENRY G. LYKKEN. Fr. 691,943, Mar. 14, 1930.

Aerating **apparatus for flotation plant for ores, etc.** CESAG CENTRAL-EUROPÄISCHE SCHWIMM AUFBEREITUNGS-A.-G. (Robert C. Gibbs, inventor). Ger. 513,119, Jan. 22, 1929.

Aerating **apparatus for flotation plant for ores, etc.** CESAG CENTRAL-EUROPÄISCHE SCHWIMM AUFBEREITUNGS-A.-G. Ger. 514,337, Feb. 17, 1929. Addn. to 513,119 (preceding abstr.).

Extracting **iron, etc.** ALLGEMEINE ELEKTRICITÄTS-GES. Ger. 513,110, Sept. 22,

1926. **Fe ores are reduced by heating with coke obtained by the low-temp. distn. of fuels, the reduction retort being heated by combustion of the gases obtained from the fuels.** The oven in which the fuels are distd. is heated by the hot gases from the reduction retort. If addnl. heat is required for the reduction, the tar is not sepd. from the fuel distn. products, but these are cracked by leading them over the hot coke. The spongy Fe or steel obtained is melted by an elec. arc arranged at the discharge end of the retort. Other metals may be extd. similarly.

Removing iron from bauxite. WILHELM GAUS (to I. G. Farbenind A.-G.). U. S. 1,789,813, Jan. 20. The bauxite is treated with water gas at a temp. of about 250° and a pressure of about 100 atm. and the Fe carbonyl thus formed is removed.

Roasting iron ores. HUNDT & WEBER G. M. B. H. Ger. 511,385, Oct. 20, 1928. Economy of fuel is effected by excluding air during the roasting. Gases contg. CO are then evolved from the ore, and are burnt to provide heat for the process. The gases may be enriched with solid, gaseous or liquid fuel, or by passing them over glowing C, or by removing CO_2. Also, fuel may be mixed with the ore. The treatment is particularly applicable to spathic iron ore and spherosiderite, but not to carbonaceous iron stone.

Roasting or sintering fine ore materials such as zinc ores. ADOLPHE D. H. J. FASSOTTE. U. S. 1,789,895, Jan. 20. The material is preliminarily subjected to a mixing and thread-forming operation in which threads of uniform small diam. are expressed against a conveyer band which is uniformly moved without shaking, being bent by the movement of the conveyer and broken into substantially uniform short pieces; these are allowed to dry and then subjected to blast roasting in thin layers. App. is described.

Roasting sulfide ore. AKTIESELSKAPET MALMINDUSTRI. Norw. 46,434, Dec. 30, 1929. The ore is roasted at such high pressures that the gas leaves the app. at the same pressure, for instance, 3 atm., under which the subsequent absorption is carried out.

Extracting metal values from sulfidic ores. ALBERT E. SMAIL. U. S. 1,780,032, Jan. 20. In treating materials contg. ferrous and non-ferrous metal sulfides assocd. with precious metal values, for recovery of all the metal values, by roasting to produce max. soly. of the non-ferrous values except precious metals, and max. insoly. of the ferrous values, followed by leaching to remove the sol. values, the leached residue contg. precious metal values is subjected to selective gravity classification to concentrate the precious metal values and segregate for recovery of assocd. metal values. Numerous details of procedure are described.

Removing arsenic from tungsten ore. JOSEPH H. BRENNAN (to Electro Metallurgical Co.). U. S. 1,790,088, Jan. 27. Free S is added to the ore and the latter is heated to above the b. p. of S and sufficiently high to volatilize the major portion of the As present.

Removing copper from molybdenite. M. RAEDER. Norw. 44,764, Dec. 31, 1928. Cupriferous molybdenite concentrate is heated in the absence of air and oxidizing gases to a temp. above the decompn. temp. of chalcopyrite but below the decompn. temp. of molybdenite, after which Cu is extd. by treating with acid solns. of tervalent metals, preferably a soln. of $Fe_2(SO_4)_3$ in dil. H_2SO_4. The ferrous salt formed may be continuously reoxidized by the introduction of hot air during the extn.

Treating cupriferous purple ore. AKTIESELSKAPET NORSK STAAL (ELEKTRISK GAS-REDUKTION). Norw. 42,301, Dec. 31, 1928. Purple ore is treated with a reducing gas to convert Fe_2O_3 to Fe_3O_4. The reaction product is sepd. magnetically. The magnetic material contains, beside Fe_3O_4, the Cu in easily sol. form. This is sepd. by leaching.

Working up aluminiferous materials. VEREINIGTE ALUMINIUM-WERKE A.-G. Ger. 512,564, Dec. 25, 1929. Minerals contg. Al, especially bauxite, are subjected to a preliminary working up by briquetting with pyrites mixed with sufficient powd. Fe to combine with the S, and smelting with C.

Briquets of magnetite. EMIL EDWIN. Norw. 43,721, Dec. 31, 1928. Spongy iron is pressed into briquets of a sp. gr. approx. that which is obtained by complete gas reduction of compact magnetite. The briquets are then treated with H_2O or CO_2 at high temp.

Extracting metals by cementation. EMANUEL FEUER. Austrian 119,939, June 15, 1930. The initial material is treated in the solid phase, preferably in suspension in a liquid. Thus, $PbSO_4$ may be treated with Fe in a rotary drum at 80°.

Extracting precious metals by amalgamation. DIEDERICK ENZLIN and JOHN A. EKLUND. Ger. 511,334, Aug. 19, 1928. See Brit. 320,185 (*C. A.* 24, 2415).

Crucible arrangement for metal founding. WALTER ARCONIA. Ger. 511,531, Feb. 9, 1929.

Parting-material for foundry molds. KELLY GRAPHITE MILLS. Brit. 334,857, June 5, 1929. See Fr. 677,093 (*C. A.* **24**, 3092).

Method and plant for making tubes, etc., by centrifugal casting. OSTERMANN & [illegible] A.-G. Ger. 514,201, May 27, 1928.

Method of making hollow metal bodies by centrifugal casting in unbaked greensand molds. SOC. ANON. DES HAUTS FOURNEAUX & FONDERIES DE PONT-A-MOUSSON. Ger. 514,153, Sept. 13, 1925.

Casting metals. BRUNO FASSL. Austrian 119,999, June 15, 1930. Addn. to 117,528. The method of mfg. hollow metal castings described in Austrian 117,528 (*C. A.* **24**, 3479) is modified by using a compound core comprising a metal annulus surrounding a carrier made of clay, chamotte, etc. Attainment of the proper wt. ratio between core and casting is thus facilitated.

Casting and brazing locomotive plates. METALLGESELLSCHAFT A.-G. (Paul Hartung, inventor). Ger. 511,750, Apr. 17, 1928.

Aluminum ingots. ALUMINIUM, LTD. Fr. 690,914, Feb. 11, 1930. In making ingots of Al or its alloys, an improved product is obtained by causing a progressive solidification from the base upward while applying heat to the unsolidified portion above the solidification plane.

Finely divided metals. I. G. FARBENIND. A.-G. Fr. 690,991, Mar. 3, 1930. In the thermal decompn. of carbonyl compds. under vacuum to obtain finely divided metals the heat for the decompn. is supplied partly from the outside through the walls of the furnace and partly from an internal source of heat. Cf. *C. A.* **25**, 907.

Pure metals. I. G. FARBENIND. A.-G. (Carl Müller and Walter Schubardt, inventors). Ger. 511,564, July 7, 1926. Addn. to 500,692 (*C. A.* **25**, 481). The method of 500,564 for prepg. pure Fe by the thermic decompn. of $Fe(CO)_4$ is extended to other metals. $Co(CO)_4$ alone or mixed with $Fe(CO)_4$ is heated in a current of indifferent gas or vapor to produce Co or Co + Fe. The carbonyls of Ni and Mo may be similarly decompd. Cf. *C. A.* **24**, 3480.

Copper. REYMERSHOLMS GAMLA INDUSTRI AKTIEBOLAG. Ger. 513,149, Oct. 3, 1929. Pyrites is roasted under chloridizing conditions and then extd. with water in 2 stages. The first ext. contains mostly chlorides, and the second ext. contains mostly sulfates. Cu is pptd. from the first ext. as $Cu(OH)_2$ or $CuCO_3$, and from the second ext. as CuCl. The ppts. are sludged together in a chloride soln. and treated with Fe to ppt. the Cu. Details are given.

Purification of copper. EPAMINONDA CRIVELLI. Fr. 691,632, Mar. 10, 1930. Subdivided Cu is purified by deoxidizing it by heat in the presence of a suitable reducing agent with rapid cooling of the mass out of contact with the air, *e. g.*, by rapid immersion in water. The mass is then immersed in a bath which will dissolve the impurities and finally washed.

Device for condensing zinc. FRANZ JURETZKA. Ger. 511,484, Jan 27, 1927.

Condenser of metallic vapors such as those of zinc. GEORGE T. MAHLER, ERWIN C. HANEWERK and EARL H. BUNCE (to New Jersey Zinc Co.) U. S. 1,790,012, Jan. 27. Structural features.

Carbon articles. DEUTSCHE EDELSTAHLWERKE A.-G. Ger. 513,278, Sept. 21, 1928. Sugar charcoal is used for the manuf. of C articles for tech. purposes, *e. g.*, *metallurgical crucibles*. The charcoal is mixed with sugar soln., shaped and baked. It is then treated with sugar soln. and heated cautiously, these treatments being repeated several times. Finally, the article is heated to a temp. above 1000°.

Smelting furnace suitable for treating iron ore. JOHN T. MCCOURT. U. S. 1,789,[illegible], Jan. 20.

Smelting furnace fired with coal dust. WILHELM REITMEISTER. Ger. 511,665, June [illegible], 1929.

Annealing and smelting furnace. RUDOLF GUNKA. Ger. 511,596, Nov. 1, 1927. The furnace is heated by gaseous fuel and O or compressed air.

Furnace for annealing or other heat treatments of bars, tubes, metal strips, etc. A. SMALLWOOD and J. FALLON. Brit. 334,965, April 25, 1929. Structural features.

Metallurgical furnace suitable for heating sheets, etc. WM. H. SMITH. U. S. 1,789,[illegible]7, Jan 20. Structural features.

Furnace for heating metal sheets while suspended by their upper edges. E. GRIFFITHS. Brit. 335,234, May 21, 1929. Structural features.

Continuous heating furnace for heating billets, sheet bars, etc. ALBERT L. CULBERTSON. U. S. 1,789,966, Jan. 27. Structural features.

Arching and heat treating metal sheets such as those of ferrous metal. WM. E. WATKINS (to Copper Plate Sheet & Tube Co.). U. S. 1,789,853, Jan. 20. The arched

sheets are passed into a furnace, the crown of each sheet is preheated to relieve the tension within the sheet and each sheet is then uniformly heated throughout. App. is described

Cupola furnace. L. A. BENTLEY. Brit. 334,917, June 12, 1929.

Cupola furnace with forehearth and slag separator. BADISCHE MASCHINENFABRIK & EISENGIESSEREI VORM. G. SEBOLD and SEBOLD & NEFF. Ger. 514,328, Sept. 17, 1927.

Oil-fired cupola furnace, with refining hearth. PETER MARX. Ger. 511,242, Jan. 4, 1930. Addn. to 469,704 (*C. A.* **23**, 4922).

Regenerative open-hearth furnace. ALBERT W. SMITH and RICHARD B. JONES U. S. 1,790,172, Jan. 27.

Furnace for steel. LOUIS A. M. J. DE THY. Fr. 692,129, June 7, 1929. In a furnace for the direct production of steel, the ore and very finely powd. coal are in suspension or fall very slowly in a current of ascending reducing gases carried to a suitable temp

Lining for converters and metallurgical furnaces. COMPTOIR TECHNIQUE ALBERT KNAFF ET LÉON MAYER. Ger. 511,117, Oct. 19, 1928. Addn. to 469,863 (*C. A.* 23, 1488) Disintegrated sintered dolomite is mixed with finely ground pitch and up to 25% (calcd. on the pitch) of heavy tar oil. Mixing may be effected at high temp.

Cleaning metal surfaces. JACOB JANZ (Wilhelm Meyer, inventor). Ger. 513,451, May 25, 1928. A hydrosulfite is added to the known alk. cleaning baths, to remove oxide from the metal surface

Cleaning metals with acids. FRANK D. BURKE (to Passivation Products Co.) U. S. 1,789,805, Jan. 20. In processes such as pickling ferrous metals with H_2SO_4, action of the acid on the metal itself is inhibited by the addn. of a small proportion (suitably about 10% or less) of an α-amino acid such as cystine.

Detinning metal. PAUL MARTH. Ger. 512,749, Oct. 18, 1928. Metals coated with tin are treated with alkali soln. in the presence of metal, *e. g.*, Cu, Ag, Au, which have as small a soln. tension as Sn Oxidizing agents may be present and the process may be carried out under raised or reduced pressures.

Method and apparatus for producing metal powders for bronzing, etc. HARTSTOFF METALL A.-G. (HAMETAG). Ger. 511,369, Oct. 23, 1928. Addn to 410,514.

Rolls for cold-rolling metals. K. G. HALLIN. Brit. 334,929, May 13, 1929 Rolls are formed with an outer shell of cast iron or steel and a case of other metal such as cast, pressed or forged alloy steel (the shell after heating to hardening temp. being shrunk on the core).

Local case-hardening of metals. VEREINIGTE SCHWEISS- UND APPARATEBAU WERKE G. M. B. H. Ger. 513,465, July 25, 1929. The parts that are not to be hardened are protected by a metal coating comprising at least 1 metal melting above the hardening temp. and at least 1 metal melting below that temp. The metals constituting the coating may be alloyed with one another or may be applied successively or mixed, *e. g.*, by spraying. A mixt. or alloy comprising Cu 85, Pb 10 and Sn 5% is suitable.

Apparatus for annealing metal sheets. REGNIER EICKWORTH. Ger. 512,888, Dec. 22, 1926. Details of the app. are given.

Improving the electric conductivity of commercial aluminum. SIEMENS & HALSKE A.-G. (Georg Masing, inventor). Ger. 513,017, Aug. 22, 1926. The hammered metal is heated for more than 5 hrs. at a temp. between 100 and 270°.

Blowpipe apparatus for cutting metals by fusion. OBERBAU GES. and W. HUTMANN. Brit. 334,815, Dec 20, 1929 Structural features.

Permanent magnet. DEUTSCHE EDELSTAHLWERKE A.-G. Fr. 690,768, Feb 27, 1930. See U. S. 1,773,793 (*C. A.* **24**, 5016).

Plating pipes with metals such as zinc and lining them with enamel. KURT T. POTTHOFF (to U. S Galvanizing & Plating Equipment Corp.). U. S. 1,789,596, Jan. 20. Various details of procedure and automatic app. are described.

Lining steel bearing shells. FREDERICK C. JONES and VERNE SKILLMAN (to Bohn Aluminum & Brass Corp.). U. S. 1,789,979, Jan. 27. The surface of the shell is treated with a molten metal such as an alloy of Cu and Pb and a coating of lining metal such as similar alloy is cast on the surface of the shell while maintaining the shell substantially free from contact with the air. App. is described.

Iron. FRIEDRICH BORGGRÄFE. Ger. 511,219, Feb. 1, 1929. Addn. to 486,236. The method of Ger. 486,236 (*C. A.* **24**, 2101) is modified by adding Cu and S (or pyrites) to the charge, so that the final product contains S 0.15, Cu 0.2 and P 0.15% (all approx.) A product suitable for the manuf. of screw blanks and like machined parts is thus obtained

Iron. I. G. FARBENIND. A.-G. (Walter Schubardt and Leo Schlecht, inventors) Ger. 513,362, Jan. 14, 1928. See Brit. 318,499 (*C. A.* **24**, 2101).

Iron metallurgy. JOSEPH K. SMITH (to Granular Iron Co.). Can. 308,140, Jan. 27, 1931. Pyritic ores are mixed with coal and lime in a reducing vessel and the ore is reduced in a non-oxidizing atm. at a temp. below the m. p. of iron.

Iron for chemical apparatus. I. G. FARBENIND. A.-G. Brit. 334,926, April 15, 1929. The pure iron referred to in Brit. 293,077 (*C. A.* **23**, 1317) is rendered resistant to aging by heating above the crit. point Ac3 and quenching. The treatment may be repeated several times. The product is suitable for app. for various chem. reactions with gases, vapors or liquids contg. free or combined O, H or S.

Decomposition of iron carbonyl. VEREINIGTE STAHLWERKE A.-G. Fr. 691,557, Mar. 7, 1930. Heated quartz, corundum, glass, porcelain and other ceramic materials are used for receiving the deposit of Fe in the decompn. of Fe carbonyl. The Fe is easily removed from the above material.

Iron and steel. COMPTOIR TECHNIQUE ALBERT KNAFF ET LÉON MAYER. Fr. 692,314, Mar. 19, 1930. In the manuf. of soft Fe and steel the air is introduced not only at the bottom but also at the sides on a level with the surface of the bath of metal.

Special steel. FELIX P. THUAUD, PIERRE M. CROIZARD and CHARLES S. SAINT-DONAT. Fr. 692,124, June 7, 1929. A steel for tools contains besides Fe and C suitable proportions of Mn, Co, Cr, Mo, V, Ti, U and Si. The steel may be used for cutting-tools without the necessity for a heat treatment. An example given is C 0.6–1.2, Mn 2–14, Cr 15–25, Mo 8–15, Co 1–8, V 0.6–2, Ti 0.25–0.7, U 0.3–0.6 Si 0.25–0.5, P 0.03–0.05, S 0.025–0.04% and Fe the rest

Conditioning articles of manganese steel. TAYLOR-WHARTON IRON & STEEL CO. Brit. 335,076, Oct. 4, 1929. Articles of Mn steel are subjected to cold working before being put into use to prevent self-conditioning in service, the treatment being applicable to liner plates for ball or rod mills, crusher and hammer parts of mills, hollanders of paper making app., rag slitters, excavating teeth and tips, drill blades, chain links, chutes, wheels, etc. Alloys may be treated contg. 10–15% Mn together with various other specified ingredients and various details of manuf. and working of the alloys are described

Metals and alloys. JEAN DEBUIGNE. Ger. 513,112, Sept. 1, 1923. Metals and alloys, particularly Mn, free from C and having a low content of Si, are prepd. by an aluminothermic process in which inert substances, particularly slaked CaO, are added to the mixt. in such an amt. that the temp. is reduced sufficiently to prevent the reduction of SiO_2.

Alloys. N. V. PHILIPS' GLOEILAMPENFABRIEKEN. Fr. 691,823, Mar. 12, 1930. An elastic alloy contains Cu, Mn and about 4% of Si, *e. g.*, Cu 95.5, Mn 0.5 and Cu 4%.

Alloys. BRAUNSCHWEIGER HÜTTENWERK G.M.B.H. Ger. 513,273, July 3, 1926. Homogeneous compns. comprising a metal and a non-metal, *e. g.*, Al and graphite, are prepd. by mixing the non-metal with the fused metal *in vacuo*.

Alloys. I. G. FARBENIND A.-G. (Peter Assmann, inventor). Ger. 512,986, June 20, 1926 Objects with a strong resistance to the action of chemicals, especially HCl, are prepd. from Ag alloys contg. 80% Ag, 0–20% Al and 0–19.5% Mn

Alloys with high resistance to sea water. RICHARD MÜLLER. Ger. 513,016, Sept. 19, 1926. Al alloys contg. Mg 1–6 and Ti 0.05–1% are used for purposes for which a high resistance to sea water is required.

Alloys for electric contact terminals. A. PACZ. Brit. 335,081, Oct. 7, 1929. Alloys are formed of W or Mo 50–95, Cu 5–50 and Si 0.2–5.0%, and in some cases part of the Cu may be replaced by Ag and a metal of the Fe group may be present. Various details for making the alloys are described.

Thermal treatment of noble metal alloys. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER and W. C. HERAEUS G. M. B. H. Ger. 514,126, Apr. 18, 1925. Alloys contg. Au or Ag as the main constituent, together with Al and another metal forming an aluminide, are kept for 2–6 hrs. at 850–900°, chilled and then kept for 1–6 hrs. at 500–600°. Like alloys contg. Pt or Pd in place of Au or Ag are kept at 1150–1400° in the first stage, and at 500–900° in the last stage. The aluminide-forming metal may be Co, Ni, Fe or Cr, or (when Au is the main constituent) Cu, Pd or Pt, or (when Pt or Pd is the main constituent) Mo, W or Ta.

Aluminum alloys. METALLGES. A.-G. Brit. 335,105, Dec. 7, 1928. Al alloys are formed which contain Cu 1–6 and Zn 2–4%, together also with both Mg and Li, with or without Si, Ti, Mn, Ni, Cd, Ag or Cr. The Mg is preferably less than 1% and the Li less than 0.5%. The alloys may be heated to about 500°, quenched and then annealed at 100° or higher in cast or worked form.

Aluminum alloys. AKT.-GES. DER EISEN & STAHLWERKE VORM. GEORG FISCHER and METALLGUSSWERK SCHWARZWALD A.-G. Fr. 690,771, Feb. 27, 1930. An auto-refining

of Al alloys takes place by adding to the alloy ready for casting, 0.2–5% of an alloy of a binary metal and Mg, preferably Ni-Mg or Cu-Mg. Cf. *C. A.* **25**, 909.

Purifying aluminum and its alloys. ARMAND GODEFROID. Ger. 490,349, Apr. 1, 1926. To remove absorbed gases and non-metallic impurities from Al and its alloys these are heated above the m. p. so as to increase the amt. of gas absorbed, and are then subjected to reduced pressure, whereby a sudden and practically complete degasification occurs, the escaping gas carrying the non-metallic impurities to the surface of the molten metal. App. is shown.

Beryllium alloys. LEWIS J. KEELER (to Beryllium Corp. of America). U. S. 1,790,155, Jan. 27. A fused bath such as $2NaF.BeF_2$ is electrolyzed to liberate Be and there is alternately supplied to the bath a Be compd. such as Be oxide and a compd. of an alloying metal such as Cu carbonate so that the metals are liberated for alloying with each other.

Alloy for use with cast iron. AUGUSTUS F. MEEHAN (to Meehanite Metal Corp.). U. S. 1,790,552, Jan. 27. An alloy for use in the treatment or manuf. of cast iron comprises Si not less than about 50%, an alk. earth metal such as Ca over 25%, a metal such as Ni in a substantial proportion up to 5%, and a second alk. metal of the Ca–Mg group (such as Mg) in a quantity somewhat less than half the quantity of the first alk. metal.

Ferrochromium. KENNETH M. SIMPSON. Fr. 690,692, Feb. 26, 1930. Ferrochromium is prepd. by mixing chrome ore with a carbonaceous material as hard as coal and the mixt. is afterwards broken and heated in a tunnel furnace to a temp. between 1200 and 1450°. The reaction is completed after sepn. of the residual material from the metallic particles which result from the reduction.

Lead alloy containing antimony and bismuth. MARTIN THIELERS. Fr. 691,600, Mar. 8, 1930. See U. S. 1,779,784 (*C. A.* **25**, 66).

Alloys of lead, tin and copper. WM. J. MERTEN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,790,164, Jan. 27. In forming alloys contg. Pb 10–28, Sn 2–10, Cu 62–88% and minor impurities, the ingredients are melted together, CaC_2 is added to the molten alloy to facilitate dispersion of the Pb and the alloy is permitted to cool.

Magnesium alloys. THE DOW CHEMICAL CO. Fr. 692,240, Mar. 18, 1930. An alloy of Mg is made by stirring molten Mg with a reducible compd. of a metal to be alloyed with the Mg in a bath of molten diluent, such as the molten bath of an electrolytic cell producing metallic Mg. The process is particularly suitable for making alloys of Mg with Mn or Ce.

Magnesium and its alloys. I. G. FARBENIND. A.-G. Fr. 690,654, Feb. 25, 1930. The resistant properties, particularly resistance to compression, of Mg and its alloys are improved by lowering the speed of formation to at least half of the normal, and after cessation of the exterior forming forces, the metal is brought quickly to a temp. below that at which any modifications of size or disposition of the crystn. structure could take place.

Tough corrosion-resistant alloy steel. SHELLEY M. STOODY (to Stoody Co.). U. S. 1,790,177, Jan. 27. An alloy steel which is suitable for tools or welding rods contains C 1–4, Cr about 25–35, Ni about 5–15, Si about 3.5–8.0%, the remainder being principally Fe.

Sintered alloys containing tungsten carbide, etc. R. WALTER. Brit. 300,675, Dec. 3, 1928. Products are formed which contain 50–80% of W carbide or carbonitride or both, together with metals such as Fe, Mn, Ni, Co, Cr, W, Mo and U or their carbides. Free W 5–30% and some B may be present. Cf. *C. A.* **24**, 5712.

Zinc alloy containing copper and silver. LELAND E. WEMPLE and FLOYD A. ASHREN (to Illinois Zinc Co.). U. S. 1,789,854, Jan. 20. An alloy of substantially greater hardness than that of Zn contains Zn 100, Cu 0.25–2.0 parts and Ag 0.1–20% the quantity of the Cu. The alloy may be rolled into sheets or strips.

Alumino-thermic mixture. ELEKTRO-THERMIT G.M.B.H. Ger. 511,990, Apr. 18, 1929. Alloyed Fe and steel filings are added to the Al-Fe_2O_3 mixt.

Alumino-thermic mixture. TH. GOLDSCHMIDT A.-G. Ger. 511,991, June 22, 1929. A thermite compn is made by mixing powd. Al with the oxide obtained by heating Fe cylinders from 800° or 900° to 1250°. The $Fe_2O_3.Fe_3O_4$ mixt. so obtained contains FeO.

Thermocouple. OTTO FEUSZNER (to the firm W. C. Heraeus G.m.b.H.). U. S. 1,789,733, Jan. 20. At least one element of a thermocouple is composed of an alloy of more than 2 precious metals including a highly gas-absorptive Pt metal, a precious metal of group one of the periodic system and a third component which is another Pt group metal. The alloy may contain Pd 55, Pt 35 and Au 10% and may be associated with another element formed of steel contg. Ni or Cr.

Fusion welding of heavy-walled steel or iron tubes. AIR REDUCTION CO. Brit. 305,459, Dec. 10, 1928. App. and various details of heating and mech. treatment are described.

Welding with a flame produced from alkali-metal vapor and chlorine or other reactive gas. MICHAEL POLANYI and STEPHAN VON BOGDANDY. Ger. 514,289, Jan. 18, 1929.

Electrode for electric welding. LA SOUDURE ÉLECTRIQUE AUTOGÈNE S. A. Fr. 692,113, June 6, 1929. The electrodes are surrounded by a substance to form a flux containing 0.25–30% of Be in powder, or the metal forming the electrode such as Cu or Al is alloyed with Gl.

Coating welding or soldering "sticks" or electrodes. LA SOUDURE ÉLECTRIQUE AUTOGÈNE S. A. Ger. 511,329, July 12. 1928. See Brit. 314,400 (*C. A.* **24**, 1337–8).

Composition for soldering and welding. PER KVANAAS. Norw. 46,104, Feb. 11, 1929. A mixt. of cryolite, borax and boric acid is specified.

Soldering steel. HERMANN J. SCHIFFLER. Fr. 691,035, Mar. 3, 1930. Refractory Mo tools are soldered by using a refractory steel which does not contain Al as con[illegible] refractory metal.

10—ORGANIC CHEMISTRY

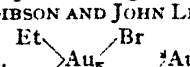
CHAS. A. ROUILLER AND CLARENCE J. WEST

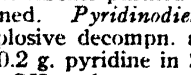
Advances in organic chemistry 1924–1928. Pyridine chemistry. HANS MAIER-[illegible] *Z. angew. Chem.* **44**, 49–55(1931). E. H.

Catalytic decomposition of some gaseous ethers. PAUL A. K. CLUSIUS. *J. Chem. Soc.* **1930**, 2607–15.—The catalytic effect of I on the decompn. of Me_2O, MeEtO, Me_2CHOMe and *tert*-BuOMe in the gaseous state has been investigated. I has no catalytic effect on the decompn. of Me_2O. MeOEt is catalytically decompd. between 450° and 550° according to the following consecutive reactions: $MeOEt \longrightarrow CH_4 + MeCHO$, $MeCHO \longrightarrow CH_4 + CO$. The heat of activation of the 1st reaction is 38,000 cals. Me_2CHOMe is decompd. simultaneously between 450–520° in 2 different ways: $Me_2CHOMe \longrightarrow CH_4 + Me_2CO$ and $Me_2CHOMe \longrightarrow CH_2O + C_3H_8 \longrightarrow CO + H_2 + C_3H_8$. The heat of activation is 29,500 cals. for the net reaction. Me_3COMe shows a very pronounced reaction in the presence of I but is not decompd. in a simple manner. The results illustrate clearly the fact that the activation of a reactant mol. is dependent upon the structure of the whole mol. and not upon the presence of a certain group. The catalyst attacks the mol. at a sp. point and the observed reactions can in every case be interpreted as the migration of a H atom from an O atom, which is also connected with an O atom, to a 2nd C atom. C. J. WEST

The action of nitrogen pentoxide on ethylene hydrocarbons. N. YA. DEM'YANOV. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, 447–51.—N_2O_5 with unsatd. hydrocarbons gives glycol nitrates and addn. products in which N is linked to C. $Me_2C:CMe_2$ (I) yields 3 cryst. substances of the latter type: $C_6H_{12}N_2O_6$, $C_6H_{12}N_2O_5$ and $C_6H_{12}N_2O_4$, which are reduced to pinacol, glycolamine and diamine, resp. No cryst. products could be isolated from $CH_2:CH_2$ (II) but the nitrate was detected by its explosive character, and glycolamine was obtained after reduction, indicating $C_2H_4N_2O_5$. Some $(CH_2NH_2)_2$ was also found. Haines and Adkins (cf. *C. A.* **19**, 1855), with a different method observed no reaction with II, and obtained no cryst. substances from I. They did observe the formation of green and blue compds. in soln. These are probably nitroso compds. D. finds that N_2O_5 adds easily to I and *cyclohexene*. Nitric esters are the principal reaction products; the dinitro compds., nitro alcs., and nitro nitrates are also formed. D. thinks the colored nitroso compds. may be intermediates according to the following scheme: $Me_2C(NO)C(NO_2)Me_2 + O \longrightarrow (Me_2CNO_2)_2$ and $Me_2C(NO)C(NO_2)Me_2 + O \longrightarrow Me_2C(NO_2)C(ONO_2)Me_2$. LEWIS W. BUTZ

Latent heats of evaporation of nitromethane and benzonitrile. JAMES C. PHILIP AND [illegible] C. WATERTON. *J. Chem. Soc.* **1930**, 2783–4.—The latent heats of evapn., with Campbell Brown's method (*J. Chem. Soc.* **83**, 987(1903)), for $MeNO_2$ and PhCN are found as 135.4 and 106.5 cal./g. With these figures the van't Hoff formula gives for Λ values 2.05 and 4.01, resp., only slightly higher than the exptl. values (1.86 and [illegible]). C. J. WEST





Interaction of ammonium sulfite with certain polybromoparaffins. WM. J. POPE AND [illegible] B. KIPPING. *J. Chem. Soc.* **1930**, 2591–4.—Attempts to prep. paraffin poly-SO_3H acids from I and II by interaction with aq. $(NH_4)_2SO_3$ have resulted in failure; in the former case a di-SO_3H acid was produced and in the latter, salts of isomeric SO_3H

acids were isolated. β,γ-Dimethylbutadiene (10 g.) and Br in AcOH give 28 g. of the *α,β,γ,δ-tetra-Br deriv.* (I), m. 138°; with $(NH_4)_2SO_3$, boiled 16 hrs., there results 80% of the *Ba β,γ-dimethylbutylenedisulfonate*, needles with 1 mol. H_2O; the salt absorbs 1 mol. Br; the free acid could not be obtained cryst. *NH_4 salt*, plates; *Na salt*, needles, *pyridine salt*, m. 215–6°; *acid chloride*, m. 125–6°. $(MeCHBr)_2$ (II) and $(NH_4)_2SO_3$, boiled 22 hrs., give a mixt. of *β-hydroxybutane-γ-sulfonic acids*, the *brucine salts* m. 270°, $[\alpha]^{20}_{5461}$ —23.9° (H_2O, *c* 0.58) (the *l-menthylamine salt* of this fraction m. 196°) and m. 180–5°, $[\alpha]^{20}_{5461}$ —29.6° (*c* 0.57). C. J. West

Reducing action and constitution of the Grignard reagent. C. R. Noller. *J. Am. Chem. Soc.* 53, 635–43(1931).— Solns. of $(iso\text{-}Bu)_2Mg$ which are practically halogen-free have been shown to reduce Ph_2CO to Ph_2CHOH, as well as the original Grignard reagent contg. halogen. The Grignard reagent prepd. from iso-BuBr at a concn of about 1.3 molar exists to the extent of 75% in the form of $(iso\text{-}Bu)_2Mg$. When the original Grignard reagent is used to reduce Ph_2CO, the reduction product ppts. as a white cryst. compd. which yields, on decompn. with H_2O, 1 mol. of Ph_2CHOH, 1 equiv. of basic hydroxyl and 1 equiv. of halogen. When a soln. of $(iso\text{-}Bu)_2Mg$ is used, the reduction product remains in soln. presumably in the form $(Ph_2CHO)_2Mg$, but can be pptd. by the addn. of a soln. of $MgBr_2$ to give a compd. identical by analysis with that obtained from the original Grignard soln. It is believed that the constitution of the Grignard reagent represented by the equil. $R_2Mg \cdot MgX_2 \rightleftarrows R_2Mg + MgX_2$ best fits these facts and that the Et_2O-insol. benzohydryl Mg salt has the compn $(Ph_2CHO)_2Mg\ MgBr_2$. C. J. West

The lability and relative reactivities of organic radicals. Henry Gilman, Edith L. St. John and L. L. Heck. *Proc. Iowa Acad. Sci.* 36, 269–70(1929). Studies have been made of the rates of many reactions involving organometallic compds., by means of the color test of Gilman and Schulze (*C. A.* 1, 2473; 22, 942). These rate studies comprise: (1) the relative reactivities of a variety of compds. toward a typical organometallic compd.; (2) the relative reactivities of a series of related compds. like nitriles or azo compds. with an organometallic compd., (3) and, the differences in rate of reaction of a series of organometallic compds. toward other compds. The same method has been used in a study of the effect of concn., temp. and catalysts on reaction rates. Also, it has been shown to be of service in a study of the mechanism of reactions, like the 2-stage conversion of esters to ketones to tertiary alcs., and the lability and relative electronegativities of radicals. W. G. Gaessler

The organic compounds of gold. I. Diethylgold bromide and some derivatives. Charles Stanley Gibson and John Lionel Simonsen. *J. Chem. Soc.* 1930, 2531–6

Diethylgold bromide,  (I), and some of its derivs. are prepd., it being proved that in these compds. Au has a coördination no. of 4. To obtain I (m. 58°), an EtMgBr soln. (from 6 g. Mg and 27 g. EtBr) is forced by a N_2 stream through a fine muslin filter into a $AuBr_3$ soln. (30 g. $AuBr_3$ in 250 cc. Et_2O) in a 3-necked flask with a stirrer and a condenser (the mixing taking about 1 hr., both solns. being cooled in a freezing mixt.), is stirred for 0.5 hr., the bath then replaced by cold H_2O, stirred for 0.5 hr. more, cooled in ice, powd. ice added (to avoid violent reaction), dil. HBr added, poured into a sepg. funnel, the Et_2O soln. sepd. and washed several times with H_2O (rejecting the first aq. soln.), the final Et_2O soln. dried rapidly with $CaCl_2$, evapd. first in a N_2 current under reduced pressure and at as low a temp. as possible and then completely in a desiccator over H_2SO_4, the residue treated with ligroin (b. 40–60°), filtered, the filtrate evapd. in a vacuum desiccator over H_2SO_4, and the cryst. residue further purified by washing with a little MeOH. Three g. of the desired I is obtained. *Pyridinodiethylgold bromide*, $Et_2AuBr\ C_5H_5N$, (m. 59–60° (decompn.) and explosive decompn. at 79°) is prepd. by mixing 0.5 g. I suspended in 1.5 cc. MeOH and 0.2 g. pyridine in 2 cc. MeOH, pptg. by adding H_2O, and purified by dissolving in MeOH and repptg. with H_2O. *Ethylenediaminodiethylgold bromide*, $[(CH_2NH_2)_2 \rightleftarrows AuEt_2]Br$ (plates, decompn. starting at 182°), seps. on adding a slight excess of $(CH_2NH_2)_2$ to a I-ligroin soln., and is crystd. from abs. alc. *Diethylgold acetylacetone*,  (II) (m. 9–10° (thermometer in liquid)), prepd. from a mixt. of 1.52 g. thallous acetylacetone suspended in abs. EtOH and Et_2AuBr 1.63 g. I in sufficient abs. EtOH, the mixt. stirred (finally at 40°), filtered and washed, the filtrate and washings evapd. over H_2SO_4 in a desiccator, the resi

due dissolved in ligroin (b. 40–60°), filtered, evapd., and crystd. *Diethylgold iodide* (III), corresponding to I (m. 67–8° and vigorous decompn. at 70–1°), is prepd. by adding H_2O to a mixt. of II and NaI (slight excess) in abs. alc., the ppt. sepd., dried, extd. with ligroin (b. 40–60°) and evapd. *Ethylenediaminodiethylgold iodide* (m. 162° (decompn.)) is prepd. from III and $(CH_2NH_2)_2$, similarly to the bromide. J. B.

The formation of diisobutylene from acetone under high pressure. A. D. Petrov and I. Z. Ivanov. *Bull. soc. chim.* [4], **47**, 1270–4(1930).—Me_2CO was heated under pressure to 280–300° in the presence of 10% of $ZnCl_2$. A considerable quantity of gas was obtained consisting of CO, paraffins and olefins of which 90% was C_2H_4. Of the portion of the liquid products b. to 150°, 50% distd. at 100–10°, consisting of branched-chain olefins, mainly $CMe_3CH_2CMe{:}CH_2$ (I). It is suggested that the C_2H_4 polymerizes to $Me_2C{:}CH_2$ and this, in turn, to I. These last reactions are known. The quantity of naphthenes formed in the decompn. of Me_2CO is very small. Also in *J. Russ. Phys.-Chem. Soc.* **62**, 1489–92(1930). I. M. Levine

Constitution of homomesityl oxide. S. G. Powell and C. H. Secoy. *J. Am. Chem. Soc.* **53**, 765–8(1931).—The structure of homomesityl oxide (I) is definitely established as $MeEtC{\cdot}CHCOEt$ by the following reactions: I is obtained in 85 g. yield from 500 g. 2-butanone by the use of BaO in place of CaC_2; it b. 164–6°, d_4^{21} 0.8633, n_D^{21} 1.4445. Catalytic reduction gives $MeEtCHCH_2COEt$ (II), b. 158°, d_4^{24} 0.829, n_D^{24} 1.412; semicarbazone, m. 96°; oxidation gives AcOH and $MeEtCHCH_2CO_2H$. Reduction of I with Na and moist Et_2O gives $MeEtCHCH_2CH(OH)Et$, b. 155°, d_4^{25} 0.8425, n_D^{24} 1.433. $EtMeCHCH_2MgBr$ and EtCHO give the same alc., which is oxidized to II. If I had the structure $EtMeC{\cdot}CMeCOMe$, it should give $EtMeCHCH_2MeCOMe$ on reduction; however, this compd., prepd. from Et *sec*-butylmethylacetoacetate, is different from II; it b. 158°, d_4^{22} 0.8295, n_D^{22} 1.412; semicarbazone, m. 124–6°. C. J. West

The decomposition of the optically active diazo ester from aminolauronic acid. P. P. Ray and W. R. Bunting. *Proc. Iowa Acad. Sci.* **36**, 271–4(1929); cf. *C. A.* **24**, 4017.—About 20 g. of the diazo compd. from the *cis*-acid was prepd. and decompd. This gives, on distn., an unsatd. fraction that corresponds to 60.5% of the distillate. R. and B. failed to find any of the ether acid that Skinner (*C. A.* **17**, 2270) found only in the decompn. of the *trans*-amino ester. The *cis*-diazo compd. follows the same course in its decompn. as the *cis*-amino acid. It is reasonable to suppose that the *trans*-diazo compd. will follow the course of the *trans*-amino ester. If the 2 diazo compds. give different products, it must be allowed that diazo C retains its asymmetry, as that is the only manner in which the 2 compds. differ W. G. Gaessler

Constituents of adsuki bean (Phaseolus radiatus, L. var. Aurea, Prain). E. Miyamoto and H. Yamada. *J. Pharm. Soc. Japan* **50**, 1095–1100(1930); German abstr. 147.—M. and Y. detd. the following constituents of adsuki bean: water 20.0%, fat 0.55%, fatty acids 0.71% (solid acids (I) 53.90% and liquid acids (II)) 46.10%, and saponin 0.27%. I contains palmitic, stearic and arachic acids and II linolic, linolenic and oleic acids. F. I. Nakamura

Action of phenylmagnesium bromide on ethyl diethylcyanoacetate. A. Mavrodin. *Compt. rend.* **191**, 1064–6(1930).—The first products obtained from the interaction between PhMgBr and $NCCEt_2CO_2Et$ (I) consists of Ph_2CO and *Et α-diethyl-γ-ethylbutyl acetate*, $Et_2CHCOCEt_2CO_2Et$ (II), b_{18} 138°. A suggested mechanism may be represented by the following series of equations: (a) $PhMgBr + I \longrightarrow PhCN + BrMgCEt_2CO_2Et$ (III), (b) $PhCN + PhMgBr \longrightarrow BrMgN{:}CPh_2 \longrightarrow HN{:}CPh_2 \longrightarrow Ph_2CO$, (c) 2 III $\longrightarrow$ $EtOMgBr + BrMgCEt_2COCEt_2CO_2Et \longrightarrow$ II. Sapon. of II yields $(Et_2CH)_2CO$. I. M. Levine
